	10^{-5}	Nil (6/6)	Inhibition of Ach. Average 3·3 ± 2·0 per cent (6/6)
	10^{-4}	Contraction (6/6)	Inhibition of Ach. Average 8·0 ± 3·03 per cent (6/6)
Cardiac muscle (isolated auricles of guinea pigs)	10^{-6}	Rate decreased (11/18)	Rate: inhibition of depression by Ach. (3/4). Average 13·75 ± 6·3 per cent
		Amp. increased (13/18)	Amp.: inhibition of depression by Ach. (3/4). Average 11·75 ± 7·3 per cent
	10^{-5}	Rate decreased (14/18)	Rate: inhibition of depression by Ach. (3/4). Average 38·5 ± 21·85 per cent
		Amp. decreased (9/18)	Amp.: inhibition of depression by Ach. (4/4). Average 30·5 ± 13·3 per cent
Smooth muscle	10^{-6}	Slight increase in tone (24/24)	Enhancement of contraction by Ach. Average 14·0 ± 3·14 per cent (6/6)
	10^{-5}	Contraction (24/24)	Inhibition of contraction by Ach. Average 24·1 ± 5·79 per cent (6/6)
	10^{-4}	Contraction (27/27)	Inhibition of contraction by Ach. Average 42·0 ± 7·4 per cent (6/6)

Figures in brackets indicate the number of times the effect was seen (numerator) out of a total number of observations made (denominator).

Table 2. COMPARATIVE ACTIONS OF PALUDRINE (REF. 2) AND AJMALINE AND THEIR RESPECTIVE EFFECTS ON THE ACTIONS OF ACETYLCHOLINE ON DIFFERENT TISSUES

Tissue examined	Drug	Drug alone		Drug plus acetylcholine			
		Effect	Dose (g/ml.) for the effect	Effect (No. 1)	Dose (g/ml.) for effect (No. 1)	Effect (No. 2)	Dose (g/ml.) for effect (No. 2)
Skeletal muscle (rectus abdominis of *Rana trigrana*)	Paludrine	Contraction	10^{-4}	Enhancement of acetylcholine action	5×10^{-7}	Inhibition of acetylcholine action	10^{-6} to 10^{-4}
	Ajmaline	,,	,,	,,	10^{-6}	,,	10^{-5} to 10^{-4}
Cardiac muscle (on rate and amplitude of beat of isolated auricles)	Paludrine	Inhibition	8×10^{-5}	Antagonization of acetylcholine action	8×10^{-5}	No information on the nicotinic action of acetylcholine	No information
	Ajmaline	,, (Note: amplitude increase at	10^{-5} and above 10^{-6})	,,	10^{-5}	Antagonization of the nicotinic action of acetylcholine	10^{-5}
Smooth muscle of guinea pig ileum	Paludrine	No information	No information	No information	No information	Inhibition of acetylcholine action	No information
	Ajmaline	Contraction	10^{-5} and above	Enhancement of acetylcholine action	10^{-6}	,,	10^{-5} to 10^{-4}

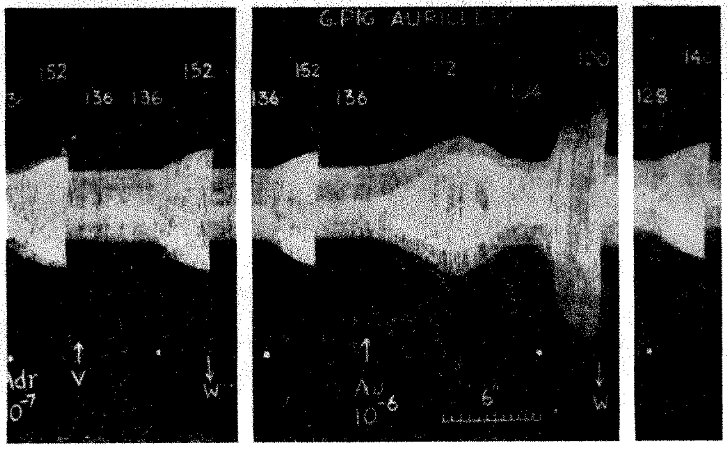

Fig. 1. Action of ajmaline alone and its modifying influence on the action of adrenaline on isolated auricles from guinea pig in 50 ml. bath at 29° C. At dots, adrenaline 10^{-7} g/ml. At *Aj*, ajmaline 10^{-6} g/ml., and at *V*, the corresponding vehicle added to bath, washed down at *W*. Note the increase of amplitude, depression of rate and prevention of cardio-accelerator action of adrenaline by ajmaline

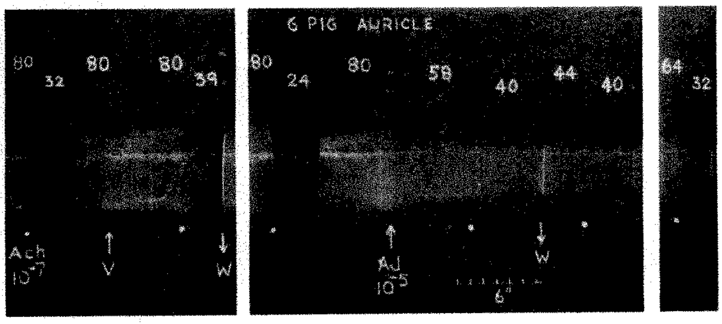

Fig. 2. Same as in Fig. 1 except that, at dots, acetylcholine 10^{-7} g/ml. is given. Note the depression of rate and amplitude by 10^{-5} g/ml. of ajmaline, and its anti-acetylcholine action

man La Roche), adrenaline tartrate (May and Baker) and noradrenaline bitartrate (Winthrop).

The results of the action of ajmaline on isolated muscles are presented in Table 1.

It has been noted that ajmaline has spasmogenic action on isolated smooth muscle preparations like guinea pig ileum and guinea pig seminal vesicles, and on isolated skeletal muscles, for example, frog rectus abdominis. On the other hand, ajmaline has depressive effects on the rate and amplitude of isolated perfused hearts of frogs and guinea pigs. In isolated auricles of both rabbits and guinea pigs, ajmaline depresses the rate but increases the amplitude (Fig. 1). High doses, however, depress both the rate and the amplitude of the auricles. The spasmogenic actions of acetylcholine on smooth and skeletal muscles are enhanced by low doses and antagonized by high doses of ajmaline. The ED_{50} of ajmaline for inhibiting contractions by acetylcholine in isolated guinea pig ileum was found to be $1 \cdot 26 \times 10^{-4}$ g/ml. The depression of rate and of amplitude of isolated auricles of guinea pigs and of isolated frog hearts caused by acetylcholine is antagonized by ajmaline (Fig. 2). The actions of adrenaline and noradrenaline in effecting an increase of the rate (cardio-acceleration) of isolated frog hearts and guinea pig auricles are antagonized by ajmaline, but the increases of amplitude caused by these catecholamines are not inhibited (Fig. 1).

The close similarity of the foregoing effects of ajmaline on the actions of acetylcholine, with those of paludrine as described by Vane[2], is shown in Table 2.

The foregoing results indicate that ajmaline reduces the cardiac rate in the same way as paludrine and other antiarrhythmic drugs, but the difference is that the reduction in rate is accompanied by an increase in amplitude when a lower concentration of ajmaline (10^{-6} g/ml.) is used. It shows, in addition, a specific anti-accelerator action (that is, inhibition of the action of adrenaline and noradrenaline on cardiac rate) which has not been described for paludrine or quinidine. This anti-accelerator property has, however, been shown to be possessed by veratrum alkaloids[9], but the latter has no antiarrhythmic property. This selective property of ajmaline in producing partial inhibition of adrenaline-action, namely, of only the increase of rate and not of amplitude after administration of adrenaline, is an additional factor in ajmaline over and above its antiacetylcholine action on isolated auricles of heart, which is a property common to both ajmaline and quinidine.

From the comparative results presented in Table 2 it is further evident that there is a very close similarity between ajmaline and paludrine so far as their cholinergic, antiacetylcholine and potentiation of cholinergic actions are concerned.

Dawes[1] postulated that drugs which inhibit the action of acetylcholine in smooth, skeletal and cardiac muscles have quinidine-like properties. This postulate was found to be satisfied by paludrine[2], which was also found to possess antiarrhythmic action. The investigation recorded here shows that ajmaline also fulfils these conditions.

Burn[3], in analysing the pharmacological actions of paludrine on isolated skeletal, cardiac and smooth muscles, suggested that drugs like paludrine act on cholinergic receptors and, therefore, can compete for such receptors.

From the point of view of this similarity (Table 2) and also because of the hypothesis of Burn[3] and Dawes[1], the conclusion becomes irresistible that ajmaline, like paludrine, acts on cholinergic receptors and can sensitize these in small concentration to enhance the action of acetylcholine, with which it can also compete at a higher dose-level and can antagonize the action of acetylcholine.

These findings on the action of ajmaline on cardiac functions offer an explanation for its useful therapeutic applicability[10] in cases of cardiac arrhythmias, for example, auricular fibrillation, and offer also a promise for its use in combination with a good antihypertensive agent like reserpine for treatment of cases of hypertension complicated by cardiac irregularities.

These experimental observations also lend support to the clinical finding[11] which shows that the extract of total alkaloids of *Rauwolfia serpentina* is preferable to a single alkaloid such as reserpine. Obviously, the beneficial pharmacological actions of ajmaline or similar alkaloids in the total alkaloid-extracts of *Rauwolfia serpentina* will counteract some of the undesirable effects, such as cardiac depression and even chances of cardiac failure, which have been met with after administration of reserpine alone[12].

We thank Dr. F. Gross, of Ciba, Ltd., and Dr. Debi Chakravarti, of Bethune College, Calcutta, for the supply of ajmaline.

TRANSPORT OF IONS ACROSS MEMBRANES

A Model for the Transport of Sodium and Potassium Ions

THE chemical reactions between nutriments cause a decrease of these substances and are a source of metabolic end-products in the living cell. As a result, the chemical reactions give rise to continuous vectorial processes with nutriments flowing in and end-products flowing out of the cell. Owing to coupling between processes of the same tensorial order, these processes may produce stationary non-equilibrium distributions even of substances present in the system the amounts of which are not changed by the chemical reactions[1,2]. Regarding the problem of the uneven distribution of Na^+ and K^+ ions in living systems, these considerations call for an examination of the distribution of these ions in stationary-state models that include processes produced by cellular metabolism.

Acids and water are continuously produced by oxidative metabolism and supplied from the cell to the extracellular fluid[2,3]. In the present work, the ion distributions have been investigated in a stationary-state system in which an acid and water are simultaneously supplied to an aqueous solution of sodium chloride and potassium chloride.

The apparatus (Fig. 1) was of the same type as that used by Teorell[3] and by Nims and Thurber[4]. It was made of 'Plexiglas' and consisted of a small chamber (10 ml.) containing a liquid phase α, and a large chamber (1,500 ml.) containing a liquid phase β. Both phases were stirred at constant rates. Between the phases there was a porous membrane ('Membranfilter No. 9', Membranfiltergesellschaft, Göttingen). Its area was 10 cm² and thickness 60μ; the average pore diameter was 125 mμ. The membrane as such was freely permeable to all the species in the aqueous solution of sodium chloride, potassium chloride, and hydrochloric acid.

The experiments were performed at room temperature; during the stationary state the temperature in phase β was 22° ± 1·5° C.

Phase β was composed of an aqueous solution of sodium chloride and potassium chloride. The system was brought to 'life' by filling the small chamber with an aqueous solution of hydrochloric acid and supplying this fluid continuously to phase α with hydrostatic pressure. The hydrochloric acid flowing through the membrane to phase β was neutralized to pH 7 by continuous addition of an aqueous solution of sodium hydroxide and potassium hydroxide to this phase. As a guide of its neutrality phase β contained a few drops of an indicator (bromothymol blue). The dilution effect of the water flowing to phase β was cancelled out by making the concentrations of Na^+ and K^+ in the base solution just so much higher than those in phase β that, when the acid solution was neutralized, the resulting solution had the same composition as the initial solution of phase β. The hydrostatic pressure difference between the levels of the acid solution and of phase β was kept constant by continuous addition of solution to the acid bottle and removal of an adequate volume from phase β. Thus there were steady flows of hydrochloric acid and water from phase α through the membrane to phase β.

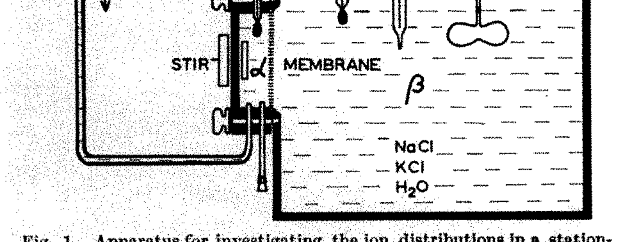

Fig. 1. Apparatus for investigating the ion distributions in a stationary-state system produced by the continuous supply of an acid and of water to the aqueous solutions of sodium chloride and potassium chloride

Against the flows of hydrochloric acid and water, Na^+ and K^+ migrated from phase β to phase α, until a time-independent non-equilibrium stationary-state distribution of all species in the system was attained. The time course towards this state was followed by measuring the potential difference between Ag/AgCl electrodes in the two chambers with a compensation potentiometer. Its decline to a constant value took 1·5–2 h. By taking successive samples from phase α, it was also found that within this time the concentrations of Na^+ and K^+ had increased and that of H^+ decreased to constant levels in this phase. The actual time for the attainment of the stationary state was taken as 3 h. The concentration of H^+ was titrated with sodium hydroxide, while those of Na^+ and K^+ were determined with a flame photometer.

The selectivity coefficient, r, for Na^+ and K^+ between the two phases was calculated as follows:

$$r = [Na^+]_\beta \cdot [K^+]_\alpha / [Na^+]_\alpha \cdot [K^+]_\beta$$

The flow rates of hydrochloric acid and water were changed in different experiments by changing the normality of the hydrochloric acid and the hydrostatic pressure difference between the levels of the acid solution and phase β. Since the normality and volume of acid solution lost in a given time were known, the rates of flow of hydrochloric acid and water through the membrane could be calculated.

Table 1 shows the stationary-state ion distributions as a function of various flow rates of hydrochloric acid and water. The experiments Nos. 3 and 10 represent extreme cases. In experiment No. 3, hydrochloric acid of high normality was supplied to phase α at low hydrostatic pressure, with the result that the distribution of other ions is determined chiefly by the diffusion effect of hydrochloric acid. This experiment resembles those of Teorell[3]. In this system the diffusion potential, arising from the low mobility of Cl^- in relation to that of H^+, leads to the accumulation of Na^+ and K^+ in phase α. However, the selectivity coefficient is low, that is, the distributions of Na^+ and K^+ are equally influenced. On the other hand, in experiment No. 10, hydrochloric acid of low normality is supplied to phase α at high hydrostatic pressure, with the result that the ion distributions are determined chiefly by the water flow. This experiment resembles those of Nims and Thurber[4]. This system increases K^+/Na^+ ratio in phase α, but the concentrations of both ions are lower in this phase than in phase β.

However, with simultaneous flows of hydrochloric acid and water, Na^+ and K^+ migrate continuously in the membrane pores with accelerated rates[5] against the reverse water flow, and since the mobility of K^+ is higher than that of Na^+, the final stationary-state concentration of K^+ may become even higher in phase α than in phase β,

Table 1. THE ION DISTRIBUTIONS IN A STATIONARY-STATE SYSTEM PRODUCED BY THE CONTINUOUS FLOWS OF AN ACID AND OF WATER TO THE AQUEOUS SOLUTION OF SODIUM CHLORIDE AND POTASSIUM CHLORIDE

Exp. No.	HCl solution (N)	Pressure (cm/H_2O)	Flow rates		Phase α (m.equiv./l.)			Ag/AgCl P.D. (mV)	r.
			HCl (m.equiv./min)	Water (ml./min)	(Na^+)	(K^+)	(H^+)		
1	1·6	4	0·049	0·030	175	7·4	140	36	1·27
2	3·1	4	0·074	0·024	206	8·8	195	48	1·28
3	6·4	4	0·140	0·022	272	12·0	360	71	1·33
4	1·6	30	0·85	0·53	17	1·7	1,250	123	3·00
5	3·1	18	0·85	0·27	80	5·2	1,550	130	1·95
6	6·2	12	0·96	0·15	120	8·4	1,990	165	2·10
7	6·1	16	1·22	0·20	99	7·3	2,400	173	2·20
8	6·2	18	1·36	0·22	93	7·2	2,400	180	2·32
9	3·2	30	1·67	0·52	21	2·4	2,200	156	3·43
10	1·9	59	2·22	1·17	8	0·8	1,700	143	3·08
11	3·2	50	2·46	0·77	10	1·2	2,500	163	3·60
12	6·2	30	3·10	0·51	41	4·9	3,900	201	3·58

In all the experiments phase β consisted of an aqueous solution of sodium chloride (150 m.equiv./l.) and of potassium chloride (5 m.equiv./l.). The Ag/AgCl electrode in phase α was negative.

while that of Na^+ remains lower in phase α than in phase β (exps. Nos. 6, 7 and 8).

Thus, this supply of hydrochloric acid and water leads to the transport of Na^+ and K^+ ions in opposite directions across the membrane; K^+ ion to phase α and Na^+ ion to phase β.

Physico-chemically this model deals with the problems of polycomponent processes. The recent progress of irreversible thermodynamics has facilitated the theoretical treatment of these systems. An attempt along these lines has been made in the following paper[6].

Regarding the possible biological usefulness of the present 'ion-pump' model, it is to be noted that the anions of an acid supplied to the system, which in the present model are Cl^- ions, are heterogeneous in living systems, including slow-moving polyanions. This is of interest, since the ability of the present model to accumulate K^+ depends on the relatively low mobility of Cl^- and not on the chemical interactions between the ions involved. It is true that natural anions can bind alkali ions, even with a certain selectivity, but as found so far, this binding seems to be too low to alone explain the distribution of these ions in living systems[7,8]. Concerning the other significant factor in the present experiments, that is, water movement, it is known that the cell membrane is relatively freely permeable to water and that the latter is apparently distributed between the cell and the extracellular fluid according to its chemical potential[8]. However, it is a fact that water, besides acids, is an end-product of oxidative metabolism. Thus there must exist places in which these substances are supplied to the system. Probably we may imagine that there are in the cell membrane different sites for the distribution of water and other uncharged substances on one hand, and for the 'ion-pumps' on the other.

Stationary Distribution of Ions across a Membrane in the System Sodium Chloride – Potassium Chloride – Hydrochloric Acid – Water

THE transport of ions across membranes has been treated theoretically by purely phenomenological methods, using the formalism of irreversible thermodynamics[1-3], or by a more 'kinetic' approach[4]. The former method gives a clear description of the transport processes, but in the general case it leads to equations containing unknown constants which depend on the properties of both the solutions and the membrane. Therefore the equations obtained are not applicable to numerical solutions of concrete problems.

However, if the membrane does not affect the properties of the solution, it is possible, in certain simple cases, to calculate approximately the ion distributions across the membrane, and to obtain relations between measurable quantities. It has already been suggested by Simo Salminen[5] that the system in which an acid and water are continuously supplied to the aqueous solution of sodium chloride and potassium chloride may be of interest as a model of biological ion transport systems. In the present work the ion distributions in this system have been studied theoretically with the aid of the concepts of irreversible thermodynamics.

Consider the isothermal system (Fig. 1) containing two homogeneous phases α and β, which are joined by a capillary k. The capillary diameter is large when compared with molecular dimensions, thus corresponding to the pores of the membrane used[5]. To the constant-volume part α a constant flow of aqueous solution of hydrochloric acid is supplied. The concentration of the hydrochloric acid is denoted by c_3^0. The compartment β contains an aqueous solution of sodium chloride and potassium chloride. The concentrations of these salts in the compartment β, c_1^β and c_2^β, respectively, are kept constant. Let us consider the system in a stationary state in which the concentrations of the components sodium chloride, potassium chloride and hydrochloric acid in compartment α are denoted by c_1^α, c_2^α and c_3^α respectively. It is assumed that the concentrations of the components sodium chloride, potassium chloride and hydrochloric acid in the capillary are continuous functions of the distance x, but are independent of the other spacial co-ordinates.

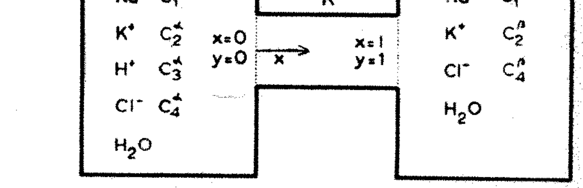

Fig. 1. Schematic representation of the system

The species Na^+, K^+, H^+, Cl^- and water are denoted by the suffixes 1, 2, . . . 5. In an isothermal system in quasi-mechanical equilibrium the flows of the species J_i may be presented in the form:

$$J_i = c_i(v_i - v_5) = \sum_{j=1}^{4} \alpha_{ij} X_j = -\sum_{j=1}^{4} \alpha_{ij}(\nabla \mu_j + z_j F \nabla \varphi) \quad (1)$$

where v_i is the velocity of the species i The conjugate force X_i is assumed to have been composed of two parts, the gradient of the 'chemical potential' μ_i and the gradient of the 'electrical potential' φ multiplied by the charge of the ion z_i and by the Faraday constant F The phenomenological coefficients α_{ij} are connected by the Onsager reciprocal relations

$$\alpha_{ij} = \alpha_{ji} \quad (2)$$

The electric current density is

$$I = F \sum_{i=1}^{4} z_i c_i v_i \quad (3)$$

The specific conductance is defined by the equation

$$I = \varkappa E \quad (4)$$

when

$$\nabla \mu_i = 0 \quad (5)$$

where E is the electric field strength

The mobilities of the ions and their transference numbers are defined by the equations

$$I t_i = z_i F J_i \quad (6)$$

$$(v_i - v_5) = \varepsilon_i u_i E \quad (7)$$

For cations $\varepsilon_i = +1$ and for anions $\varepsilon_i = -1$

From equations (1) to (7) we obtain

$$\varkappa = F \sum_{i=1}^{4} |z_i| \; c_i u_i = F^2 \sum_{i,j=1}^{4} z_i z_j \alpha_{ij} \quad (8)$$

$$u_i = c_i^{-1} F \varepsilon_i \sum_{j=1}^{4} z_j \alpha_{ij} \quad (9)$$

$$t_i = \frac{|z_i| c_i u_i}{\sum_{j=1}^{4} |z_j| c_j u_j} = \frac{z_i \sum_{j=1}^{4} z_j \alpha_{ij}}{\sum_{j,k=1}^{4} z_j z_k \alpha_{jk}} \quad (10)$$

In the present system $I = 0$, or according to (3)

$$\sum_{i=1}^{4} z_i J_i = 0 \quad (11)$$

As a consequence of (11) it is possible to use diffusion currents of the components sodium chloride, potassium chloride and hydrochloric acid instead of the diffusion currents of the corresponding ions

The chemical potentials of these compounds are

$$\mu_{\text{NaCl}} = \mu_1^4 = \mu_1 + \mu_4 \quad \mu_{\text{KCl}} = \mu_2^4 = \mu_2 + \mu_4$$
$$\mu_{\text{HCl}} = \mu_3^4 = \mu_3 + \mu_4 \quad (12)$$

For the diffusion current densities of the components the following phenomenological equations are valid

$$\begin{aligned} -J_{\text{NaCl}} &= -J_1^4 = a_{11}\nabla\mu_1^4 + a_{12}\nabla\mu_2^4 + a_{13}\nabla\mu_3^4 \\ -J_{\text{KCl}} &= -J_2^4 = a_{21}\nabla\mu_1^4 + a_{22}\nabla\mu_2^4 + a_{23}\nabla\mu_3^4 \quad (13) \\ -J_{\text{HCl}} &= -J_3^4 = a_{31}\nabla\mu_1^4 + a_{32}\nabla\mu_2^4 + a_{33}\nabla\mu_3^4 \end{aligned}$$

where the constants a_{ij} satisfy the Onsager reciprocal relations

$$a_{ij} = a_{ji} \quad (14)$$

According to equations (1), (2), (8), (10)–(13), the following relation between the phenomenological coefficients (2) and (14) is obtained

$$a_{ij} = \alpha_{ij} - t_i t_j \frac{\varkappa}{F^2} \quad (15)$$

The chemical potentials of the components μ_i^4 may be expressed by the equation

$$\mu_i^4 = \mu_i^4(T\,P, c_1\,c_2, c_3) = \mu_i^{4\circ}(T,P) + RT\ln c_i c_4 + 2RT\ln y_i^4 \quad (16)$$

where y_i^4 is the mean molar activity coefficient

Using the notation

$$\mu_{ij}^4 = \frac{\partial \mu_i^4}{\partial c_i^4} \quad (17)$$

from (13), (16) and (17), we obtain

$$\begin{aligned} -J_1^4 &= D_{11}\nabla c_1 + D_{12}\nabla c_2 + D_{13}\nabla c_3 \\ -J_2^4 &= D_{21}\nabla c_1 + D_{22}\nabla c_2 + D_{23}\nabla c_3 \quad (18) \\ -J_3^4 &= D_{31}\nabla c_1 + D_{32}\nabla c_2 + D_{33}\nabla c_3 \end{aligned}$$

where

$$D_{ij} = \sum_{l=1}^{3} a_{il}\mu_{lj}^4 = RT\sum_{l=1}^{3} \frac{a_{il}}{c_l}\left(\delta_{lj} + \frac{c_l}{c_4} + 2c_l \frac{\partial \ln y_l^4}{\partial c_j}\right) \quad (19)$$

δ_{lj} being the Kronecker symbol

If we introduce the following approximations

$$\alpha_{ij} = 0 \; (i \neq j) \quad (20)$$

$$\alpha_{ii} = \frac{c_i u_i^0}{F} = \frac{c_i \lambda_i^0}{F^2} \quad (21)$$

$$\frac{\partial \ln y_i}{\partial c_j} = 0 \quad (22)$$

where $\lambda_i^0 = F u_i^0$ and u_i^0 is the limiting ionic mobility. (8)–(10) (15), and (19)–(22) yield

$$D_{ij} = \frac{RT}{F^2} \lambda_i^0\left(\delta_{ij} - \frac{c_i}{\sum_{i=1}^{4} c_i \lambda_i^0} \; (\lambda_j^0 - \lambda_4^0)\right) \quad (23)$$

By solving the equations (18) for the concentration gradients we obtain

$$\begin{aligned} \frac{dc_1}{dx} &= -\frac{1}{D}(D_1^1 J_1^4 + D_2^1 J_2^4 + D_3^1 J_3^4) \\ \frac{dc_2}{dx} &= -\frac{1}{D}(D_1^2 J_1^4 + D_2^2 J_2^4 + D_3^2 J_3^4) \quad (24) \\ \frac{dc_3}{dx} &= -\frac{1}{D}(D_1^3 J_1^4 + D_2^3 J_2^4 + D_3^3 J_3^4) \end{aligned}$$

where the assumption that the concentrations c_i are functions of x alone has been taken into consideration In the equations (24) D is the determinant

$$D = |D_{ij}| \quad (25)$$

and D_i^j is the co-factor of the element D_{ij}

Since $c_4 = c_1 + c_2 + c_3$ we may write instead of the last equation of (24)

$$\frac{dc_4}{dx} = -\frac{1}{D}\left(\sum_{i=1}^{3} D_1^i J_1^4 + \sum_{i=1}^{3} D_2^i J_2^4 + \sum_{i=1}^{3} D_3^i J_2^4\right) \quad (26)$$

In the stationary state under consideration we have

$$v_1 = v_2 = 0 \quad (27)$$

From the equations (1) and (24)–(27) we obtain the system of differential equations

$$\begin{aligned} \frac{dc_1}{dx} &= c_1\left(A_1 + B_1\frac{c_1}{c_4} + B_2\frac{c_2}{c_4} + E\frac{1}{c_4}\right) \\ \frac{dc_2}{dx} &= c_2\left(A_2 + B_1\frac{c_1}{c_4} + B_2\frac{c_2}{c_4} + E\frac{1}{c_4}\right) \quad (28) \\ \frac{dc_4}{dx} &= c_4\left(\frac{v_5}{D_{33}} - B_1\frac{c_1}{c_4} - B_2\frac{c_2}{c_4} - \frac{c_3 v_3}{B_{33}^0}\right) \end{aligned}$$

where

$$A_i = v_5\left(\frac{2}{D_{ii}^0} - \frac{1}{D_{33}^0}\right), \quad B_i = v_5\left(\frac{1}{D_{33}^0} - \frac{1}{D_{ii}^0}\right) \quad (i = 1,2) \quad (29)$$

$$E = c_3 v_3 \frac{F^2}{2RT}\left(\frac{1}{\lambda_3^0} - \frac{1}{\lambda_4^0}\right), \quad D_{ii}^0 = \frac{2RT}{F^2}\left(\frac{1}{\lambda_i^0} + \frac{1}{\lambda_4^0}\right) \quad (i = 1,2\,3)$$

In the simplified case, when $c_3 = 0$, it follows from the equations (28) and (29) that

$$D^0_{11}\mathrm{d}\ln c_1c_4 = 2v_5\mathrm{d}x = D^0_{22}\mathrm{d}\ln c_2c_4 \tag{30}$$

Integration from $x = 0$ to $x = l$ yields

$$D^0_{11}\ln\frac{c_1^\beta c_4^\beta}{c_1^\alpha c_4^\alpha} = D^0_{22}\ln\frac{c_2^\beta c_\beta^4}{c_2^\alpha c_4^\alpha} \tag{31}$$

Nims and Thurber[6] have studied ion distributions across a membrane in a sodium chloride–potassium chloride–water system and Nims[7] has derived an equation for the distribution of Na+ and K+ ions in this case. The equation (31) is the same as the equation (35) in Nims's paper[7], if the activity coefficients are left out of consideration.

Returning to the quaternary system, the first two equations (28) yield

$$\frac{\mathrm{d}\ln\frac{c_1}{c_2}}{\mathrm{d}x} = 2\left(\frac{1}{D^0_{11}} - \frac{1}{D^0_{22}}\right)v_5 \tag{32}$$

Integrating (32) from $x = 0$ to $x = l$ we obtain

$$\ln r = \ln\frac{\frac{c_1^\beta}{c_2^\beta}}{\frac{c_1^\alpha}{c_2^\alpha}} = 2\left(\frac{1}{D^0_{11}} - \frac{1}{D^0_{22}}\right)v_5 l \tag{33}$$

From the equation (33) it will be seen that the selectivity coefficient[5], r, depends on the velocity of water v_5 and on the length of the capillary l, but not, with the approximations (20)–(22), on the concentration of hydrochloric acid.

The coefficients (29) in the equations (28) may be calculated from the known mobilities u_i^0, but the velocities v_3 and v_5 are not experimentally known quantities.

In a stationary state, the amount of hydrochloric acid supplied to the part α equals the amount escaping through the capillary k, and we may write

$$c_3v_3 = c_3^0v_5 \tag{34}$$

A new variable is defined as

$$y = \frac{x}{l} \tag{35}$$

Substitution of equations (33)–(35) and the values[8] of the ionic equivalent conductivities at 25° C λ_i^0 (cm² ohm⁻¹ equiv.⁻¹) $\lambda_1^0 = 50.10$, $\lambda_2^0 = 73.50$, $\lambda_3^0 = 349.8$, $\lambda_4^0 = 76.35$ in the equation (28) yields

$$\begin{aligned}
\frac{\mathrm{d}c_1}{\mathrm{d}y} &= -\ln r\, c_1\left(3.943 - 1.345\frac{c_1}{c_4} - 0.845\frac{c_2}{c_4} - 0.803\frac{c_3^0}{c_4}\right)\\
\frac{\mathrm{d}c_2}{\mathrm{d}y} &= -\ln r\, c_2\left(2.943 - 1.345\frac{c_1}{c_4} + 0.845\frac{c_2}{c_4} - 1.253\frac{c_3^0}{c_4}\right) \qquad (36)\\
\frac{\mathrm{d}c_4}{\mathrm{d}y} &= -\ln r\, c_4\left(1.253 + 1.345\frac{c_1}{c_4} + 0.845\frac{c_2}{c_4} - 1.253\frac{c_3^0}{c_4}\right).
\end{aligned}$$

The system of differential equations (36) is not solvable in closed form. The equations can be integrated numerically, however, when the values of $\ln r$, c_3^0, and of the c_i's on one of the boundaries are known. In the experiments[5], the boundary conditions to the right of the membrane were

$$c_1^\beta = 150 \text{ mC},\ c_2^\beta = 5 \text{ mC},\ c_4^\beta = 155 \text{ mC}$$

The concentration of hydrochloric acid c_3^0 and the rate of water flow were varied. The distribution ratio r is, in turn, a function of the water flow, according to equation (33). The numerical integration of the differential equation system (36) was made by the Runge–Kutta method, using an Elliot 803 electronic digital computor. The results for the values $r = 1.1$, 1.3, 2.0, 3.0 and $c_3^0 = 1.6$, 3.0, 6.0 mol./l. are given graphically in Fig. 2, where the stationary-state concentrations of Na+, K+ and Cl− ions in the capillary are presented as functions of the length of the capillary.

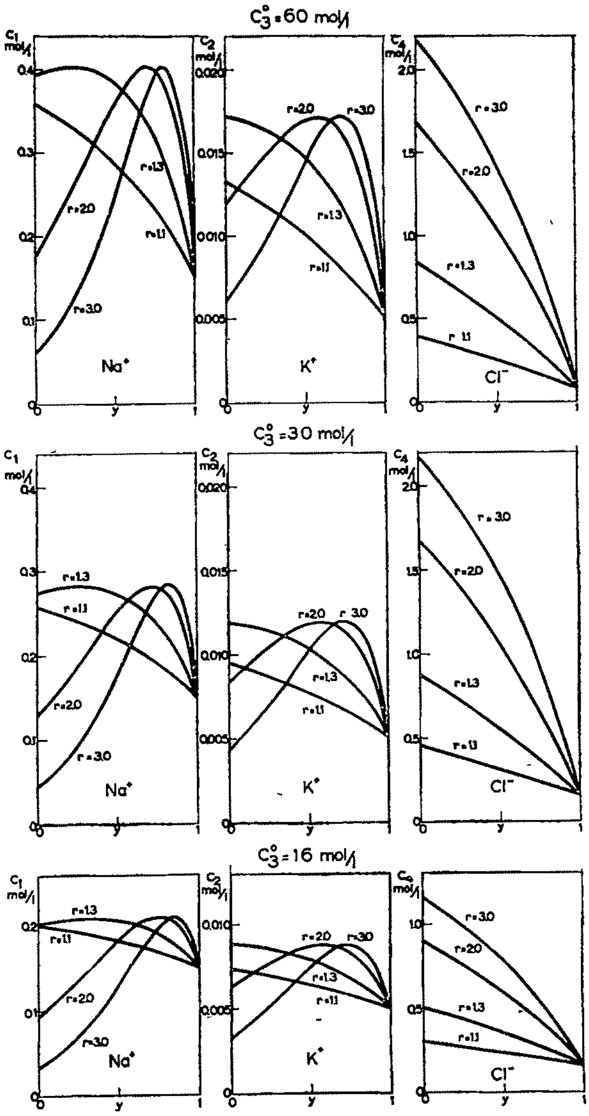

Fig. 2. Stationary state distribution of Na+, K+ and Cl− ions in the capillary

The values at the left end of the capillary represent the calculated ion concentrations in compartment α. If we take into consideration the rather rough approximations (20)–(22), the agreement between the present theoretical and previous experimental[5] results is fairly good.

The selectivity coefficient r depends, as was previously pointed out, only on the rate of water flow. The relation between the selectivity coefficient and the water flow depends, according to (33), on the length and effective cross-section of the capillary and is thus a property of the membrane and usually unknown. On the other hand, the ratios c^α/c_1^β and c_2^α/c_2^β depend on the concentration of hydrochloric acid as well.

From Fig. 2 and from the equations (36) it may be seen that the concentration maxima of Na+ and K+ inside the capillary are independent of the ratio r, that is, of the water flow. The maxima increase with increasing concentration of hydrochloric acid. They are relatively greater and lie more to the left for K+ than for Na+.

As the water flow rate is increased, the stationary concentrations of Na+ and K+ in compartment α at first increase and reach their maxima, Na+ at a lower rate of flow than K+ With a further increase of the water flow rate then concentrations again decrease

Furthermore, it may be seen from Fig 2 that at certain water flow rates and hydrochloric acid concentrations a stationary state may be reached in which the K+ concentrations in compartment α are higher and the Na+ concentrations lower than the corresponding concentrations in compartment β, as has also been verified experimentally[5] Thus the present system acts as an ion 'pump' which transports the Na+ and K+ ions in opposite directions across the membrane against their concentration gradients Consequently, this system is a rational demonstration of a type of ion transport which in biology has often been termed active transport of ions

RECOVERY EFFECTS OF HOMOLOGOUS TESTES DNA INJECTED INTO TOTAL-BODY IRRADIATED (600 R) INFANTILE RATS AND MICE

By Miss N. SAVKOVIĆ

'Boris Kidrič' Institute of Nuclear Sciences, Belgrade

THE problem of discovering remedies for post-irradiation treatment of irradiated organisms is of importance The therapeutical results are theoretically important because the solution of this problem would render more comprehensive the mechanism of lesion formation caused by irradiation From the practical point of view, the problem is important because appropriate therapeutic remedies could be used in clinical radiotherapy

It has been shown that in different animals the effects of lethal radiation can be modified by certain treatments applied after irradiation Some results show that irradiated animals can recover after being treated with the bone marrow[1,2] and homogenate spleen[3] Cole *et al*[4] found that extracts of blood-forming tissues are therapeutically efficient They assume that the humoral factor is identical with deoxyribonucleoproteins

Kanazir *et al* assume that damage and mortality of irradiated organisms are due to damage of the genetic system In view of the fact that the genes are composed of DNA molecules, the primary initial lesions induced by radiation can cause damage of the DNA and RNA structure[5]

It is also assumed that the recovery process and the survival of the radiation syndrome after irradiation depends on the metabolism structure and the biological function of nucleic acids It was on this basis that I investigated the effect of DNA on the irradiated organism These experiments have given positive results The work of D Kanazir[6–8] has shown that DNA and RNA administered after exposure to lethal X-irradiation protects adult irradiated organisms Spleen and liver DNA have proved to be most efficient Histological analyses of the spleen, bone marrow[9], digestive tract, liver[10] and the adrenal gland[11] made by D Kanazir *et al* showed that damage to lethally irradiated and DNA treated animals is less than in the controls Other authors have also shown that nucleic acids administered after lethal irradiation increase the survival percentage of rats, mice and bacteria[12–14]

The toxic effect of these natural products after short treatment is minimum

The literature, however, does not provide any data on the restorative effect of DNA on animals irradiated in the infant period

I have investigated whether homologous testes DNA in sexually mature rats and mice exerts influence on the radiation syndrome and the survival of rats and mice irradiated during the infant period

White male Wistar rats and *C57Bl* male mice 8 and 17 days old were used in the experiments The animals were exposed to an X-ray dose of 600 r A Siemens Stabilipan apparatus was used under the following conditions 200 kV , 14 m amp , aluminium 3, 150 r /min at a target distance of 46 cm The animals were irradiated in wooden boxes and were then returned to their unirradiated mothers

Immediately after irradiation the animals were treated with DNA extracted from the testes of sexually mature animals (2 5 months old) The extraction was performed by the Zamenhof method[15] Each irradiated male animal was administered the quantity of DNA extracted from one pair of testes It was injected intraperitoneally in fractions for 48 h The first fraction was injected immediately after irradiation

Fig 1 shows the results of the survival of rats irradiated at early ages

The amount applied per rat varied from 0 940 to 1,300 mg

Rats, 8 days old, irradiated and treated with DNA (after irradiation) showed a 75 per cent (±7 0) survival, while only 8 per cent (±2 3) of untreated controls survived

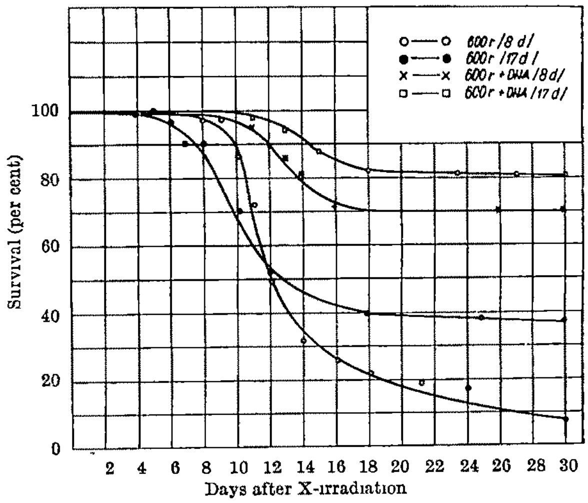

Fig 1

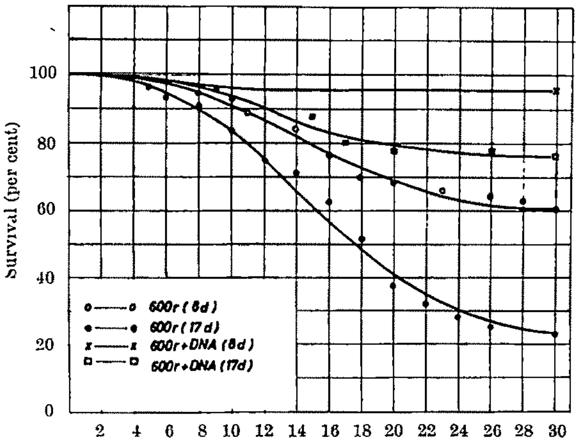

Fig 2

irradiation, the survival effect was observed in 82 treated animals and 100 controls This indicates that DNA reduces the radiation effect by a factor of 8 7 ($P < 0\ 001$)

Rats, 17 days old, irradiated and treated with DNA showed a 70 per cent (± 3 4) survival, while the controls showed 37 per cent (± 3 5), the effect was observed in 79 treated animals and 100 controls DNA reduces the effect by a factor of 2 ($P < 0\ 001$)

Fig 2 shows the restorative effect of testes DNA on the survival of mice irradiated in the infantile period

The amount of DNA was 1,500 mg

The results obtained show that DNA injected into mice irradiated at the infant stage also conditions a high degree of survival

(1) In irradiated-treated 8-day-old mice the survival was 95 (± 4 per cent) and in controls it was 60 (± 7 3) per cent, the number of animals was 40 and 100, respectively The results are statistically significant ($P < 0\ 01$)

(2) Mice which were 17 days old at the moment of irradiation and were treated with DNA after irradiation showed a 76 (± 3) per cent survival Controls of the same age showed a 23 (± 9 0) per cent survival, 58 and 80 animals, respectively, were observed These results are also statistically very significant ($P < 0\ 001$)

These results show that the administration of testes DNA increases the percentage of survival in both rats and mice in the infantile period These results are, therefore, more reliable because these two types of animals do not react in the same way Namely, 8-day-old rats are more sensitive to radiation and their percentage of survival is lower, whereas 17-day-old rats are more resistant and their percentage of survival is higher The behaviour of mice, however, is quite different 17-day-old mice are more sensitive than 8-day-old ones We also observed this phenomenon in our experiments with mice to which we gave chemical protectors[16]

Quastler also found that 1-week-old mice are more resistant to radiation than adult animals According to Ingbaru the sensitivity increases in the course of the first weeks of life, reaching the maximum one month after birth, and slightly decreasing in the following weeks[17]

CHEMOSTATIC REGULATION OF APPETITE IN SHEEP

By J. M. HOLDER

Agricultural Research Station, Wollongbar, New South Wales

THE presence of hypothalamic centres associated with regulation of voluntary intake of food has been clearly demonstrated in many species[1] There is still considerable conjecture as to the mechanisms by which the so-called 'appetite' (lateral hypothalamic) and 'satiety' (ventro-medial hypothalamic) centres are, in the short term, stimulated or depressed Various suggestions have included the influence of specific dynamic action of food eaten[2], of osmotic effects of the diet[3], of sensory impulses from the digestive tract[4], and the concentration of certain metabolites in the blood passing through the brain centres[5,6]

Although evidence available[5,7,8] suggests an important role for glucose utilization by hypothalamic centres in monogastric appetite control, there is little to suggest that alterations in the level of this metabolite will be of importance in ruminants Blood glucose-levels in normal cattle and sheep are remarkably constant with little fluctuation associated with feeding[9] Manning *et al* [10] produced significant increases in the blood sugar of adult ewes by injection of 200–1,000 ml 50 per cent glucose solution in two equally divided doses, 60 min apart However, in the 60 min following the second injection, the appetite of their ewes was not affected when compared with controls They suggest that blood volatile fatty acids would be more likely to influence hypothalamic centres in the sheep because levels of blood acetate, particularly, rise following feeding and then gradually fall until the next meal[11] In support of this hypothesis, Dowden and Jacobson[12], with continuous infusion over 8 h of acetic acid, sodium acetate or propionic acid, produced highly significant depression in voluntary intake of lucerne hay by monozygous twin heifers during the infusion period Appetite apparently returned shortly after the infusion ceased

As part of an investigation of factors affecting the voluntary intake of food by ruminants, the role of circulating volatile fatty acids and of glucose in appetite regulation in the sheep has been assessed Merino ewes and wethers were trained to eat in 2 h the food offered to them each day Intravenous infusion of test solutions usually commenced at least 2 h before the time the sheep would normally have been fed To eliminate variation between animals in daily food intake, each sheep served as its own control, in receiving a continuous infusion of normal saline on the day prior to or succeeding the test infusion

Table 1 EFFECT OF INTRAVENOUS INFUSIONS OF GLUCOSE OR SODIUM ACETATE ON APPETITE OF SHEEP

Series	Sheep	Weight (kg)	Infusion solution	Duration infusion (min)	Feed Offered (g)	Feed Consumed (g)	Maximum plasma-level of metabolite achieved Glucose (mg/100 ml)	Maximum plasma-level of metabolite achieved Volatile fatty acids (m mol/l)
1	1♀	40 4	N saline	210	600 lucerne + 200 oats at 155 min	All by 200 min	89	0 81
			40% acetate	210		All by 180 min	60	2 22
	2♀	31 3	N saline	210	600 lucerne at 155 min	576 by 270 min	65	0 88
			40% acetate	210		583 by 270 min	64	2 44
2	3☿	43 4	N saline	210	800 lucerne at 143 min	550 by 263 min	62	—
			25% glucose	210	,	790 by 263 min	85	—
3	4☿	35 4	N saline	210	800 lucerne at 155 min	790 by 275 min	69	—
			40% glucose	210	As above at 150 min	All by 270 min	126	—
4	4☿	39 0	N saline	480	1,500 lucerne at 0 min	1,280 by 480 min	—	1 62
			40% acetate	480	,	810 by 480 min	—	1 63
			N saline	480	,	940 by 480 min	—	Not recorded
5	5☿	39 0	40% acetate	480	1,500 lucerne at 0 min	640 by 480 min	—	1 89
			N saline	480	,	630 by 480 min	—	1 45
			40% acetate	480	,,	960 by 480 min	—	Not recorded

All infusions were given at the rate of 1/3 ml per min by a slow injection apparatus (C F Palmer Ltd , London) The effect on appetite of infusions of 25 or 40 per cent glucose or 40 per cent sodium acetate solutions over 210-min periods is given in Table 1

On no occasion was there any apparent effect on voluntary intake caused by infusion of the glucose solutions Blood glucose-levels did not reach those achieved by Manning *et al* , but the continuous infusion of 40 per cent glucose produced venous levels approximately twice the normal values during most of the feeding period Sodium acetate infusions over 210 min did not produce a fall in intake despite blood volatile fatty acid levels almost three times the normal range This result is quite the opposite to that obtained by Dowden and Jacobson with their heifers, despite the relatively far greater quantity of acetate infused into the sheep

There was a possibility that the experimental sheep in being trained to expect their feed at a fixed time each day may have had the action of eating sufficiently 'imprinted' to eat despite the raised levels of metabolite To examine this possibility sheep were offered lucerne chaff *ad libitum* Weighing of residues and refeeding occurred daily at 0900 h An infusion of 40 per cent sodium acetate commenced at feeding and continuing for 8 h had no apparent effect on voluntary intake over this period, in one series (No 5, Table 1) In a second series (No 4) there was a fall in intake over the acetate infusion period, compared with the saline infusion the previous day However, a check saline infusion on the day following the acetate, produced a similar fall in intake, suggesting that the appetite depression was provoked by factors other than the acetate solution

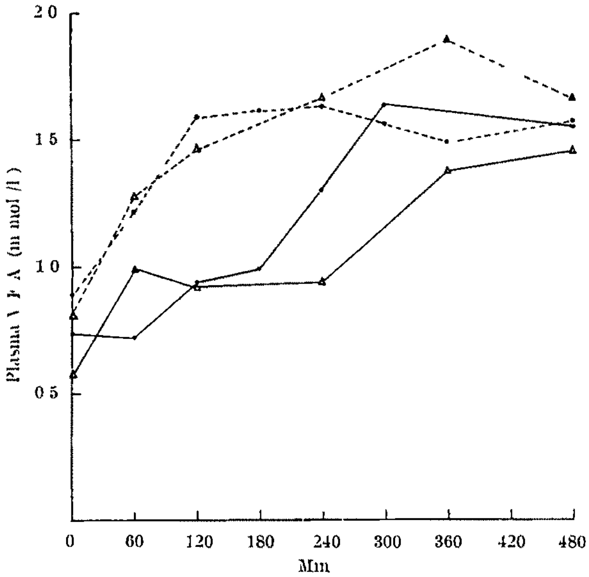

Fig 1 Plasma volatile fatty acid levels in sheep during infusion of acetate or N saline solution — ● —, Sheep 4, saline, – – ● – – sheep 4, 40 per cent acetate —△—, sheep 5, saline, – – △ – – sheep 5, 40 per cent acetate

Two points should be noted here The high blood volatile fatty acid levels achieved in series 1, following acetate infusion, relative to those in series 4 and 5 are presumably due to the 'explosive' nature of volatile fatty acid production in sheep accustomed to eating quite large quantities of feed over a short period Secondly, maximum blood volatile fatty acid levels achieved by acetate infusion in series 4 and 5 are not greatly different from those produced during saline infusion However, it was demonstrated (Fig 1) that acetate infusion achieved high levels within 1 h of the infusion commencing Similar levels were not achieved until 4–6 h after saline infusion commenced These levels were presumably the effect of feed eaten by that time

The reason for the disparity between present results with acetate and those of previous workers[12] is not clear A species difference does not seem likely It may be significant that an appreciable depression of food intake was also recorded by these workers with the only other acid metabolite, propionic acid, infused in comparable quantities This metabolite is not normally present above trace-levels in the peripheral circulation, as it is converted to glucose in the liver after absorption from the rumen and transfer via the portal vein[13] Yet a larger infusion of glucose had no effect on appetite This suggests that an unphysiological level of anion in the peripheral system may have inhibited appetite in the cattle, although no data on blood levels achieved were presented

The results indicate that neither blood glucose level nor blood acetate level is a major factor in regulating appetite in the sheep

This work was conducted while I held a Commonwealth Post Graduate Scholarship in the School of Rural Science University of New England, Armidale

ACTION CURRENT AS A POSSIBLE SOURCE FOR THE NEGATIVE AFTER-POTENTIAL OF STRIATED MUSCLE

By Prof. HOWARD JENERICK

Department of Physiology, Emroy University, Atlanta 22, Georgia

INSUFFICIENT evidence is at present available concerning the genesis of the negative after-potential which follows the spike response in striated muscle While it is fairly certain from measurements of the time-course, that the after-potential represents a passive electrotonic decay[1], the processes which determine its initial magnitude are poorly understood Recently, analytical methods were developed for computing the trans-membrane ionic current which accompanies the propagated spike potential in the frog sartorius muscle fibre[2] It was felt that such results might aid in elucidating the after-potential, and the following is a report of my findings.

The propagated response is associated with a massive inflow of current which lasts less than 0 5 msec and is followed by a smaller, outward current of several msec duration In the work recorded here, I measured the net uptake and loss of trans-membrane ionic charge caused by the inflow and outflow of the action current (Fig 1) Since charge is equal to the product of current × time ($q = \int I dt$), these measurements were made by planimetric integration of the area under the curve of the trans-membrane ionic current plotted against time The areas indicated in Fig 1 correspond to a net uptake, q_i, of 6 4 p moles/cm^2 and a net loss, q_0, of 4 5 p moles/cm^2, leaving an unbalanced intracellular charge ($\delta q = q_i - q_0$) of 1 9 p moles/cm^2 Note that the outward current has declined virtually to zero near the end of the spike response (at 4–4 5 msec in Fig 1) Hence, the rapid outflow of charge ended approximately at the beginning of the negative after-potential V_n, before a complete exchange occurred

Sample calculations showed that if the charge, represented by δq, is distributed on the membrane capacitance C_m, a potential is generated which is of proper sign and approximate magnitude to account for the initial value of the negative after-potential, namely, $V_n \sim \delta g/C_m$ (Although our methods are not sensitive enough to detect any ionic current during the decay of the after-potential, such current must occur to drain off the internal charge)

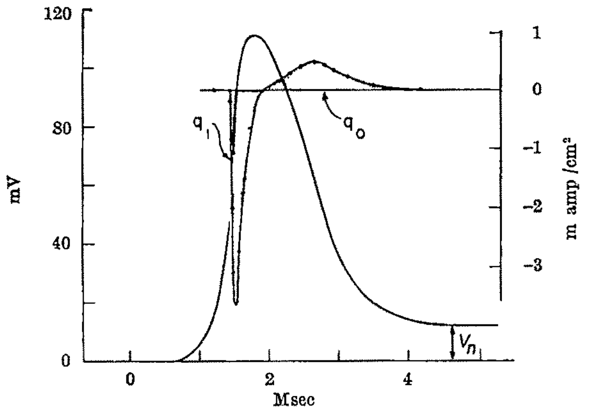

Fig 1 A propagated trans-membrane spike-potential traced from the original record and the computed ionic current are aligned in time for comparison The inward current (plotted downward) reaches its peak value before the maximum spike height is reached and reverses shortly thereafter Note that the outward current subsides markedly during the terminal phase of the spike potential and approaches the base-line before the initial value of the after-potential is reached (V_n) Current magnitudes in m amp/cm^2 of membrane are based on an assumed value of 5 μF/cm^2 for the membrane capacitance The areas under the inward and outward current plots correspond to a charge uptake q_i, of 6 4 p moles/cm^2 and a loss, q_0, of 4 5 p moles/cm^2

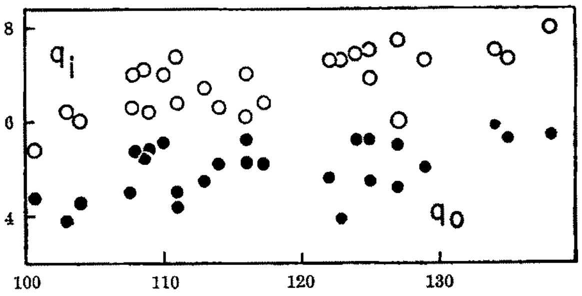

Fig 2 Effect of varying Na$^+$ and K$^+$ concentrations on the transient uptake (○) and loss (●) of intracellular charge (p.moles/cm^2 of membrane) during the response as a function of the spike-potential

A systematic study of the magnitudes of q_i, q_0, and particularly of δq, was made to determine whether or not the foregoing relationship between charge accumulation and the initial value of the after-potential was an accidental one In the initial series of experiments, I used Ringer's fluid with the following variations sodium chloride, 35–110 mM, potassium chloride, 1–5 mM, pH 7 2–7 4 No consistent increase or decrease, within the limits of error in q_i, q_0 or δq as related to the spike height (V_s), was observed (Fig 2) However, my methods for the determination of charge may have suffered from a 5–10 per cent error introduced by the graphical analysis, and if any changes did occur, they were possibly masked by these errors There was some dependence of q_i and q_0 on the spike potential magnitude, based on computations of 26 separate responses (Fig 2) Note the vertical separation of the data which indicates the magnitude of δq This gradually decreases with the spike potential, as does the after-potential However, these changes are too small, perhaps, to be convincing When sodium chloride in a standard Ringer fluid was replaced by sodium nitrate, the spike potential magnitude and q_i were unaffected, whereas the net charge loss, q_0, decreased by 20–30 per cent during the downstroke of the spike Since the initial charge gain, q_i, was unchanged, $\delta q = (q_i - q_0)$ was necessarily raised Simultaneously, the negative after-potential was increased by ~ 25 per cent in the nitrate–Ringer This gave encouraging evidence for the postulated role of δq in the genesis of the after-potential

The relationship of charge and the after-potential was further tested by using the pH of the Ringer fluid as an experimental variable, since it has been observed in our laboratory that acidic fluids (pH 5–6) markedly increased and basic fluids (pH 9–10) decreased the initial value of the negative after-potential in frog sartorius fibres While the charge uptake, q_i, remained unaffected by solution pH, the charge loss, q_0, was significantly diminished in acidic fluids and enhanced in basic fluids Under these conditions the net accumulation (gain minus loss) at the beginning of the after-potential varied between 4 1 and 'zero' pmoles/cm^2, while the associated negative after-potential varied from 50 to $\frac{1}{2}$ mV respectively (Fig 3) (Fig 3 includes the data shown in Fig 2) The solid line in Fig 3 represents the predicted relationship $V_n = \delta q/C$, between δq, the initial value of the negative after-potential V_n, and the membrane capacitance C, chosen at 5 μF/cm². The dashed lines are least-squares regression lines of δq on V_n and vice versa. Although the hypothesis requires that δq be the independent variable, δq values are subject to a greater measurement error and have a greater variance than V_n. This in turn causes a clockwise rotation of the regression line of V_n on δq and tends to present a misleading picture of the relationship. In the circumstance, both regression lines were calculated and indicate a correlation coefficient, $r = 0.86$. All data for δq in Fig. 3 lie to the right of the predicted locus for capacitor charging. They suggest that a constant 'excess' charge ($= \delta q - V_n/C$) of 0.7–0.8 p moles/cm² is temporarily accumulated (regression of δq on V_n), or that the excess is a constant percentage ($\sim$ 40 per cent) of the total charge accumulation (regression of V_n on δq). While we cannot choose between these possibilities on the basis of the experimental evidence, it seems permissible to conjecture, in any event, that the 'excess' charge is unavailable for capacitor charging by virtue of (1) a transient interaction with ionizable materials in the membrane or cytoplasm, and/or (2) a participation in excitation-contraction coupling. In the latter connexion, the increase of δq and the excess charge by nitrate–Ringer fluid is highly suggestive and warrants further investigation.

As described in the previous communication, transmembrane current magnitudes are obtained from an analysis of the phase-plane record of the spike-potential by means of the cable equation. This results in determinations of the ratio, I/C (ionic current/membrane capacitance) at any selected point on the recorded response. In this report, these ratios were converted into units of current/cm² by assumption of a definite value (5 μF/cm²) for the membrane capacitance. It must be stressed that the capacitance enters Fig. 3 only as a scale factor for the abscissa and that its actual value cannot change the observed relationship between the predicted locus and δq, that is, since $V_n = \delta q/C$ and $\delta q = \int I dt$, therefore, $V_n = \int (I/C) dt$. The right-hand member of this equality is obtained directly by the graphical integration of the original calculations in (I/C) and is therefore independent of the actual value of the membrane capacitance (provided C does not change during the response). In addition, the analysis provides separately for the capacitative current during the response. Hence, δq is independent of the 'normal' movement of charge on the capacitance and represents an additional source serving to affect the capacitor potential.

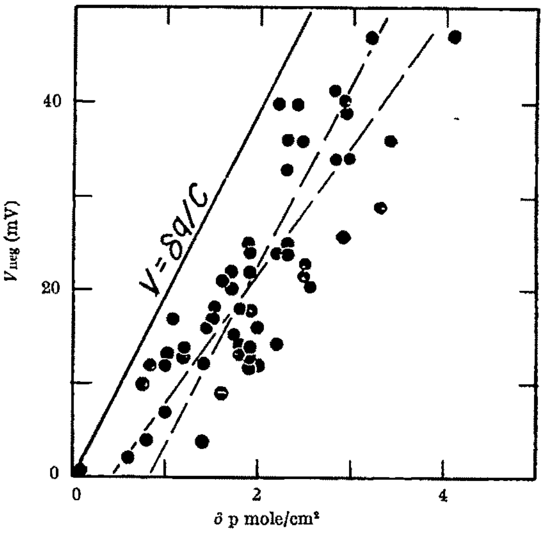

Fig. 3. The initial value of the negative after-potential (V_n) from 52 separate responses plotted as a function of the net accumulation of cationic charge, δq, during the spike potential. The solid line represents a predicted relation between the accumulated charge and the voltage on the membrane capacitance. The dashed lines are calculated least-squares regression lines.

The method described here does not reveal the mechanism by which the outflow of membrane ionic current is terminated before a complete exchange of cationic charge is effected. Since the amount of initial charge uptake, q_i, is fairly constant under a variety of conditions, including pH, it appears that the main determinant of the magnitude of the net charge accumulation, δq, is the degree to which the charge outflow q_0 can equalize q_i.

DEVELOPMENT OF CHLOROPLASTS AND THE SYNTHESIS OF PROTEINS IN LEAVES

By Dr. M. J. C. RHODES and Prof. E. W. YEMM

Department of Botany, University of Bristol

DURING normal vegetative growth of higher plants a rapid synthesis of proteins usually occurs in the young leaves. As the mesophyll cells expand and differentiate, chloroplasts are formed from proplastids and there is now much evidence that a major part of the leaf protein is structurally held in the chloroplasts, amounting in some species to 70–80 per cent of the total protein[1]. In an extension of earlier studies of the biosynthesis of proteins in barley seedlings[2–4], a more thorough investigation has recently been made of the development and metabolism of the first leaf. When the seedlings assimilate nitrogen, supplied as nitrate or ammonium salts under controlled conditions, most of it is transformed to protein in the shoot system. A preliminary investigation with isotopic nitrogen-15 indicated that the plastid fraction, separated by differential centrifugation, rapidly became labelled with nitrogen-15 and had an isotopic abundance more than twice that of the microsome fraction[5]. Particular attention has therefore been directed to the development of chloroplasts in the expanding leaf. The results so far obtained indicate that the plastids are active centres in which protein synthesis is closely associated with high levels of ribonucleic acids (RNA) in the young leaves. Moreover, the pronounced effects of light on the formation of proteins suggest that there is a close relation between protein metabolism and photosynthetic activities of the chloroplasts.

(1) *The changes of proteins and nucleic acids in developing leaves.* When barley seedlings are grown under controlled conditions in the light, the first leaf emerges from the coleoptile after 3 days. The leaf blade increases rapidly in size, its fresh weight and dry weight reaching fairly steady values after about eight days. Etiolated leaves, grown in continuous darkness, expand rather more slowly,

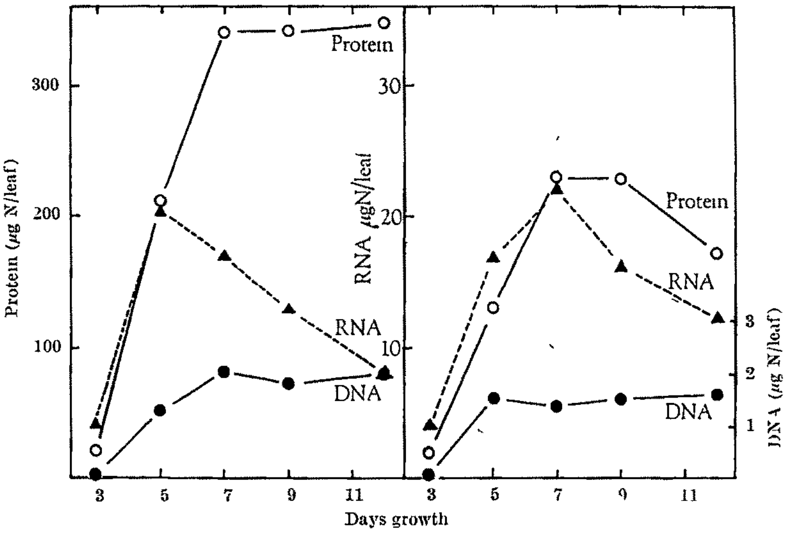

Fig. 1. Changes of proteins, RNA and DNA during the development of the first leaf of barley seedlings grown in the light (left) or in the dark (right). Samples of about 50 leaves were taken at each stage, and extracted exhaustively with ethanol, ice-cold 5 per cent perchloric acid and ether. The dried powder was subdivided for estimation of RNA (▲), DNA (●) and proteins (○).

but reach a similar maximum size after about nine days. Analytical data have been obtained to show the changes during development of some of the chief constituents of the leaves, including proteins and nucleic acids. For this purpose, nucleic acids were separated by a modification of the procedure of Schmidt and Thannhauser[6]. RNA was estimated after chromatographic purification of the nucleotides on an ion-exchange resin. Some of the results of an experiment, in which normal and etiolated leaves were compared, are illustrated in Fig. 1.

A rapid increase of RNA occurs during the first phase of leaf development. After reaching a maximum when the leaf is about half grown, the RNA content then falls to a level less than half that of the peak. The sequence and magnitude of these changes are very similar both in green and in etiolated leaves. Deoxyribonucleic acid (DNA) is present in much smaller amounts than RNA, its increase during leaf development follows a more regular course which roughly parallels that of leaf growth. The most rapid formation of proteins occurs during the early stages of development when RNA is maintained at a relatively high level. But substantially greater quantities of protein are formed in the light than in the dark, a difference which is further emphasized by the loss of protein from the etiolated leaves as they mature. One of our primary objectives in these experiments has been to relate the synthesis of proteins and other constituents to leaf development and, in particular, to changes in the structure and activity of the chloroplasts.

(2) *The composition and structure of plastids.* The fine structure and development of chloroplasts, including those of barley leaves, have been extensively studied by electron microscopy; several accounts have been given of the chief stages in the formation of the highly organized structure of the pigmented grana and colourless stroma[7-9]. On the other hand, much less is known of the composition of plastids and the way in which the main structural components, such as proteins, lipids and nucleic acids, change during differentiation. An attempt was made, therefore, to correlate changes in structure and composition by examining plastids separated from leaves at different stages of development. In this way it was also possible to estimate to what extent changes in the composition of the leaves were attributable to the differentiation of plastids.

Analyses of cell fractions, separated by differential centrifugation from young leaves, have shown consistently that a substantial part of the total RNA is sedimented with the plastids by relatively low centrifugal forces. Purification of the plastids, either by washing at the centrifuge or by sedimenting on a sucrose gradient, indicates that 20–30 per cent of the total RNA in the cell fractions of homogenates prepared from 4-day-old leaves is held in the plastids. High values of RNA in the plastid fraction have also been reported for young leaves of other species and for some algae[10,11]. However many tests with barley leaves have shown that the partition of RNA between the different cell fractions is strongly influenced by the conditions under which the separation is carried out. If preparations are made at pH 7·0, or above or are treated with deoxycholate a greater proportion of the RNA is recovered in the high-speed fractions and under extreme conditions most of it remains in the supernatant solution. It is probable that these changes result from the dispersion and leaching of nucleic acids from the plastids and other cell fractions; similar processes are now known to cause extensive losses of protein from chloroplasts during their separation in aqueous systems[12]. For comparative purposes, it is necessary to standardize the conditions of grinding and centrifugation as fully as possible. Table 1 summarizes an experiment in which the distribution of protein and nucleic acid was examined in cell fractions separated from normal and from etiolated leaves at different stages in their development.

Table 1. PROTEIN AND RNA IN CELL FRACTIONS OF NORMAL AND ETIOLATED LEAVES

(A) Protein (μgN/leaf)

Fractions	Light 6-day	Light 13-day	Dark 7-day	Dark 13-day
1 Plastids	56·5	49·0	31·2	16·7
2 Mitochondria and grana	17·3	15·4	15·0	11·4
3 Microsomes	13·4	5·7	16·5	9·4
Total (1–3)	87·2	70·1	62·7	37·5
Total/leaf	260	234	197	144
% Recovery	34	30	32	26

(B) RNA (μgN/leaf)

Fractions	Light 6-day	Light 13-day	Dark 7 day	Dark 13-day
1 Plastids	2·4	0·8	2·7	1·3
2 Mitochondria and grana	1·4	0·4	1·9	0·9
3 Microsomes	3·9	1·0	5·9	2·8
Total (1–3)	7·7	2·2	10·5	5·0
Total/leaf	21·4	7·0	21·0	13·0
% Recovery	36	32	50	38

Samples of 50 or more leaves were ground in cold 0·4 M sucrose buffered at pH 6·5 (5 ml./g tissue). Cell debris was removed by 'Terylene' gauze and centrifugation at 365g for 5 min. Fractions were then separated by centrifugation at 0° C as follows: (1) 5,000g for 10 min.; (2) 40,000g for 15 min.; (3) 75,000g for 90 min. Examination by light and electron microscopy indicated that the chief components of the fractions were (1) intact plastids (2–5μ); (2) mitochondria and grana (0·5–1μ); (3) microsomes (0·1–0·2μ).

Separate analyses of total protein and RNA in the leaves were made and the recovery in the fractions is shown.

It is evident from the results that the protein content in the plastid fraction of normal leaves is much greater than that of etiolated leaves; other cell fractions show relatively little difference between leaves grown in the light or in the dark. Having regard to the probable loss of proteins by leaching from separated plastids, it seems likely that the development of chloroplasts largely accounts for the greater formation of proteins in the light. On the other hand, the changes of RNA in the leaves appear to be fairly evenly distributed between the different cell fractions. The relatively high levels of RNA in the fractions from etiolated leaves reflect the comparatively slow loss of total RNA during the later stages of development in the dark. In general, the data indicate that the high levels of RNA in the young expanding leaves extend also to the plastids, in which a rapid formation of structural proteins is closely associated with the development and differentiation of chloroplasts in the light.

Electron microscopy has been used to investigate cellular differentiation in the leaves with the main object of correlating the changes in their composition with the development of plastids. For this purpose leaf tissues were fixed either in permanganate or osmic acid, embedded in 'Araldite' and sectioned in a Huxley–Cambridge microtome for examination in a Philips *EM* 200 electron microscope. The development of plastids in the light or in the dark diverges at an early stage in the expansion of the young leaf. Conspicuous primary lamellæ are rapidly formed in the light and they appear to arise either from small vesicles or from irregular extensions of the inner component of the plastid membrane. In 4-day seedlings after 24 h exposure to light the differentiation of grana can be seen; the older cells near the tip of the leaf contain many plastids with a few grana consisting of 3–6 disks closely associated with the primary lamellæ, while young cells at the base of the leaf have smaller plastids in which single grana disks are apparently present alongside the lamellæ. An illustration of cell and plastid structure at this early stage of development is given in Fig. 2. In comparable leaves grown in the dark, the lamellar structure of the plastids is much less conspicuous; commonly numerous small vesicles are seen which show some arrangement into layers, but as the plastid develops, a dense reticulate or vesicular structure, the prolamellar body, is formed in the central part. The fairly frequent occurrence of constricted and dumb-bell shaped plastids indicates that their division continues at this stage in both normal and etiolated leaves.

During the period of rapid leaf growth (days 4–7) in the light, the plastids increase in size and complexity, so that when the leaf blade is fully expanded all the mesophyll cells contain well-differentiated chloroplasts. This involves about a five- to ten-fold increase in volume, compared with typical plastids at day 4, and a major part of the structure is taken up by grana commonly consisting of 8–10 disks with irregular interconnecting lamellæ, similar to those already described[8]. A dominant feature of the development of the chloroplasts appears to be an extension and organization of specific lipoprotein membranes and this coincides with the increase of chlorophyll and proteins induced by light.

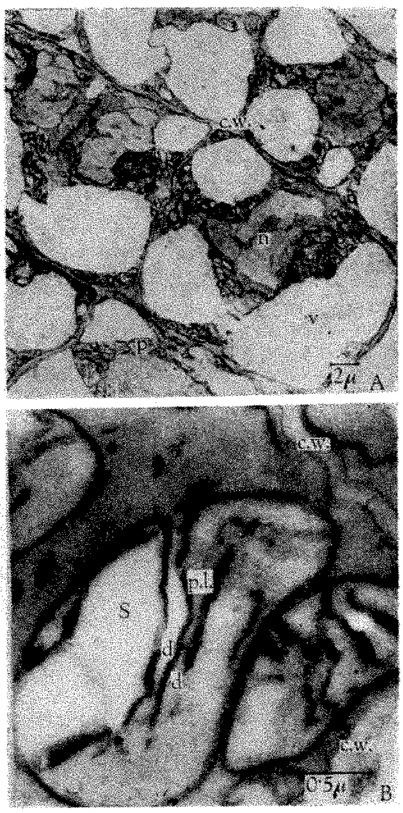

Fig. 2. Electron-micrographs of young cells from leaf of 4-day seedling after 24 h in the light (fixation in 2 per cent permanganate for 30 min at 0–4° C). *A*, vacuolating cells containing numerous plastids: plastids (*p*), cell-wall (*c.w.*), nucleus (*n*), vacuole (*v*); *B*, typical plastid at this stage showing large starch vacuole (*S*), primary lamellæ (*p.l.*) and rudimentary disk formation alongside (*d*)

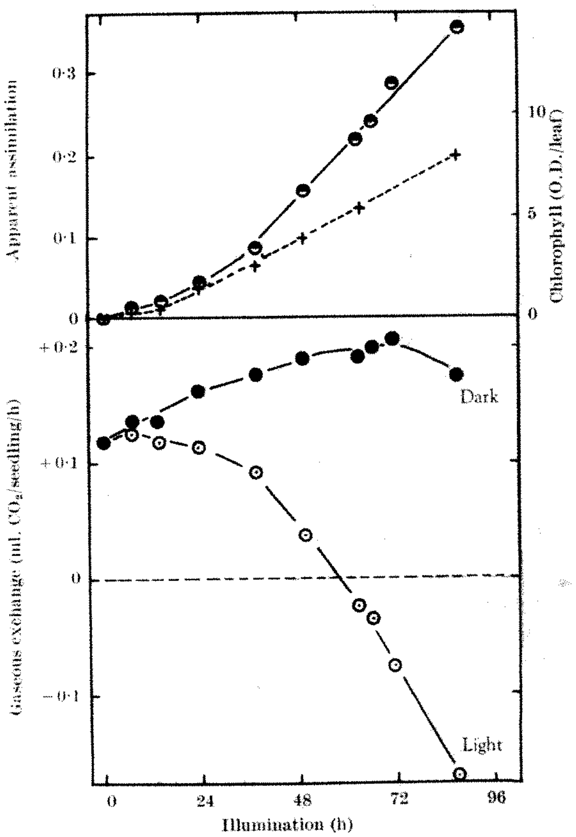

Fig. 3. The photosynthetic activity of young leaves. Measurements of carbon dioxide exchanges, shown in the lower part of the figure, were made on groups 40–50 seedlings in the dark (●) or in the light (⊙) (about 1,000 ft. candles) at 22·5° ± 1° C. Photosynthetic assimilation (◓) (estimated by difference between consecutive light and dark values) is shown here, together with chlorophyll content (+) measured spectrophotometrically at 665 mμ after extraction in ethanol

(3) *Photosynthetic activity of young leaves.* The formation of chlorophyll, probably at first by a photochemical conversion of protochlorophyll[13], occurs in the leaves within a few hours of exposure to light; the possibility is indicated that photosynthesis may play an important part in the metabolism of young leaves at an early stage in their development. However, it is well known that in some seedlings normal photosynthesis may lag behind the formation of chlorophyll[14]. In our experiments we have therefore obtained some further information on the photosynthetic activity of leaves grown under these conditions. The seedlings were germinated in glass chambers through which a steady stream of air could be passed and its carbon dioxide content monitored by means of an infra-red gas analyser. Measurements were made over short periods (30–60 min) alternating in the dark and in the light, and thus provided a sensitive method for detecting the effects of illumination on the carbon dioxide exchanges of the seedlings. The results of one of the experiments, in which estimates of the chlorophyll content of the seedlings were also made, are shown in Fig. 3.

An appreciable effect of light on carbon dioxide production was found consistently after illumination for 4–6 h of 3–4-day-old seedlings. The effect increased fairly steadily so that a compensation point between respiration and assimilation was reached after about 60 h. The rise of apparent assimilation in light followed a course similar to that of chlorophyll content, but there was evidence of an increase in the efficiency of the pigment system, since the ratio of assimilation rate to chlorophyll content rose from a value of 0·25 after 12 h to 0·36 after 80 h.

It is uncertain to what extent these results can be attributed simply to the photosynthetic assimilation of carbon dioxide. There is now evidence that respiratory and photosynthetic processes may interact at intermediate levels, such as the oxidation-reduction, phosphorylation or carbon substrate systems of the cell[15]. Some experiments, in which labelled carbon dioxide was used as a tracer, suggest that the chief products of assimilation during greening of etiolated leaves are amino-acids, such as aspartic and glutamic acids, together with malate; formation of sugar phosphates and full operation of the photosynthetic cycle seem to require longer exposure to light[16]. Despite these uncertainties, the data for developing barley leaves indicate that photosynthetic activity is an important feature of leaf metabolism during the phase of rapid differentiation of the chloroplasts. The rudimentary grana, rapidly formed in the plastids in the light, seem to be active at least in primary photochemical reactions and within about 48 h the coupling with normal carbon dioxide assimilation is effective.

(4) *Chloroplasts and the synthesis of proteins.* It is generally considered that light has an indirect effect on the synthesis of proteins in plants as a result of the formation of carbohydrates by carbon dioxide assimilation. There are, however, several lines of evidence that indicate a more direct coupling between photosynthesis and the metabolism of amino-acids and proteins in leaves. The early investigations of photosynthesis with $^{14}CO_2$ demonstrated that amino-acids such as alanine and aspartic acid are among the first compounds to become labelled[17], and this has been confirmed more recently with cell-free preparations of chloroplasts[18]. When ammonia is supplied to algal cells during the assimilation of $^{14}CO_2$, a major part of the radioactivity is recovered in amino-acids[19], rather than in sugars and sugar phosphates, while kinetic investigations strongly suggest that a relatively independent pool of amino-acids is maintained in the chloroplasts which could account for more than 60 per cent of the synthesis of proteins in the cells[20]. The action of ammonium salts as reversible uncouplers of photophosphorylation in the Hill reaction[21] and as inhibitors of carbon dioxide assimilation[22] may be important in relation to the photosynthesis of amino-acids. In leaves there is some evidence that intermediates of photosynthesis, rather than carbohydrates, are diverted to the synthesis of proteins especially in the young chloroplasts[23], and light promotes the incorporation of amino-acids labelled with carbon-14 into proteins[24]. The presence of amino-acid activating enzymes in chloroplasts has been indicated together with the possibility of a coupling with photophosphorylation by means of adenosine triphosphate[25]. Other data which suggest that proteins may be synthesized in illuminated chloroplasts have been briefly reported and reviewed[26]. Recently, strong evidence has been obtained that the synthesis of fatty acids also occurs in chloroplasts and is dependent on photophosphorylation[27-29]. It is therefore probable that the synthesis of both lipids and proteins, two of the chief structural components of chloroplasts, is closely related to photosynthetic activity in developing leaves.

On the other hand, there is evidence that light may influence the size and protein content of the plastids of some etiolated leaves by mechanisms other than those of normal photosynthesis. In leaves of bean (*Phaseolus vulgaris*), in contrast to barley, light has an important morphogenetic action on leaf expansion; relatively brief exposure to red light causes the lamina to develop as well as changes in the plastids[30]. But it is evident that prolonged exposure to light is necessary for the differentiations of grana and normal development of chloroplasts in these leaves[31].

The relationship between nucleic acids and protein synthesis in chloroplasts is of particular interest with regard to the control of their development and the inductive action of light. Distinctive ribosomes have been isolated from chloroplasts of spinach[32] and of *Euglena*[33]. The RNA of *Euglena* plastids has a base composition different from that of the microsomes; moreover, the formation of this distinctive RNA is induced by light and precedes the increase of proteins associated with the differentiation of chloroplasts[34]. In young barley leaves the relatively high level of RNA during protein synthesis does not appear to be greatly influenced by light, but the possibilities of changes in base composition have not yet been fully explored. With regard to the metabolism of nucleic acids, additional evidence for the presence of DNA in the chloroplasts of some algae and higher plants has recently been reported[35,36] and may have an important bearing on the mechanisms underlying the genetic autonomy of plastids and the control of their differentiation.

The hypothesis of a relatively independent mechanism of protein synthesis, closely coupled with the photochemical activities in developing chloroplasts, is consistent with many of the observations we have so far made with young barley leaves. It is probable that the mechanism is particularly active during the development of grana and other lamellar structures of the plastids and that a phase of protein synthesis precedes that in which carbohydrates are the chief stable products of photosynthetic assimilation of carbon dioxide. A more critical test of this hypothesis is now being made by means of labelled metabolites.

We thank the Agricultural Research Council for the award of a research studentship to one of us (M. J. C. R.).

ASTROPHYSICS

Deficiency of Metals in Population II Stars

In a recent communication under this title Bashkin[1] has attempted to explain the deficiency of heavy elements in Population II halo stars by arguing that a separation between neutral atoms and ions is possible through electromagnetic means and that, since the ionization potentials of the metals are in general low, they will be confined to the disk while the neutral atoms can diffuse into the halo. This proposal can be severely criticized on several grounds.

(1) Abundance analyses which were not available at the time of Bashkin's communication have now been completed for several extremely metal-poor stars[2,3]. These analyses are of considerably higher accuracy than previous work because the stars are relatively bright and spectra of high dispersion were utilized. In Table 1 we list abundances of various elements, representative of different ionization potentials, in metal-poor stars. After each element we list the first and second ionization potentials, since the second ionization is probably important for some elements. Finally, we list the logarithm of the ratio of the element to hydrogen minus the same quantity for the Sun, and the source of the data. The abundances are probably accurate to a factor of 2 and are surely better than to a factor of 3. We have listed only a few elements, each of which is representative of a certain first or second ionization potential. Abundances of numerous other elements are listed in the references, most of the other observable elements have first ionization potentials between 6 and 8 volts. they generally show the same deficiency as does iron except for some heavy elements in *HD* 122563 which behave like barium.

Table 1 IONIZATION POTENTIALS AND MEASURED ABUNDANCES RELATIVE TO THE SUN

Element	First ionization potential (eV)	Second ionization potential (eV)	Log $\frac{N_t}{N_H}$ − Log $\frac{N_t}{N_H}$ ($\odot$)	Source
O	13.6	35.0	−1.7	*TY* Vir and *SX* Her (ref. 3)
			< −1.7	3 metal-poor giants (ref. 2)
C	11.2	24.3	−2.0	*HD* 140283 (ref. 4)

Mn	7.4	15.6	−3.3	3 metal-poor giants (ref. 2)
Ca	6.1	11.8	−2.75	3 metal-poor giants (ref. 2)
Ba	5.2	10.0	−4.75	*HD* 122563 (ref. 2)
			−2.90	*HD* 165195 and *HD* 221170 (ref. 2)
Na	5.1	47.1	−2.95	3 metal-poor giants (ref. 2)

Bashkin predicts that elements with large ionization potentials should behave as does hydrogen. We note from Table 1 that oxygen, which has almost exactly the same ionization potential as hydrogen, shows the same deficiency as iron in the two variable stars *TY* Virginis and *SX* Herculis[3]. In the three metal-poor red giants[2] oxygen was not discussed in the original paper because the lines could not be found and hence only an upper limit could be set on the abundance. This upper limit, however, is 1/50 of the normal ratio of oxygen to hydrogen. Carbon has the second largest ionization potential in Table 1 and was found by Baschek to have the same deficiency as iron in the metal-poor sub-dwarf *HD* 140283 (refs. 4, 5). Sodium has the lowest ionization potential and shows the same deficiency as does iron. Calcium and barium have such low second ionization potentials that they are mostly doubly ionized in interstellar space, but the ratio of calcium to iron is normal in metal-poor stars as is barium except in *HD* 122563 in which barium and other elements from strontium to europium are deficient by a factor of 50 more than is iron.

Next we point out that manganese, the ionization potential of which is within 0.4 eV of that of iron, is deficient with respect to iron by a factor of 3. This strange ratio of manganese to iron is found in numerous metal-poor stars[6]. To illustrate these arguments we use all the data for the two metal-poor red giants, for which we have abundances of the largest number of elements, in Fig. 1.

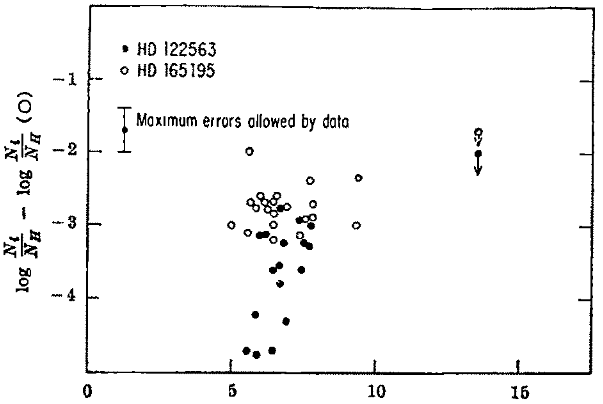

Fig. 1

Finally we direct attention to the *B*-type star in the galactic halo, *BD* + 33°2642, studied by Traving[7]. He found this star to be deficient in carbon, nitrogen, oxygen, magnesium and silicon by factors of 5–10 with no correlation with the first ionization potentials which range from 7.6 eV for magnesium to 14.5 eV for nitrogen.

(2) We wish to point out that all metal-poor stars were not formed in the halo. Of the three extremely metal-poor red giants discussed here, two (*HD* 122563 and *HD* 165195) have very small velocity components perpendicular to the galactic plane[2]. The sub-dwarf already mentioned, *HD* 140283, is also moving in a highly elliptical orbit, but its motion perpendicular to the plane is small.

The points discussed here concern the observations. Further objections can be raised on theoretical grounds against the proposed hypothesis.

(3) It is implied in Bashkin's first paragraph that ions will be confined to the galactic disk where there is a magnetic field, and neutral atoms will not. However, the evidence from the halo radio emission indicates that the magnetic fields extend into the halo region and there is no reason for believing that the magnetic field configurations of disk and halo are closed and separate. If a single ion could be given a velocity sufficient for it to be ejected into the halo, there is every possibility that the magnetic field connexion between disk and halo would allow this to occur.

(4) For any separation of the type proposed in Bashkin's first paragraph it is necessary for an atom to be given an outward velocity of several hundred kilometres a second. No mechanism for doing this is proposed other than a comment that particles in the high-velocity tail of a Maxwell–Boltzmann distribution may have high enough velocities. However, if the interstellar material is

composed of cool clouds with temperatures ~ 100° K and ionized clouds with temperatures ~ 6,000° K, the evaporation of particles with these energies is negligible.

(5) Bashkin seems to assume that the interstellar medium can be considered as made up of single particles moving in magnetic and gravitational fields. However, it must be stressed that it can only be considered as a continuous medium containing a variety of energy sources which is acting under gravitational and magnetic forces. That the viscous forces are strong is shown by the fact that only a very small ionized component of the gas is sufficient to couple the magnetic field to the neutral component[8,9]. Thus the picture of single atoms migrating into the halo is unrealistic.

Bashkin also remarks that the abundance of helium in Population II stars is incompatible with the nucleosynthesis theory. However, it has been shown elsewhere[10] that this is not so.

We conclude that Bashkin's proposal is unacceptable, and that the usual explanation of the abundance differences among stars as being due to the processes of nucleosynthesis and stellar evolution is to be preferred.

This work has been supported in part by the Office of Naval Research, the National Aeronautics and Space Administration and the National Science Foundation.

[10] Burbidge, G., *Ann. Rev. Nuclear Sci.*, **12**, 537 (1962).

THE objections raised by Wallerstein and Burbidge to my proposals are themselves subject to question.

(1) The accuracy quoted by Wallerstein and Burbidge for the abundance measurements exceeds or ignores the claims of the original authors. Thus Wallerstein *et al.*[1] mention (maximum) errors of a factor of 4 in the (Fe/H) ratio for *HD* 165195 and *HD* 221170, and a factor of 2 for *HD* 122563. For the other elements cited by Wallerstein and Burbidge, an additional error of a factor of 3 is given by Wallerstein *et al.*[1] in the (element/iron) ratio. These errors omit the effect, possibly large and in the direction to reduce the under-abundances, of the contribution of Raleigh scattering to the opacity[1,2]. Deutsch[2] in particular has found that the apparent under-abundance of the metals in Mira stars is reduced from a factor of one hundred to one of three when Raleigh scattering is considered. Baschek[3] indeed finds carbon to be deficient in *HD* 140283, but his result is a factor of ten higher than that of Aller and Greenstein[4] and he notes that a change of 100° K in the assumed effective temperature causes the deduced carbon abundance to vary by a factor of 1.7. Baschek's result[5] on the abundance of nickel in *HD* 140283 differs by a factor of five from the value obtained by Aller and Greenstein[4]. Wallerstein *et al.*[1] state that the data on elements from strontium to europium are so scanty that any theoretical treatment must be cautious. The alleged[6] under-abundance of manganese relative to iron is to be viewed with reserve because of discrepancies between authors. For example, for *HD* 140283 Baschek[5] gives [Mn/Fe] as +0.51, while Aller and Greenstein[4] give +0.01. One must remark that a small systematic error in Wallerstein's results[6] on [Mn/Fe] could account for his under-abundance of manganese, and further work on this point would be helpful. The foregoing uncertainties in the data cannot be neglected in attempts to interpret stellar abundances.

The relevance of Traving's *B* star[7] is not understood. Since that star is almost certainly far younger than the galaxy, its chemical composition is not simply related to the initial condition of the galaxy. It is entirely reasonable that young, isolated, halo stars should be deficient in all elements more massive than helium simply because of gravitational attraction between those elements and the disk. What is surprising about *BD* +332642 is that the helium content is normal[7]. This evidence that uncondensed matter in the halo is helium-normal may be further justification for the idea presented in my original communication that ionization and the galactic magnetic field significantly affect stellar compositions in the halo region.

The statement that Burbidge[8] has satisfactorily explained the (He/H) ratio in Population II stars seems to me to be in serious error. He emphasizes the discrepancy between the observed (He/H) ratio (0.17) and that calculated (0.019) on the assumption that all the galactic helium was built out of hydrogen in stellar interiors and lists four different, speculative hypotheses to account for this divergence. One of his suggestions leads to the conclusion that stars of small mass should have abnormally low (He/H) ratios. This is apparently contradicted by Traving's work[7], on Barnard's star, which he finds to have a mass of 0.2 M_0 but a (He/H) ratio only half normal.

(2) Of the stars mentioned by Wallerstein and Burbidge in the preceding communication, only *HD* 165195 is definitely not a halo star, but no evidence is advanced that this star was formed near the galactic plane.

(3) Certainly the original galactic field extended into the halo region. Equally certainly, that field had a gradient and a time-dependence which could have contributed the disk-ward force I suggested. Lynds and Sandage[9] have shown how, under some conditions, a galactic magnetic field can very effectively channel the motion of galactic matter. It would be interesting, if observationally possible, to look for element differentiation in *M* 82. According to my model, the filaments should be rich in metal and poor in helium. The coupling between ions and neutral particles by virtue of collisions and induced-charge effects is an important point. My original communication noted that charge exchange could occur and that the magnetic field would be effective only for such time as a given particle was actually ionized.

(4) I reiterate that the normal (He/H) ratio in Population II stars and the virtual identity of the (metal/H) ratios for young and old stars in the galactic disk present an unsolved problem in the theory which attributes all stellar abundance differences to stellar nucleogenetic processes.

I thank Miss Barbara Middlehurst for useful discussions.

GEOPHYSICS

Lunar Tides in the Equatorial Electrojet and in the Ionosphere over the Magnetic Equator

An abnormally large value of the solar daily range of the horizontal magnetic intensity, H, found at stations within a few degrees from the magnetic equator has been ascribed due to eastward electric currents flowing in the lower ionosphere during the daylight hours and known as equatorial electrojet[1] A longitudinal effect in the strength of the electrojet with a maximum in the American zone has been shown by Rastogi[2]

Bartels and Johnston[3] showed the existence of abnormally large lunar tidal effects in the range of H at Huancayo I (ref 4) showed that the enhancement in the tidal effects in the range of H is confined, within a few degrees. around the magnetic equator very similar to the equatorial electrojet I have also demonstrated a longitudinal effect in the lunar tides in range of H similar to that in the equatorial electrojet[5]

The existence of enhanced lunar tidal effects in the critical frequency f_0F_2 of the F_2 region of the ionosphere confined within a few degrees around the magnetic equator similar to the latitudinal variation of electrojet strength has been shown[6,7] The amplitude of lunar tide in f_0F_2 over the magnetic equator was largest in American intermediate in African and least in Indian zones, which is very analogous to the longitudinal variation of the equatorial electrojet

To study further the relations between the lunar tidal effects in f_0F_2 and in the electrojet analyses of midday (11–13 h mean) values of f_0F_2 at Huancayo over the years 1938–46 plus 1951–60 have been analysed by me and have been compared with the similar analyses of range in H by Bartels and Johnston[3]

In Fig 1 are drawn the harmonic dials showing the seasonal variations in the coefficients of lunar semimonthly variations in f_0F_2 computed by me and in the range of H derived from Bartels and Johnston's[3] paper The phase of lunar tide is denoted in terms of lunar age when the maximum positive deviation is obtained The data covering the period 1938–46 and 1951–60 are used for f_0F_2 and 1922–39 for range of H Each point is thus derived from about 20 lunations Probable error circles are drawn to show the statistical significance of each determination It is seen that the errors are much smaller than the amplitude and each of the determinations may be taken as significant

There is a remarkable similarity in the seasonal variations of the lunar tidal effects in the f_0F_2 and the range of H The change of the amplitude of lunar oscillation in both f_0F_2 or in range of H from their greatest values in January to their smallest values in June or July is quite marked The total change of L_2 amplitudes between the two seasons are 0 56 Mc/s and 19γ for f_0F_2 and the range of H respectively The sum of probable errors in the smallest and largest values of L_2 amplitudes is 0 06 Mc/s and 5γ The difference of L_2 amplitudes is thus about 5–10 times the sum of the probable errors

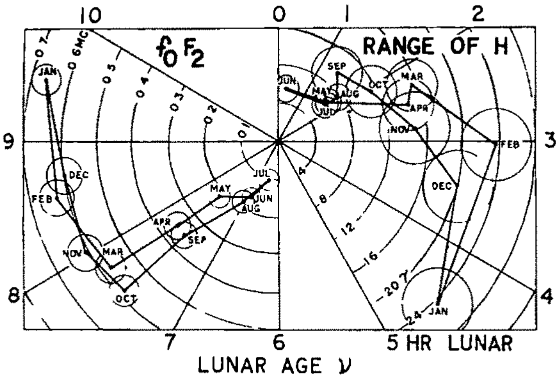

Fig 1 Harmonic dials showing the coefficients of lunar semi-monthly oscillations in f_0F_2 and in the solar daily range of H during different months at Huancayo

Further, there is a systematic shift of the phase of L_2 oscillation with season for both f_0F_2 and range of H, the crest of the wave occurring earlier in June–July than in January The difference of phase between the L_2 oscillations in f_0F_2 and range of H for any of the particular months, is very nearly 6 h, indicating an antiphase relationship between the two oscillations

The seasonal and latitudinal variations in the lunar tidal oscillations in f_0F_2 close to the magnetic equator demonstrate a very close association between the higher regions of the ionosphere and the equatorial electrojet situated in the lower portions of the ionosphere The exact mechanism of such an association is still to be worked out A fuller paper describing the lunar variations in H and f_0F_2 at Huancayo will be published later

SEISMOLOGY

Seismo-magnetic Effect and the Possibility of Forecasting Earthquakes

The existence of a correlation between magnetic disturbances and seismic activity has been suspected for nearly a century, but so many of the early observations were due solely to the mechanical vibration of magnetometers by seismic waves that when Lapina[1] reviewed the subject in 1953 she concluded that no effect had been satisfactorily demonstrated However, sufficient evidence had been accumulating in Japanese literature to justify a renewed examination of the problem

The approach of Japanese scientists was summarized by Kato and Takagi[2], who compared magnetic surveys before and after earthquakes and plotted differences which they associated with the seismic activity They presumed that the magnetic effects were due to thermal changes accompanying the earthquakes since a local rise in the Curie point isotherm (depth at which the temperature is equal to the Curie point of the dominant magnetic mineral) demagnetizes a certain volume of rock and causes a change of field at the surface However, the required movement of the isotherm is much more rapid than thermal diffusion will allow

The thermal explanation is untenable, but its acceptance has delayed recognition of the fact that seismomagnetic effects must be due to the piezomagnetic properties of rocks the magnetizations of which change reversibly with the stress applied to them Kalashnikov[3] appears to have been first to consider seriously the piezomagnetic properties of rocks He initiated laboratory experiments, the most significant of which are those of Kapitsa[4], who found that the susceptibilities of typical basaltic type rocks were reduced in the direction of an axial compression by 0 8 × 10^{-4} to 1 3 × 10^{-4} per 1 kg/cm^2 of stress, and increased by rather less than half this amount in the transverse direction Using these results, Kalashnikov[3] calculated possible magnitudes of seismo-magnetic effects, but he made very unfavourable assumptions about the geometry of the stressed rocks in the region of an earthquake and his conclusion was discouraging The maximum change he expected, of the order 0 5γ (0 5 × 10^{-5} œrsted), is scarcely observable

More recently the controversy over the influence of piezomagnetic effects on palæomagnetism has led to renewed investigation of piezomagnetic effects in rocks The theory of the subject recently reviewed by me[5], but still not entirely adequate, shows that susceptibility χ and thermoremanence I_R, measured in the direction of an axial compression σ kg/cm², are reduced by the stress approximately as

$$\frac{1}{\chi}\frac{d\chi}{d\sigma} = -1\ 1 \times 10^{-4} \text{ cm}^2/\text{kg}$$

$$\frac{1}{I_R}\frac{dI_R}{d\sigma} = -3 \times 10^{-4} \text{ cm}^2/\text{kg}$$

In the transverse direction magnetization is increased by nearly half these amounts

These figures allow a direct calculation of the surface magnetic field anomaly due to any distribution of stress in magnetic rocks The piezomagnetic moment of any element of rock due to shear stress across a fault which makes an angle φ to the direction of magnetization is an incremental moment ΔI, the magnitude of which is represented by the foregoing equations and the orientation of which is $(2\varphi \pm \frac{\pi}{2})$, the alternative signs representing right-lateral and left-lateral faults

The pattern of shear stress release due to transcurrent movement at a shallow earthquake, epicentred at (0 0) in (x, y) co-ordinates, expressed as a fraction of the stress σ_0 at the origin, can be conveniently represented by a simple analytical expression of the form

$$\frac{\sigma}{\sigma_0} = \frac{1 + y^2 - x^2}{(1 + y^2 + x^2)^2}$$

the stress being assumed constant along any vertical line

By numerical integration of the dipole law of force the magnetic field at the surface, due to a distribution of dipoles corresponding in strength to the intensity of the stress, can be calculated for any field component and for any orientations of magnetization and fault movement In Fig 1 the anomaly in vertical field due to movement along a fault directed magnetic east–west is plotted, assuming that the horizontal component of magnetization in the rock is directed to the magnetic north Its similarity to the vertical field anomaly of the Riku-U earthquake, plotted by Kato and Takagi[2] and reproduced in Fig 2, is obvious, although the Riku-U measurements were made more than 60 years ago and were too limited to give more than an indication.

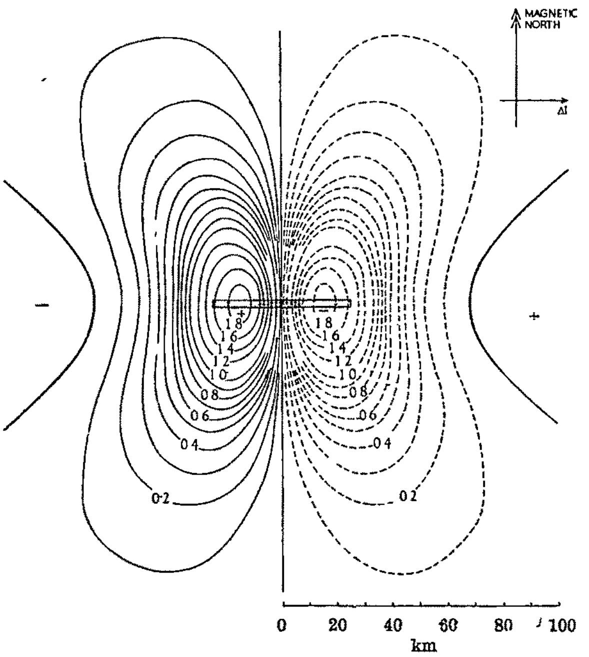

Fig 1 Intensity contours of the change in vertical component of magnetic field arising piezomagnetically from movement along an east west fault Figures on contour lines give the ratio of change in field to the vectorial change in magnetization at the point of maximum stress intensity

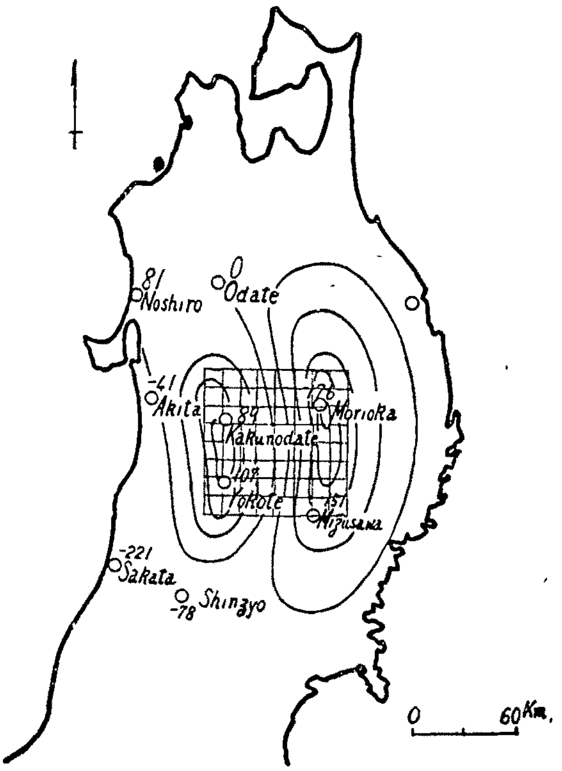

Fig 2 Contours of change in vertical field derived from magnetic surveys before and after an earthquake at Riku-U, Japan Figure taken from the paper by Kato and Takagi (ref 2)

The magnitude of the magnetic changes is determined by the intensity of magnetization of the rock and intensity of the stress released, both of which may be very variable Considerations of earthquake energy release indicate that 100 kg/cm² is a reasonable value to assume for the maximum shear stress release, so that maximum changes of 3 per cent in remanence and 1 per cent in induced magnetization are to be expected Magnetic anomalies of 10γ (10^{-4} œrsted) to 100γ (10^{-3} œrsted) are then expected in regions where the remanence of underlying igneous rock is 10^{-3} E M U to 10^{-2} E M U A surface layer having a kilometre or so of non-magnetic sediments scarcely affects this result if the magnetic rock extends to a depth of about 25 km

Such anomalies are readily observable Further, an earthquake must be preceded by a build-up of stress, normally over a period of months, and the magnetic effect must therefore give a pre-indication at least in many cases[6] The possibility of forecasting earthquakes on this basis deserves urgent consideration because magnetic instruments of the required accuracy are cheap, simple and reliable A weekly survey of the total magnetic field, using a proton precession magnetometer with a second one as a base instrument for comparison may well be sufficient to indicate the location of an impending earthquake with considerable accuracy

More extensive calculations of seismo-magnetic anomalies are in preparation for publication

GEOLOGY

Geological Effects on Surface Waters in Natal

During the course of a hydrobiological survey of the Umgeni River, Natal, it was found that the dissolved inorganic material in various tributaries of the main river showed characteristic differences in composition. It was considered that these differences arose from the fact that the tributaries drained catchment areas formed from rocks of different geological formations. This was therefore investigated further.

Five pairs of streams in Natal were selected, care being taken to ensure that the water of each stream was unpolluted, that the catchment of each stream was geologically homogeneous and that the two streams of each pair were geographically far apart. One pair of streams drained Beaufort rocks, one Ecca rocks, one Dwyka rocks, one Table Mountain Sandstone and one outcrops of basement granite, so that the principal geological formations of Natal were all included in the investigation. Samples were taken from each of the ten streams during the dry and the rainy seasons and biological checks were made during the dry season to confirm the absence of pollution. Each of the twenty water samples thus obtained was analysed for the major inorganic solutes and the results were expressed in such a way as to eliminate the effects of mere dilution or concentration. This was accomplished by finding the total of the concentrations, in p.p.m., of calcium, magnesium, sodium, potassium, carbonate, sulphate, chloride, and silica (the concentration of carbonate used here being a conventional value obtained by multiplying by 0·6 the total alkalinity expresed as p.p.m. of calcium carbonate) and expressing each concentration as a percentage of that total.

It was found that the analyses of the streams of each pair then showed close similarities and differed characteristically from those of the streams of other pairs. Thus it was concluded that the differences between the pairs were real and due to differences in geology.

Table 1 shows the mean results for each geological formation as well as figures considered to apply to Tertiary and more recent formations (deduced from analyses from other sources).

Table 1

Geological formation	Mean T.D.S. (p.p.m.)	Calculated percentages Ca	Mg	Na	K	CO_3	SO_4	Cl	SiO_2
Beaufort	38	8·7	4·2	8·0	1·9	41·0	6·0	6·9	23·3
Ecca	52	7·3	4·7	10·1	1·1	44·1	7·6	6·2	18·9
Dwyka	314	8·3	7·3	19·4	0·7	34·3	2·8	23·0	4·2
Table Mountain Sandstone	84	4·3	4·7	19·9	2·2	20·7	8·1	23·8	16·3
Granite	134	6·8	5·3	21·2	1·0	29·5	5·4	21·0	9·8
Tertiary and younger	175	18·0	2·2	14·1	1·5	31·0	6·1	22·5	4·6

Examination of these results (which is aided by any form of graphical representation) shows that the surface waters from Beaufort and Ecca rocks are very similar. This would be expected in view of the lithological similarities between these rocks. The surface waters from Table Mountain Sandstone and granite rocks differ from these in having higher proportions of sodium and chloride, although no ready explanation of this has yet been found. The waters from Dwyka rocks show these features also, together with a lower proportion of silica and a very much higher concentration of total dissolved solids. It is thought that these characteristics arose from the presence in Dwyka formations of tillite made up of relatively unweathered rock fragments which are only now being exposed to the effects of weathering and leaching. Some confirmation of this view arises from the fact that the figures assumed for waters from younger rocks (Tertiary to Recent), which are also relatively unweathered, are rather similar to those obtained for Dwyka waters.

These results are proving very useful in establishing a background for the interpretation of water analyses made in the course of later river surveys.

A Mid-Labrador Sea Ridge

J. T. Wilson[1] has recently speculated on the presence of a median ridge extending through the Labrador Sea and up Baffin Bay. He suggested that its presence had not been noted because of insufficient sounding data, and that its presence could be verified by additional sounding data.

Although the Labrador Sea is not the best-sounded area of the world oceans, there are sufficient observations to determine that no obvious ridge exists. There are, however, several isolated peaks along the centre of the sea which suggest the presence of buried topography of some magnitude[2].

During 1960 and 1961 joint cruises were made in the Labrador Sea by C.N.A.V. *Sackville*, under the jurisdiction of the Atlantic Oceanographic Group of the Fisheries Research Board of Canada, and R.V. *Vema* of the Lamont Geological Observatory of Columbia University. The research programmes during these cruises were varied and included oceanographical, biological, geological, and geophysical investigations.

Table 1

Station	Latitude *A*	Longitude *A*	Latitude *B*	Longitude *B*	Velocity (km/sec)	Thickness (km.) *A*	*B*
159–160	56–38 N.	52–01 W.	57–01 N.	51–31 W.	1·49	3·43	3·44
					1·98	0·96	0·97
					3·20	1·93	1·33
					5·47	0·84	2·19
					7·67		
161–162	58–31 N.	49–19 W.	59–05 N.	48–37 W.	1·49	3·41	3·23
					1·95	1·51	1·74
					5·54	1·68	2·32
					7·58		

As a part of the 1960 programme, four seismic refraction profiles were observed in the deep part of the Labrador Sea (> 3,000 m) on board the two vessels. The observational methods have been described by Officer *et al.*[3] and the data were reduced following the methods of Officer and Wuenschel[4], Ewing *et al.*[5], and Sutton and Bentley[6]. The results of these observations are given in Table 1 and indicate that the structure beneath the bottom of the Labrador Sea is not that of the typical ocean basin but more closely resembles that found by Ewing and Ewing[7] along the Mid-Atlantic Ridge. There was no indication of a ridge-like feature in the echo-sounding records from the two vessels, however, the major topographic feature being the extension of Mid-Ocean Canyon No. 1 (ref. 8), afterwards traced to 61° N. during the 1961 cruise.

In 1961 a new technique, seismic profiling[9], became available and was put to use during the joint cruise in the Labrador Sea. With this technique, a reflexion method using small explosive charges fired at 2-min intervals, it became possible to see the structure of the rock surface beneath the sediments. Profiler sections were made along two tracks across the Labrador Sea, one from north-east of Newfoundland to Julienhaab, Greenland, the other west from Julienhaab towards Hudson Strait at about 61° N. (Fig. 1).

The results along the two lines are quite similar. Near the continental margins of Greenland and North America, the rock surface is buried deep beneath the sedimentary cover and in these areas it is not possible to detect the rock surface beneath it. As the geographical centre of the Sea is approached, the rock surface (5·5 km/sec) appears on the profiler records and in each case the maximum elevation of this surface is very near to the geographical centre of the Labrador Sea. Along the northern line it is still buried beneath about a kilometre of sediments while to the south it appears above the surface in several places.

Possible extension of this ridge north and south is difficult to verify. It may swing around the tip of Greenland to join the Mid-Atlantic Ridge. There are a few isolated peaks indicated on the bathymetric chart[2] which might represent the highest points of buried topography. On the other hand, it may just die out and disappear. To the north, a shallow (400 m) sill separates the Labrador Sea from Baffin Bay. Lg phases from earthquakes have been observed to propagate across this sill[10]. If continental structure is required for propagation of lg phases[11], then the ridge as such must terminate against this sill and its continuation farther north is questionable. If, on the other hand, lg phases will propagate through a buried ridge structure, then the ridge may continue into Baffin Bay.

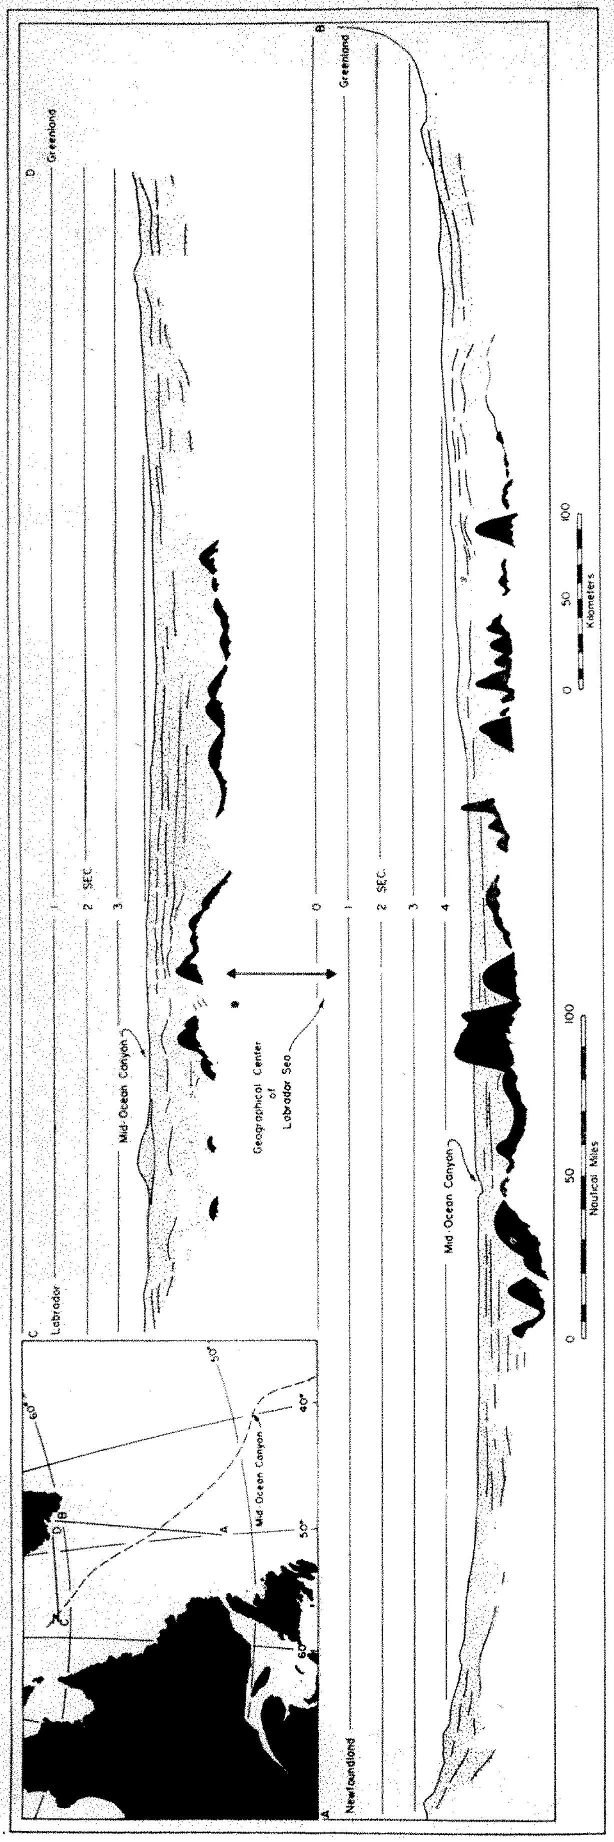

Fig. 1

The symmetry of the Labrador Sea ridge, midway between North America and Greenland, suggests a common mode of origin with the mid-ocean ridge system. There are, however, some significant differences. No distinctive magnetic anomaly, such as is frequently found over the rift in the middle of the mid-ocean ridge[11], was observed and only a few earthquakes have been recorded from this area[12]. These facts, plus the depth of burial of the ridge by sediments and its lower elevation, suggest that the Labrador Sea ridge developed at an early geological time and that its development ceased before it reached the mid-ocean ridge stage.

New Zealand Mid-Tertiary Stratigraphical Correlation

THE apparent absence of certain stratigraphically important planktonic Foraminifera from the Australian and New Zealand Tertiary rocks has made it difficult to correlate these sequences with the more tropical Tertiary sequences[1]. A recent examination of rocks from the North Auckland region of New Zealand has yielded what appears to be a warmer water fauna.

One of the most important short-ranging species in the well-documented Trinidad Oligocene–Miocene section is *Globorotalia kugleri* Bolli[2]. In New Zealand, Hornibrook[3] recorded possible specimens of this species from the Kopuku section, south of Auckland City, from rocks of Otaian age. A few Otaian samples from North Auckland have yielded definite specimens of *G. kugleri*. Samples slightly older than this have yielded specimens of *Globigerina ciperoensis ciperoensis*.

The initial appearance in time of *Globigerinoides trilobus* (Reuss) has until recently been placed at the base of the Awamoan stage[4]; but there is slight evidence that it may start a little earlier than this, possibly in the top of the Otaian[3]. This level would be approximately equivalent to the top of the *G. kugleri* zone in Trinidad (Fig. 1).

New Zealand stages (ref. 5)	Trinidad zones (ref. 2)	New Zealand stages
Awamoan Hutchinsonian Otaian Waitakian	*C. stainforthi* *C. dissimilis*	Awamoan Hutchinsonian
	G. kugleri	Otaian
	G. ciperoensis ciperoensis *G. opima opima* *G. ampliapertura*	Waitakian Duntroonian Whaingaroan

Fig. 1 Correlation of the New Zealand stages with the planktonic foraminiferal zones of Trinidad

Eames, Banner, Blow and Clarke[5] have correlated the Waitakian–Awamoan rocks in New Zealand with the *stainforthi* zone of Trinidad. The recent discovery of definite *G. kugleri* in Otaian rocks shows that this is completely wrong. There is therefore very little evidence for their hypothesis, which shows a large disconformity below the Waitakian Stage in New Zealand.

With further work, now in progress in New Zealand on the Tertiary planktonic Foraminifera, it is hoped to establish a more accurate correlation of the Tertiary with rocks elsewhere.

PHYSICS

Charge Transfer associated with Temperature Gradients in Ice

THE deviation at temperatures above −7° C from the theoretical value for the charge transfer produced by temperature gradients in ice is shown to be a surface phenomenon.

Recent calculations[1] predict that when a steady temperature difference ΔT is maintained across a uniform specimen of pure ice a potential difference of magnitude $V = 2\Delta T$ mV is developed between its ends. This equation was tested by applying temperature gradients to cylinders of pure ice and was verified for temperatures below −7° C. Above this temperature, however, the measured potentials were greater than those predicted.

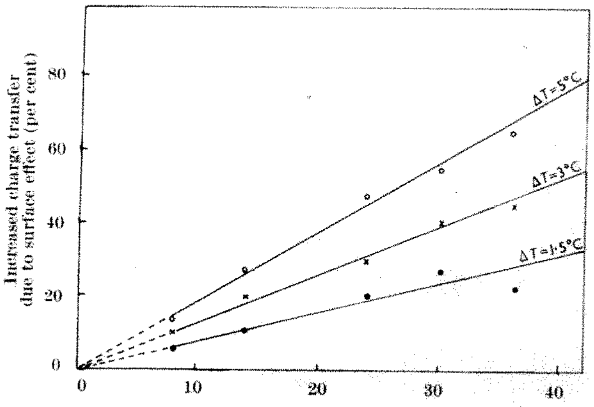

Fig. 1. Effect of the surface-volume ratio on the potentials developed across ice by steady temperature gradients (temperature of colder end of ice cylinder = −7° C)

In order to discover whether the accentuation of the potentials developed across the ice as the temperature of its warmer end approached 0° C was a surface-dependent phenomenon or not, the experiments were repeated for cylindrical specimens of ice of different surface-volume ratio. Curves obtained of V against ΔT for different values of this ratio are shown in Fig. 1. It is seen that as the ratio increases so does the divergence from the theoretical value. Although the accuracy of these experiments was not very great it is evident from the figure that if the straight lines are extrapolated back to zero surface-volume ratio they tend to pass through the origin, that is, showing that the divergence at high temperatures is solely a surface phenomenon, corresponding to an additional transport of charge along a surface layer having a larger variation of conductivity with temperature than the bulk ice. It is not possible to calculate the thickness of such a layer, since both its conductivity and its concentration of mobile ions are unknown.

Weyl[2] has suggested that the molecules on the surface of ice are disarranged and that this distortion extends a finite thickness into the ice. The thickness and adhesive properties of this 'liquid layer' vary with temperature in a similar manner to the divergence of the temperature-gradient potentials from the foregoing equation, but at present there is no direct evidence connecting these two surface properties of ice.

Epitaxial Growth of Silicon by Vacuum Sublimation

SINGLE crystal layers of silicon up to several μ thick have been deposited on to a heated single crystal silicon substrate from a sublimating source. We believe we can grow good epitaxial crystals at a lower growing temperature than previous experiments[1] by reducing the growth rate in a good vacuum free from contamination.

Silicon slabs of about 18 mm × 1·5 mm × 0·5 mm and 18 mm × 3 mm × 0·5 mm were used as the source and the substrate, respectively, with which preferably {111} planes were used. They were cut, polished, etched and cleaned before they were fixed to tungsten rods with tantalum clips so as to face the widest surfaces about

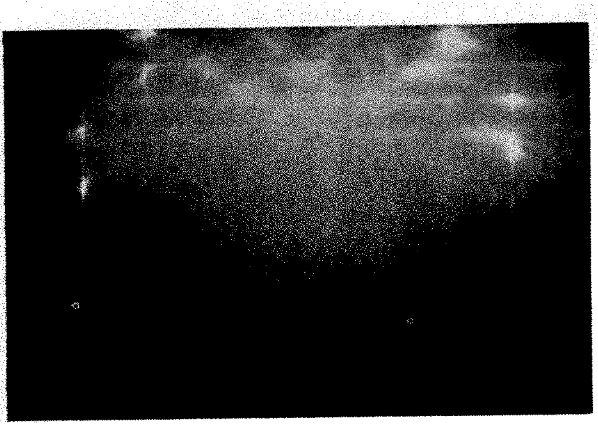

Fig. 1. Electron diffraction photograph of silicon epitaxially grown at 830° C

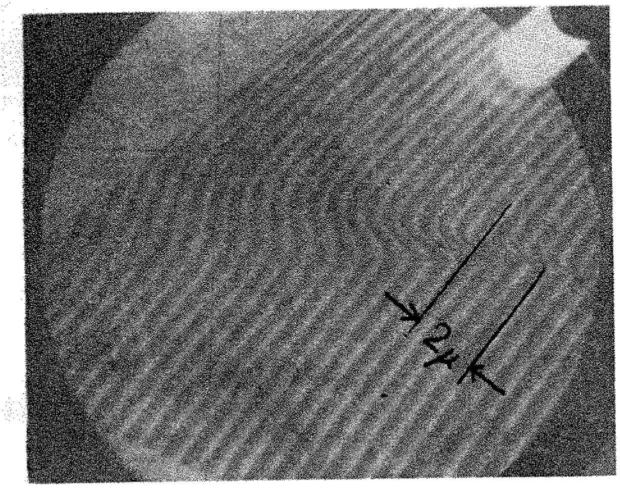

Fig. 2. Interference pattern measuring the thickness of the epitaxial deposit

10 mm apart from each other and sealed in a quartz tube which was evacuated with a Nippon Electric Co. Vac-Ion pump to as low as 10^{-8}–10^{-9} mm mercury. After a good vacuum was attained, both the source and the substrate were directly heated at 1,250° C for about 1 h by flowing a.c. current to the silicon slabs to bake out the adsorbed gas on the surfaces and to etch the substrate in order to get a clean surface[2], which is essential to obtain good epitaxial crystals.

While the temperature of the source was kept at 1,200° C for about 100 h, at which the sublimation rate is about 1×10^{-7} g/cm^2 (ref. 3), that of the substrate was maintained at various temperatures to observe the growing conditions. It was easier to grow shiny and flat epitaxial crystals at higher temperatures.

By keeping the substrate at 830° C for 50 h, we obtained a deposit about 2μ thick and the grown film was examined by electron diffraction at the electron energy of 100 keV. Fig. 1 shows the diffraction pattern revealing Kikuchi lines, which is evidence of the good quality of the crystal. The thickness of the deposited film is measured at the edges of the substrate, which are masked with the tantalum clips with an interferometer. The interference pattern in 546 mμ of a mercury vapour lamp is shown in Fig. 2.

P,n junctions with a maximum reverse breakdown voltage of 200 V have been obtained. The deposited layers of either *n*- or *p*-type were obtained, but the resistivity was not determined because the diffusion velocities of impurities[4] were comparable with the growth rate of the crystal, and the conventional bevelling and staining techniques were useless.

The advantage of epitaxial growth by sublimation is found in the result of the slow growth rate, that is, growth at lower temperatures, which may lead to the epitaxial growth of silicon on other crystals such as germanium or gallium arsenide. So far the growth on germanium is unsuccessful, probably due to the incompletely clean surface of germanium.

I thank Mr. S. Sakuma for help with the electron diffraction, and Drs. Y. Ishikawa and K. Hayashi for their advice.

Colour Centres in Sodium Cyanamide

IRRADIATION of pellets of sodium cyanamide at room temperature with ultra-violet from a high-pressure mercury lamp, or with 2-MeV electrons, results in the formation of a number of absorption bands. The results are shown in Figs. 1 and 2. Looking at Fig. 1, the bands occur at 4250 Å (band *A*) and 5000 Å (band *B*). In addition there is a broad region of absorption around 6500 Å (band *C*) and the possibility of a weak band at 3200 Å (band *D*). These bands bleach on heating, and with *A* and *B* light.

At higher temperatures (110° C) bands *A* and *B* are more intense after irradiation, while at 200° C thermal decomposition can also occur, which itself gives rise to absorption bands[1]. Of these the bands at 3400 Å and 5000 Å have been attributed to the presence of sodium produced by thermal decomposition.

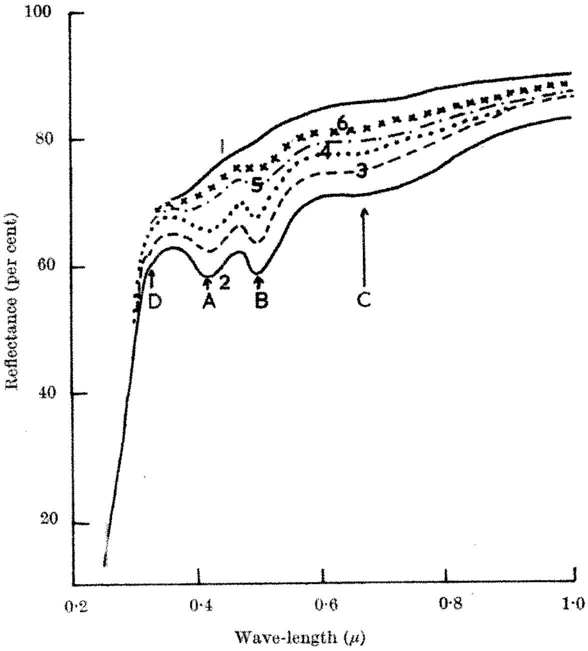

Fig. 1. Effect of ultra-violet irradiation at room temperature in a vacuum on the reflexion spectrum of sodium cyanamide (standard comparison $MgCO_3$). 1, Before irradiation; 2, after 2·5 h irradiation; 3, after 0·5 h anneal at 20° C; 4, after 1·5 h at 20° C; 5, after a further 0·5 h plus illumination with light of wave-length 5000 Å; 6, after a further 0·25 h plus illumination with light of wave-length 4250 Å

The spectra shown in Figs 1 and 2 are similar though, in the case of irradiation with 2-MeV electrons, band *D* is stronger while band *C* is scarcely resolved The intensities of *A* and *B* increase with dose, and tend to saturate, eventually forming a single band with a minimum at 4500 Å The results are similar to the build-up of *F* centres in sodium chloride[2] where the process of defect production is a two-stage one They are also similar to those obtained with sodium azide[3]

Qualitative measurements showed that both ultra-violet and electron-irradiated samples gave rise to an electron spin resonance signal with a *g* value near 2 0 , no such signal was observed in the case of unirradiated samples

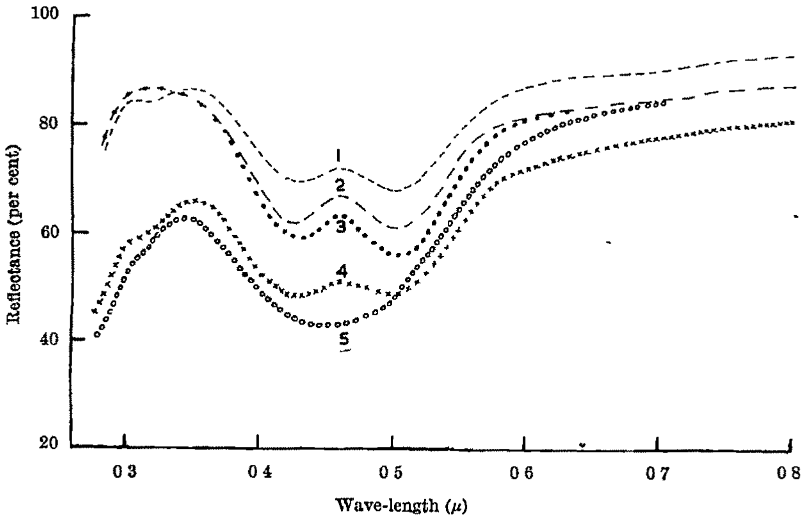

Fig 2. Reflexion spectra of sodium cyanamide pellets irradiated with 2-MeV electrons at room temperature 1, 3 megarad dose, 2, 5 megarad, 3, 15 megarad, 4, 30 megarad, 5, 60 megarad Irradiation was intermittent to avoid overheating, and dose-rate about 1 megarad/min

The results suggest that bands *A* and *B* are due to colour centres of the *F* centre type Band *C* appears more pronounced at higher temperatures of irradiation and coincides with a thermally induced band The properties of the band suggest either impurity or aggregate centres as the type most likely to be responsible The *D* band is best observed at low temperatures (about −100° C). since at high temperatures it may be masked by a thermally induced band at 3400 Å It occurs in the wave-length region normally associated with electron-deficient centres, and is therefore attributed to an unspecified *V*-type centre

It is not at present possible to give detailed information on the nature of the colour centres responsible for the *A* and *B* bands It is likely, however, that they originate from photochemical decomposition in a manner analogous to sodium azide[3], though in this case the efficiency of coloration is much less The experiments indicate that bands *A* and *B* are due to two forms of the same centre, and it is suggested that this is an R_3 centre which can have two orientations (sodium cyanamide is orthorhombic)[4] The R_3 centre would be formed from a divacancy in the manner

$$\square^{\square} + 3e \rightarrow \square^{\square} \quad (R_3 \text{ or } F'^{+}_{2}) \text{ centre}$$

CRYSTALLOGRAPHY

Nucleation of Gypsum Crystals

HETEROGENEOUS nucleation is an important process, and the nucleation of ice crystals in particular has been extensively investigated. The nucleation of crystals of gypsum has a theoretical and industrial interest but has received little attention This communication presents some observations on the capacity of various substances to nucleate gypsum from solution

The hydration of calcium sulphate hemihydrate appears to be initiated by the heterogeneous nucleation of gypsum crystals at favourable sites in mixtures of calcium sulphate hemihydrate and water[1–3] It should be possible, then, to assess the nucleating efficiency of a substance from its effect upon the rate of hydration

We have used the following procedure to determine the effect of various substances on the rate of hydration The material to be tested was added as a powder to 60 0 ml water, and then 100 0 g of finely divided calcium sulphate hemihydrate was added slowly to the mixture After stirring for 30 sec the paste was transferred to a Dewar flask The mixtures were made at 20 5° C The progress of hydration was followed from the increase in temperature and the justification for this procedure has already been given[4] The effect on the rate of the reaction was assessed from the induction period and the position of the curve of $\log_{10}\alpha$ plotted against time (α is the ratio of the increase in temperature divided by the final increase in temperature) The induction period was defined as the time taken for the rate of increase in temperature to reach 0 1° C/min

Despite the fact that hydration is initiated by the heterogeneous nucleation of crystals of gypsum, of the insoluble or sparingly soluble solids tested other than gypsum itself only synthetic γFeO OH has been found to have a significant effect on the rate of hydration The materials tested so far include ground glasses, silica, hæmatite, kaolinite, talc, and many other minerals and solids that for various reasons were suspected of being able to nucleate gypsum

The γFeO OH used in the work was prepared by oxidizing ferrous ammonium sulphate with potassium iodate and sodium thiosulphate[5] X-ray diffraction yielded the pattern of γFeO OH and showed that the material was poorly crystalline Atomic absorption spectroscopy showed that the preparations were free from such quantities of sodium and potassium that could produce an acceleration of the rate by a mechanism other than that of increased nucleation

An example of the effect of γFeO OH is shown in Fig 1, where $\log_{10}\alpha$ is plotted against time for an unaccelerated reaction and for hydration in the presence of 0 05 g γFeO OH The induction period of the unaccelerated reaction was 16 min and that of the accelerated reaction was 12 min Precipitated gypsum (0 5 g) produced almost the same results as the 0 5 g of γFeO OH Several preparations were tried and all were found to be effective

Observations under the microscope were also made on aqueous suspensions of γFeO OH and calcium sulphate hemihydrate, and crystals of gypsum could be seen growing from the particles of ferric oxide monohydrate

If epitaxy is occurring it would be expected that the spacings of the substrate and growing lattice would be similar within certain limits[6] Both gypsum and γFeO OH have layers of hydrogen bonds in the 010 planes and perfect cleavages parallel to the 010 planes Seeing that the oxide has to be ground to render it suitable for experi-

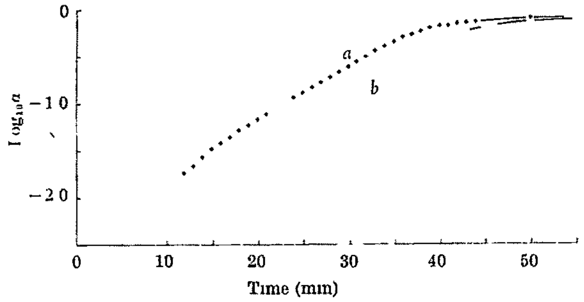

Fig 1 $\text{Log}_{10}\alpha$ plotted against time for 100 0 g calcium sulphate hemihydrate and 60 0 ml. water (*a*) 0 50 g γFeO OH added, (*b*) no additive The induction period for (*a*) was 12 min and for (*b*) was 16 min

ment, it is highly probable that there will be plenty of exposed (010) faces However, calculation shows that the agreement between the spacings of the two lattices is not such that the action of γFeO OH is obviously due to epitaxy on the 010 plane, which would seem to be difficult to reconcile with the experimental facts for another reason A mechanism of this type would result in the *b* direction of the growing gypsum crystals being perpendicular to the surface of the substrate, and growth in the *b* direction is slow If, indeed, orientated overgrowth of gypsum on faces of the microcrystals of γFeO OH is not occurring in mixtures of calcium sulphate hemihydrate and water, topographical features such as steps on the surfaces of the grains of γFeO OH may be providing favourable sites for the development of gypsum nuclei

We thank Mr C Lancucki for the X-ray examination of the samples of γFeO OH

X-ray Intensity Statistics of a Pair of Related Crystals

We have been investigating the problem of the probability distributions connected with the X-ray intensities of two crystals Two ideal situations may be considered (*a*) when the two crystals are fully related, that is, when the atoms in one form a part of the atoms in the other, (*b*) when they are unrelated, that is, when the atoms in the two structures are in entirely different positions It is of course assumed that the two unit cells are exactly the same or very nearly so When a protein crystal and its heavy atom derivative form an isomorphous pair, they are related in the foregoing sense, and the present investigation has resulted in the formulæ which could be used to test the isomorphism of such a pair of crystals The term 'relatedness' is used in preference to 'isomorphism' for the more general concept, following the suggestion of some senior crystallographers

We consider a pair of crystals, one containing P, and the other N, atoms ($P < N$, $N = P + Q$) Probability distribution functions can be derived for several variables connected with F_N and F_P, the structure amplitudes of the two crystals Specifically, three such have been considered, namely, the normalized difference

$$w = (|F_N| - |F_P|)/\sigma_N$$

the normalized product

$$Z = |F_N||F_P|/\sigma_N\sigma_P$$

and the normalized quotient

$$V = \frac{(|F_P|/\sigma_P)}{(|F_N|/\sigma_N)} = \frac{|F_P|}{|F_N|} \frac{\sigma_N}{\sigma_P}$$

where σ_P and σ_N are the root mean square intensities of the two crystals, that is, $\sigma_P^2 = <|F_P|^2>$ and $\sigma_N^2 = <|F_N|^2>$

The functions $P(u)$, $P(Z)$ and $P(v)$ all depend on whether the crystal is centrosymmetric or non-centrosymmetric Two situations have been considered in either case (*a*) when the crystals are related, and (*b*) unrelated, and detailed expressions have been derived in every case These are not given here, but only some of their properties will be considered It may be mentioned that the formulæ were derived on the assumption that the number of atoms in the crystals is large, so that the asymptotic distribution may be utilized for each crystal

All the expressions contain a parameter σ_1^2, defined by $\sigma_1^2 = \sigma_P^2/\sigma_N^2$, which is the ratio of the mean intensities due to the P atoms and the N atoms It is also the mean fractional contribution to the intensity of the N-atom crystal from the P atoms in the related case

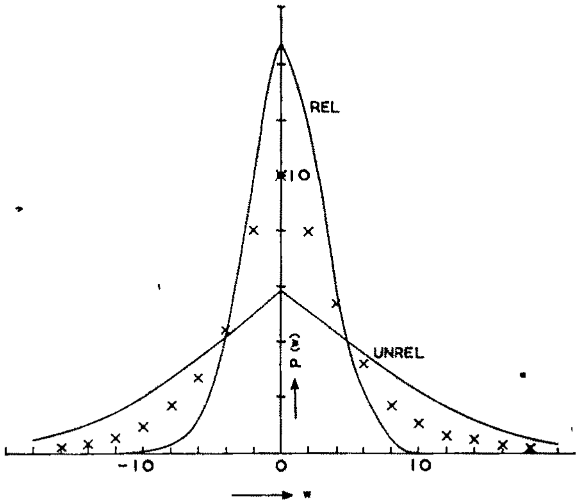

Fig 1 Theoretical probability distribution function $P(w)$ for the related and unrelated case in a centrosymmetric crystal, corresponding to $\sigma_1^2 = 0\ 9$ The crosses are observed data for the pair of crystals, caffeine and theophylline

Of the three variables w, Z and v, the distribution functions of the first and the third, namely $P(w)$ and $P(v)$, widely differ between the related and the unrelated cases These functions can therefore be used to test for relatedness As an example, the function $P(w)$ is shown in Fig 1 for the two cases, corresponding to a value of $\sigma_1^2 = 0\ 9$ It will be noticed that the curve is much sharper in the related case than in the unrelated case The data for $P(w)$, for the pair of crystals, caffeine[1] ($C_8H_{10}N_4O_2H_2O$) and theophylline[2] ($C_7H_8N_4O_2\ H_2O$) which differ only by a group CH_2 and which have very nearly the same unit cell dimensions and therefore expected to be isomorphous, are indicated by crosses It will be seen that these results fall in between the curves for the related and unrelated cases, showing that the isomorphism is not exact

In fact, it is possible to define a quantity "degree of relatedness" (or 'isomorphism'), γ, for such cases by the formula

$$\gamma = \frac{<w>_{\text{obs}} - <w>_{\text{unrel}}}{<w>_{\text{rel}} - <w>_{\text{unrel}}} \times 100 \text{ per cent}$$

which will make γ = 0 for the unrelated case and 100 per cent for the related case For the pair of crystals already mentioned, γ proved to be **38** per cent, showing that the isomorphism was far from exact A similar test with protein crystals will be very valuable for testing for isomorphism

The function $P(w)$ can also be used to calculate the R-value which is to be expected when a part of the structure (for example, the heavy atoms alone) is used for calculating the F_c's This follows from the relation

$$R = \frac{\Sigma||F_N| - |F_P||}{\Sigma|F_N|} = \frac{\int_{-\infty}^{+\infty} |w|P(w)\mathrm{d}w}{\int_{-\infty}^{+\infty} yP(y)\mathrm{d}y},$$

where $P(y)$ is the distribution function for a single crystal (centrosymmetric, or non-centrosymmetric, as the case may be), and is known A table of R as a function of $\sigma_1{}^2$ has been calculated for both the related and unrelated cases, and this has been found to be useful in checking whether the positions of the heavy atoms determined are correct or not

By calculating from $P(w)$ the integral $P_+ = \int_0^\infty P(w)\mathrm{d}w$, that is, the fraction of reflexions for which w is positive, it is possible to put the intensity data of two isomorphous crystals on the same relative scale The details are omitted

Thus, these statistical methods are found to have a number of applications to the study of isomorphous crystals However, it may be mentioned that the foregoing results correspond only to the type of isomorphism in which a small number of atoms are *added* to a crystal The extension of these studies to the case when the isomorphism is of the replacement type is possible and is under investigation

Crystallographic Data of Two Seleno-urea Derivatives

As part of an investigation of the crystal structure of several derivatives of seleno-urea and a metal (palladium) the unit cell and space groups of α-benzoyl β-phenyl seleno-urea and α-acetyl β-phenyl seleno-urea have been determined

(*a*) *α-benzoyl β-phenyl seleno-urea* Rotation and Weissenberg photographs, taken with copper $K\alpha$ radiation, showed that the unit cell is monoclinic with the dimensions $a = 19\ 97 \pm 0\ 03$, $b = 5\ 11 \pm 0\ 03$, $c = 13\ 15 \pm 0\ 03$ Å, $\beta = 104\ 0 \pm 0\ 3°$.

The space group is $P2/c$ The observed density was 1 6 g/cm^3 in agreement with the calculated value 1 54 g/cm^3 corresponding to four molecules of α-benzoyl β-phenyl seleno-urea per unit cell The absorption coefficient gave $\mu = 41\ 8$ cm^{-1}

(*b*) *α-acetyl β-phenyl seleno-urea* Crystals are monoclinic with the dimensions $a = 10\ 26 \pm 0\ 03$, $b = 22\ 43 \pm 0\ 03$, $c = 9\ 36 \pm 0\ 03$ Å, $\beta = 113\ 0 \pm 0\ 5°$, deduced from rotation and Weissenberg photographs Copper $K\alpha$-radiation was used The systematic absences are $0k0$ for k odd and $h0l$ for l odd, so that the space group is determined as $P2_1/c$ The density measured by flotation is 1 7 g/cm^3 The calculated value for eight molecules per unit cell gives 1 69 g/cm^3 The absorption coefficient for copper $K\alpha$-radiation is 3 6 cm^{-1}

CHEMISTRY

Detergent (Sodium Lauryl Sulphate)-splitting Enzyme from Bacteria

THE persistence of synthetic detergent compounds in treated sewage effluents and rural water supplies has become an increasing problem[1] Several investigations have been carried out, using methylene blue colorimetric and manometric techniques, of the bio-degradation of these materials by the mixed bacterial flora in sewage and river water[2] Payne and Feisal[3] succeeded in isolating from benthonic soils two strains of bacteria, of which one could utilize lauryl sulphate and the other both lauryl sulphate and alkyl benzenesulphonate as sole carbon sources Investigation of detergent metabolism at the enzyme-level has not yet been reported

Alkyl benzene sulphonates constitute the major class of detergent in use for household purposes and, therefore, play the greatest part in water pollution problems However, examination of the enzymatic degradation of these compounds is complicated by the enormous number of isomers to be considered On the other hand, alkyl sulphates are easily obtained in high purity without cross-contamination of isomers, inorganic sulphate, or other inorganic substances By examining the mode of action of alkyl sulphate-destroying enzymes as a model, clues might be obtained to facilitate investigation of enzyme action on alkyl benzene sulphonates Because it is well known that detergents denature proteins, one wonders how a detergent-destroying enzyme could escape denaturation The investigation recorded here was initiated with these problems in mind

With synthetic minimal media containing sodium dodecyl sulphate (SDS) as both carbon and sulphur source, a gram-negative bacillus was isolated from raw sewage water of the Baltimore Back River Sewage Treatment Plant (As proposed by Schwatz and Pewey, the term 'dodecyl' will be reserved for the true C_{12} radical, and the term 'lauryl' for the mixed aliphatic radicals (mainly C_{12} and C_{14}) derived from coconut oil (*Surface Active Agent*, Interscience Publishers, Inc, New York, 1949)) This strain could also utilize octyl, decyl, tetradecyl sulphate instead of dodecyl sulphate (This series of alkyl sulphate was kindly supplied by Dr R C Johnson of E I DuPont DeNemours and Co)

Detergent utilization was assayed by non-polar complex formation of detergent with methylene blue via chloroform extraction[4] As a product of enzyme activity, sulphate was measured with barium chloranilate[5]

Bacteria were grown at 37° C in the synthetic medium with sodium dodecyl sulphate as sole carbon and sulphur source The cells were collected by centrifugation, washed with 0 14 M sodium chloride solution and disrupted in a French pressure cell[6] All the detergent-splitting activity remained in the ultra-centrifugal supernatant (110,000g for 90 min) and was not lost after dialysis. The enzyme preparation from cells adapted to SDS released sulphate from decyl- and tetradecyl-sulphate as well as SDS. That the enzyme (or enzymes) is formed adaptively is suggested by the observation that the same strain grown with citrate as carbon source did not yield preparations with these detergent-splitting activities The same conclusion was reached in manometric assays using non-growing cells

With SDS as substrate, the crude enzyme preparation consumed only 0 6 μM oxygen during the release of 11 6 μM sulphate This suggests that oxygen does not participate in the release of sulphate and that the enzyme action is the hydrolysis of the sulphate ester linkage, the other product of this type of reaction would be dodecyl alcohol

When the concentration of SDS exceeded 6 7 × 10^{-3} M, enzyme activity was lost However, addition of bovine serum albumin permitted active hydrolysis of SDS at

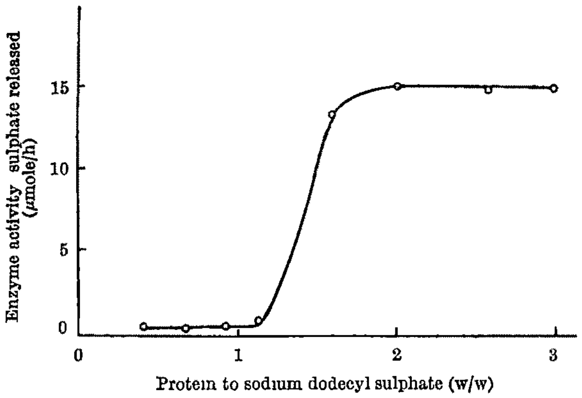

Fig 1 Micromoles of sulphate released in 1 h incubation at 37° C from equal amounts of enzyme in varying ratios of total protein to sodium dodecyl sulphate (SDS) SDS concentration 0 01 M in 0 05 M *tris*-buffer (*p*H 8) containing 0 14 M sodium chloride to a total volume of 1 5 ml

the higher levels of SDS The ratio of total protein to detergent was rather critical, and excess of SDS destroyed the enzyme activity (Fig 1)

Concomitant with the release of sulphate from SDS, protein precipitated from the reaction mixture It is not yet known whether this precipitation resulted from the release of denatured protein from a protein-SDS complex or whether the product of the enzyme reaction, dodecyl alcohol, effected it The latter is a possibility since the alcohol, when added to the system, results in precipitation of protein It is also not known whether the true substrate of the enzyme is protein–SDS complex or free SDS ion equilibrated with such a complex

In this connexion, Putnam and Neurath[7] have demonstrated the formation of protein–SDS complex with mobilities intermediate between those characteristic of the protein and SDS It is also established that SDS forms micelles at concentrations greater than $6–8 \times 10^{-3}$ M, which are in equilibration with the free ions, the latter predominate at low concentration[8] Recently, Bigelow and Sonenberg[9] have demonstrated two different shifts in the ultra-violet spectrum of protein–SDS complex depending on the concentration of detergent The authors suggest that the spectral changes are due to disruption of hydrophobic bonds involving tyrosyl or tryptophanyl residues

The mode of action of SDS concentration below 6×10^{-3} M is under investigation Our bacteria are utilizing the detergent below this level, at which considerable bacteriostatic action is exerted on non-SDS utilizing organisms

Acknowledgement is made to Dr Leonard H Frank for advice and suggestions and to Dr R C Johnson for supplying the alkyl sulphates I thank Dr C W Krusé, and Misses Beverly Jackson and Carole Beach for their help

Solubility in Water of C_1–C_9 Hydrocarbons

THE solubilities in water of C_1–C_8 paraffin and branched-chain paraffin, 4 *cyclo*paraffin, and 5 aromatic hydrocarbons have been determined using a gas-liquid partition chromatographic technique

Because of their relatively high solubility in water, the solubilities of benzene, toluene, xylenes, ethylbenzene, and isopropylbenzene have been determined by several workers[1–7] The solubilities of methane and ethane were determined by Winkler[8] in 1901 and substantiated by the work of Claussen and Polglase[9] in 1952 Claussen and Polglase also determined the solubilities of propane and normal butane However, the only solubility data for C_5 and higher paraffin hydrocarbons were those determined by Fuhner in 1924 He cites values for normal pentane, hexane, heptane, and octane So far as is known, solubilities have not been reported for branched chain paraffin or *cyclo*paraffin hydrocarbons

With the development of the technique of directly injecting water samples into a gas chromatograph[10,11], it is possible to determine the solubilities of hydrocarbons by a different technique from those previously reported Saturated solutions of various hydrocarbons in distilled water were prepared by either shaking vigorously on a reciprocal shaker or stirring several days with a magnetic stirrer Phillips Petroleum Co 99+ per cent purity hydrocarbons were used 20–50 ml of individual liquid hydrocarbons were added to distilled water One atmosphere of the gaseous hydrocarbons was maintained over water during equilibration No attempt was made to maintain the temperature closer than the 25° ± 1 5° C maintained by the air-conditioning system in the laboratory Samples of the hydrocarbon-saturated water were obtained from beneath the hydrocarbon phase A·0 05 ml or 0 10 ml sample of the hydrocarbon-saturated water was directly injected into the gas chromatograph fitted with a suitable fractionator containing 'Ascarite' or 'Drierite' to absorb water The dissolved hydrocarbon released from the water passed into the chromatograph column The concentration of hydrocarbon was determined by measuring the area under the chromatograph peak with a planimeter The hydrogen flame ionization detector was calibrated using known amounts of pure hydrocarbons

Table 1 summarizes the solubilities of the saturated and aromatic hydrocarbons having from 1–9 carbon atoms in water at room temperature The measured solubilities for the aromatic hydrocarbons closely check those reported by previous workers The solubilities of *o*-xylene, ethylbenzene, and isopropylbenzene are somewhat lower than

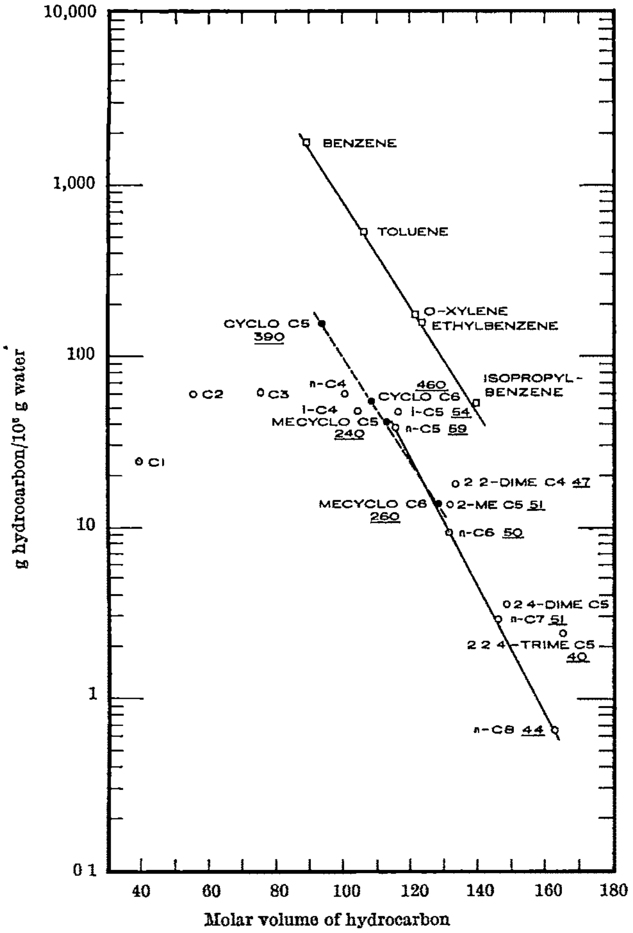

Fig 1 Solubility in water of aromatic □, *cyclo*paraffin ●, and paraffin ○ hydrocarbons as a function of their molar volumes

previously reported The solubilities of methane, ethane, propane, and normal butane are close to the values reported by Winkler, and Claussen and Polglase However, the solubilities found for normal pentane, hexane, heptane, and octane are from 10 to 20 times lower than reported by Fuhner

Lindenberg[12] proposed a relationship between the log of the solubilities of hydrocarbons in water and the molar volume of the hydrocarbons Using solubility data from the literature, he calculated constants for various saturated and aromatic hydrocarbons as well as for chlorinated hydrocarbons If the log of the solubilities of the hydrocarbons in water is plotted against the molar volumes of the hydrocarbons, a straight line is obtained Fig 1 shows such a plot for the saturated and aromatic hydrocarbons The molar volume vs log of the solubility relationship appears to hold for the saturated liquid and aromatic hydrocarbons However, as contrasted to Lindenberg's proposal, all hydrocarbons do not fall on a single line Lindenberg used Fuhner's solubilities for normal C_5, C_6, C_7 and C_8, and, as shown in Table 1, they are much too high The results reported here plot as separate straight lines The aromatic hydrocarbons have considerably higher solubilities for a given molar volume than do the saturated hydrocarbons

The solubilities of the branched-chain paraffin hydrocarbons are higher in all instances than for the normal paraffin hydrocarbons The increased solubilities apparently are not due to a structural feature of the molecules but to the higher vapour pressure (fugacity) of the branched-chain hydrocarbons If the measured solubility of each normal or branched-chain paraffin hydrocarbon with a boiling point higher than 25° C is divided by its vapour pressure in mm mercury at 25° C and multiplied by 760 mm mercury, a predicted solubility at room temperature and 1 atmosphere is obtained The calculated values are shown underlined by the names of the hydrocarbons on Fig 1 The values range from 40 to 59 p p m The lower values appear to be associated with the heavier hydrocarbons The solubilities of ethane, propane, iso- and normal butane range from 49 to 62 p p m Methane with a solubility of only 24 p p m at 1 atmosphere pressure is anomalous With this exception, it appears that to a first approximation the weight of a normal or branched-chain paraffin hydrocarbon which dissolves in water is proportional to the vapour pressure of the hydrocarbon The measurement of hydrocarbon solubilities by the gas chromatographic technique reported here is limited at a concentration of about 0 1 p p m If the solubility data of C_2–C_8 normal and branched-chain hydrocarbons can be extrapolated, the solubility of C_9 and heavier hydrocarbons can be predicted from their vapour pressures

The calculated solubilities at 25° C and 1 atmosphere pressure for the *cyclo*paraffin hydrocarbons are underlined by each *cyclo*paraffin hydrocarbon in Fig 1 The water solubilities of the *cyclo*paraffin hydrocarbons are considerably higher for a given vapour pressure than the normal and branched-chain paraffin hydrocarbons However, the decrease in molar volume for a given carbon number compared with the straight and branched-chain hydrocarbons is such that the *cyclo*paraffin solubilities fall approximately on the line with normal paraffin hydrocarbons However, the dashed line through the 4 *cyclo*paraffin hydrocarbons has a slope parallel with the aromatic hydrocarbons and different from the normal paraffin hydrocarbons

The molar volumes of the aromatic hydrocarbons are less than for *cyclo*paraffin hydrocarbons with the same number of carbon atoms, but the very marked increase in solubility caused by the polar character of the benzene ring more than offsets the decrease in molar volume so that the aromatic hydrocarbons fall on a separate and higher line

The experimental technique and further details of this work will be reported elsewhere

Attenuated Total Reflectance Spectra of Glycyl-L-alanine in Aqueous Solutions

In a recent report[1] the spectra of various dipeptides in the isoionic, basic, and acidic states in water were examined by transmission techniques with 'Irtran-2' cells, and the use of such spectra for structural and identification purposes was discussed A drawback of the method used is that no information can be obtained in areas where water absorbs very strongly This is particularly true around 6µ (~ 1,660 cm^{-1}), where amino-acids and peptides should show characteristic bands The principle of attenuated total reflectance[2] has enabled the examination of even comparatively weak absorption bands and has permitted spectra to be obtained on difficult samples

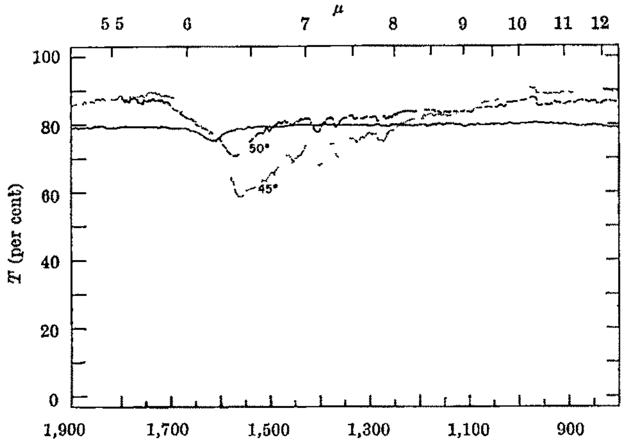

Fig 1 ——, Degree of compensation with two attenuated total reflectance cells containing silver chloride hemicylinders, – – –, the effect of a 50° angle of incidence, , the effect of a 45° angle of incidence

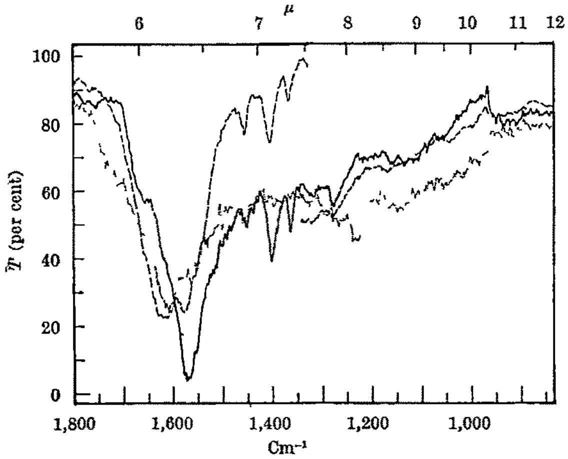

Fig 2 5 per cent (w/v) glycyl-L-alanine, in the isoionic form (——), in the basic form (– – –), and in the acidic form ( )

Spectra of sucrose in water and of whole blood have been shown by manufacturers of infra-red equipment

The purpose of this communication is to show that the use of two attenuated total reflectance accessories allows useful differential spectra to be obtained, particularly in the 6μ region, since the water is not totally absorbing by attenuated total reflectance techniques (With a silver chloride hemicylinder and water in the sample beam versus air in the reference beam, when the baseline is at 90 per cent *T*, the water band has a 50 per cent *T*) The instrument used was a Perkin–Elmer model 421 infra-red spectrophotometer, which was linear in cm^{-1} presentation Both attenuated total reflectance cells were used with silver chloride hemicylinders, the compensating reference cell containing only water

Fig 1 (solid line) demonstrates the degree of compensation and the effect of the angle of incidence (dashed and dotted lines) on band intensity and shape 50° was chosen as the angle of incidence for the runs on glycyl-L-alanine since this angle yields better band shapes at reasonable intensities than does 45° Probably 47° would be still better, but the apparatus has a detent at 50°, which permits locking the optics at this angle

Spectra were recorded for 5 per cent (w/v) aqueous solutions of the dipeptide glycyl-L-alanine in the isoionic, basic, and acidic forms Fig 2 shows these spectra Five times expansion was used on the ordinate scale Significant differences can be seen in the 1,750–1,000 cm^{-1} region Whereas the isoionic and basic forms show what appears to be COO$^-$ absorption (from comparison with transmission spectra[2]) at 1,401 and 1,402 cm^{-1} respectively[3], this band is expectedly missing in the acidic form Another band at 1,364 cm^{-1} in the isoionic form and at 1,368 cm^{-1} in the basic form is missing in the acidic form also, this is also probably a COO$^-$ band[7]

In the region near 1,600 cm^{-1} there are distinct differences between the isoionic, basic, and acidic forms The isoionic form has a band at 1,571 cm^{-1}, which is probably due either to stretching vibrations (CO and CN) arising from the resonating peptide linkage[4] or from NH stretch[5,6] The shoulder at 1,656 cm^{-1} may be associated with the NH_3^+ grouping, but may be associated also with the carbonyl group of the peptide link, which absorbs normally at 1,655 cm^{-1} in the solid-state[7] In the basic form there are bands at 1,579 and 1,620 cm^{-1}, which are probably NH stretching absorptions[7] In the acidic form the band at 1,605 cm^{-1} is probably due to stretching vibrations from the resonating peptide linkage[4] The shoulder at 1,658 cm^{-1} may be associated with the CO of the un-ionized carboxyl group[7] The shoulder at 1,712 cm^{-1} may be the amide-I CO stretch

As with transmission methods, characteristic spectra are obtained, which can be used for identification purposes The advantage of the attenuated total reflectance method lies in the information obtainable in the area where water absorbs strongly by transmission methods

I thank Dr Robert W Hannah, of the Perkin–Elmer Corporation, for recording the spectra and for his advice

Annealing by Compression following Chemical Radiation Damage in Potassium Bromate

RECENTLY it has been shown[1,2] that fragments generated in solid substances by molecular rupture initiated by radiation thermal neutron capture can recombine under the influence of compression These results suggested that other kinds of chemical radiation damage might also be susceptible to annealing by compression At present the only quantitative investigation on annealing of chemical radiation damage in ionic compounds appears to be the thermal annealing investigations on nitrates by Maddock and Mohanty[3–5] In a recent communication Mohanty and Upadhyay[6] have reported that compression of radiation damaged lead nitrate before thermal annealing accelerates the annealing process

Annealing by compression and isothermal annealing investigations have been carried out on radiolysed potassium bromate Boyd *et al* [7] have reported that radiolysis of bromate ion gave bromite, hypobromite, bromide and oxygen gas They also reported, that the oxidizing species in radiolysed alkali metal bromates are susceptible to thermal annealing, but no attempt was made to determine the annealing kinetics The experiments were conducted on a sample of potassium bromate crystals sieved to between 80–100 mesh The crystals were irradiated to a dose of about 50 Mrads with 2-MeV electrons The annealing by compression was carried out using the Tuttle-type of pressure bomb

Table 1 gives the results of annealing by compression at 20° and 135° The samples were compressed in 2 min The experiments at 135° were carried out allowing the sample to reach the temperature before the pressure was applied The equilibrium temperature was obtained after 10 min The 'oxidizing power' representing the oxidizing fragments produced by radiolysis (bromite, hypobromite, etc) was determined by an arsenite–iodide titration The total bromide content representing the total non-bromate bromine produced by radiolysis was determined by a micro-potentiometrical titration with silver nitrate after the oxidizing fragments were reduced by arsenite[7]

Table 1

Treatment	Temperature (°)	'Oxidizing power' (m equiv mole^{-1})	Direct bromide content (m mole Br^{-} mole^{-1})	Total bromide content (m mole Br^{-1} mole^{-1})
None	20	17 1	7 2	12 2
Compressed, 1,000 atm	20	15 9	7 4	12 1
Compressed, 2,000 atm	20	14 3	7 7	12 0
Heated, 10 min	135	16 4	7 3	12 1
Heated and compressed, 10 min, 1,000 atm	135	10 7	8 0	11 3
Heated and compressed, 10 min, 2,000 atm	135	7 1	8 6	10 7

The results show that the chemical radiation damage can be annealed by compression The oxidizing fragments forming hypobromite and bromite on solution are annealed to bromate and bromide forming fragments by compression of the material The isothermal annealing experiments show that these reactions occur by heating the material, too The possibility that the observed effects by thermal annealing arose from aerial oxidation was excluded by showing that virtually the same annealing occurred whether the crystals were heated in air or *in vacuo* Combinations of compression and thermal annealing show that the compression produces two different effects a rapid annealing directly induced by the application of pressure, and the second an acceleration of the thermal annealing processes

I thank Dr J D C MacConnell, Department of Mineralogy, Cambridge, for arranging the compressions

Viscosity - Molecular Weight Relationship for Polyvinyl Chloride

THE expression $[\eta]=KM^a$, where $[\eta]$ is the intrinsic viscosity, M, the molecular weight, and K and a are constants for a given polymer-solvent system, is commonly used to relate $[\eta]$ and the molecular weight of the polymer Values of K and a for polyvinyl chloride-solvent systems often show considerable variations for the same solvent Table 1 gives values obtained for *cyclo*hexanone as solvent with the temperature, type of molecular weight and whether unfractionated polymers or fractions were used in the determination of K and a

Table 1 VALUES OF K AND a FOR POLYVINYL CHLORIDE–*Cyclo*HEXANONE

Author(s)	K	a	Comments	Ref
Hengstenberg	$1\ 95=10^{-4}$	0 79	25°, $\overline{M}_n$, unfractionated	1
Breitenbach *et al*	$1\ 16=10^{-4}$	0 85	20°, $\overline{M}_n$, unfractionated	2
Mencık	$2\ 04=10^{-3}$	0 56	25°, $\overline{M}_n$, fractions	3
Danusso *et al*	$2\ 4\ =10^{-4}$	0 77	25°, $\overline{M}_n$, unfractionated	4
Ciampa and Schwindt	$1\ 1\ =10^{-5}$	1 0	25°, $\overline{M}_w$, unfractionated	5
Bier and Kramer	$1\ 13=10^{-3}$	0 63	25°, $\overline{M}_n$, fractions	6

Endo[7] fractionated five different commercial samples and obtained values of a varying from 0 72 to 1 08 from values of $[\eta]$ and $\overline{M}_n$ in *cyclo*hexanone at 30°

We have fractionated a commercial polyvinyl chloride prepared by emulsion polymerization (Breon 121) The polymer was first extracted with hot ethanol to remove emulsifying agent and then fractionated by stepwise addition of 80/20 by volume tetrahydrofuran/water mixture to a 1 per cent solution in tetrahydrofuran Five primary fractions were each refractionated to give a total of fifteen sub-fractions of which six were used in further work Number average molecular weights $\overline{M}_n$ of these were determined osmotically in *cyclo*hexanone at 25 ± 0 01° using Pinner–Stabin osmometers[8] statically The membranes used were of cellulose, treated with 5 per cent aqueous caustic soda before washing in water and conditioning to *cyclo*hexanone This treatment was found to prevent diffusion of low molecular weight material which occurred when untreated membranes were used with solutions of the unfractionated polymer Plots of π/c, where π is the osmotic pressure and c the concentration, against c were slightly curved and plots of $(\pi/c)^{\frac{1}{2}}$ against c were extrapolated to zero concentration to obtain values of $\overline{M}_n$ Weight average molecular weights $\overline{M}_w$ in *cyclo*hexanone at 25° ± 0 01° were determined using a Brice-Phoenix light scattering photometer The refractive index increment was 0 0867 Intrinsic viscosities in *cyclo*hexanone at 25° ± 0 01° were obtained by use of suspended level capillary viscometers Flow times were such as to prevent shear effects and kinetic energy corrections were made where applicable The *cyclo*hexanone was purified and fractionally distilled just before use All solutions were heated for 1 h at 80° and then cooled before being used This procedure, also used by Mencık[3], is necessary to break down rapidly aggregates which, if of high molecular weight material, break down very slowly at 25°

Fig 1 shows logarithmic plots of $[\eta]$ against $\overline{M}_n$ and $\overline{M}_w$ Values of K and a, obtained from these by the method of least squares, are

$$\overline{M}_n \quad K=2\ 08\times10^{-3}\ ,\ a=0\ 56\pm0\ 02$$
$$\overline{M}_w \quad K=1\ 74\times10^{-3}\ ,\ a=0\ 55\pm0\ 02$$

The values of a are in good agreement and those of K and a for $\overline{M}_n$ are in excellent agreement with those of Mencık[3] Values of $\overline{M}_w/\overline{M}_n$ for the fractions are all about 2. The fact that the plots are essentially parallel suggests that the fractions not only have similar values of $\overline{M}_w/\overline{M}_n$ but also have similar molecular weight distribution[9]

Reasons for the values of K and a given by other workers are not entirely clear Diffusion of low molecular weight material in osmotic measurements or the presence of aggregates not removed by prior heating might lead to higher values of the exponent a Different values of K and a could also result from the use of unfractionated polymers with different molecular weight distributions Lower values of a tend to be obtained when fractions are used

It is also possible that polyvinyl chloride prepared by emulsion polymerization differs in chain structure from that obtained by other methods Hengstenberg[1], Mencık[3] and Bier and Kramer[6] used emulsion polymers Other workers[2,4,5,7] used polymers prepared by bulk, solution and suspended polymerization although Danusso *et al* [4]

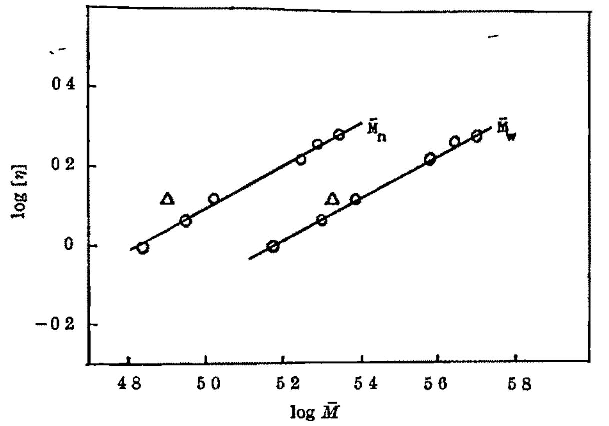

Fig 1 Plots of log [η] versus log $\bar{M}_n$ and log $\bar{M}_w$ for polyvinyl chloride–*cyclo*hexanone at 25°C O, Fractions, Δ, unfractionated polymer

included emulsion polymers Hengstenberg's value apart, values of *a* obtained using emulsion polymers are less than those obtained by use of polymers prepared by other methods It seems probable that this is a consequence of chain branching Bier and Kramer state that their value of 0 63 for *a* refers to branched material Peterlin[10] has shown that appreciable branching of polyvinyl chloride may occur and lead to formation of aggregates Emulsion polymers are generally of higher molecular weight than those obtained by other methods and may be more highly branched

Emulsion polymers of vinyl chloride may generally be more branched than suspension polymers apart from any specific influence of higher molecular weight Polyvinyl chloride is virtually insoluble in vinyl chloride but vinyl chloride is soluble in the polymer to the extent of about 30 per cent This means that during polymerization the effective monomer concentration is lower and the effective polymer concentration higher in emulsion polymer particles than in suspension polymer particles Chain branching is therefore more likely in the former and it has been suggested[11] that the incidence of branching may be three or more times greater in emulsion polymers of vinyl chloride than in polymers obtained by suspension polymerization

It would thus seem to be likely that the low values obtained for the exponent *a* reflect chain branching The values of the polymer–solvent interaction parameter χ_1 was found, in the present work, to be 0 22 This relatively low value suggests that *cyclo*hexanone is a thermodynamically good solvent for polyvinyl chloride and a higher value of the exponent *a* might be expected if the chains were linear

We thank Mr J Benton, of British Geon, Ltd, for useful advice, especially on chain branching of emulsion polymers, and British Geon, Ltd., for the supply of materials

Action of Bovine and Human Pancreatic Phospholipase *A* on Lipoprotein-bound Phospholipids

IN previous reports from our laboratory some characteristics of the *in vitro* and *in vivo* activity of snake venom phospholipase *A* were described The enzyme was found to split lipoprotein-bound phospholipids present in egg yolk and serum at a higher rate than in their total lipid extracts or than purified ovolecithin[1] Intravenous administration of snake venom phospholipase *A* into rabbits produced a rapid and marked decrease in plasma lecithin, an increase in plasma lysolecithin and attachment of lysolecithin to the red blood cells with ensuing red cell sphering[2] In the work recorded here we investigated whether phospholipase *A* preparations from sources other than snake venom had similar action Phospholipase *A* preparations from both human and bovine pancreas were obtained according to the method of Rimon and Schapiro[3] A standard suspension of the enzymes containing 10 mg protein/ml in 0 04 M veronal buffer *p*H 7 6 was used

The human and bovine phospholipase *A* preparations were acted on egg yolk and plasma, on total lipid extracts of egg yolk and plasma, and on purified lecithin The total lipid extracts and the purified lecithin were prepared as described previously[1] Both the egg yolk and the egg yolk lipid extracts were 5-fold diluted in 0 04 M veronal buffer *p*H 7 6, and the purified lecithin was suspended in the buffer to a concentration of 10 mg/ml The enzymatic splitting of the substrates was followed by free fatty acid release according to the method of Dole[4] The comparative splitting of plasma lipid extract by the two enzyme preparations was followed by the decrease in lecithin content Phospholipids were extracted, chromatographed on silicic acid impregnated paper, and the lecithin spot analysed for lipid phosphorus as described by Klibansky[2]

As seen in Tables 1 and 2, both human and bovine pancreatic phospholipase *A* preparations split the lipoprotein-bound phospholipids at higher rate than the phospholipids in the lipid extracts or than purified lecithin The human pancreatic phospholipase preparation showed higher activity than the bovine on all substrates tested

Table 1 COMPARATIVE ASSAY OF FREE FATTY ACIDS RELEASED IN THE COURSE OF ACTION OF HUMAN AND BOVINE PANCREATIC PHOSPHOLIPASE *A* ON VARIOUS SUBSTRATES

Pancreatic phospholipase *A*	Substrates	Free fatty acids released (µequiv /ml) 10 min	20 min	40 min	60 min
Human	Egg yolk	3 31	6 12	7 74	9 07
Human	Egg yolk lipid extract	2 12	4 62	5 50	5 50
Human	Lecithin	0 47	1 52	2 15	2 32
Bovine	Egg yolk	1 01	1 92	2 99	3 79
Bovine	Egg yolk lipid extract	0 41	0 76	0 76	0 85
Bovine	Lecithin	0	0	0	0

Incubation system 0 5 ml substrate, 0 5 ml enzyme suspension, 0 1 ml ether, 0 05 ml 5 mM calcium chloride, temperature 37° C

Table 2 COMPARATIVE SPLITTING OF LECITHIN IN PLASMA AND PLASMA LIPID EXTRACT BY HUMAN AND BOVINE PANCREATIC PHOSPHOLIPASE *A*

Pancreatic phospholipase *A*	Substrate	Lecithin phosphorus (mg %) Zero-time	After 1 h incubation	Per cent lecithin split
Human	Plasma	2 60	0	100
Human	Plasma lipid extract	2 16	1 25	42
Bovine	Plasma	3 36	1 83	54
Bovine	Plasma lipid extract	3 12	2 50	20

Incubation system 1 ml substrate, 1 ml enzyme suspension, 0 1 ml ether, 0 05 ml 5 mM calcium chloride, temperature, 37° C

Pancreatic phospholipase *A* preparations were injected into the ear vein of rabbits kept on a regular diet After various time-intervals blood was withdrawn by heart puncture for determination of plasma lecithin and lysolecithin by means of silicic acid paper chromatography[2] Blood samples from the ear vein were examined for red blood cell shape The bovine pancreatic phospholipase preparation was administered in two portions, each

Table 3 CHANGE IN PLASMA LECITHIN AND LYSOLECITHIN AND IN RED CELL SHAPE FOLLOWING INTRAVENOUS ADMINISTRATION OF BOVINE PANCREATIC PHOSPHOLIPASE *A* IN THE RABBIT

Time of blood collection	Lecithin phosphorus (mg %)	Lysolecithin phosphorus (mg %)	Red cell shape
Before injection	3 10	0 41	Bidiscoid
20 min after 1st injection	2 22	0 60	Coarsely crenated spheres
20 min after 2nd injection	1 61	0 41	Coarsely crenated spheres

Second injection 45 min after first injection

containing 50 mg protein suspended in 5 ml veronal buffer, at 45-min interval As seen in Table 3, plasma lecithin decreased during a 65-min observation period, while lysolecithin first increased and afterwards reached the pre-injection level The red blood cells became coarsely crenated spheres and retained this shape during the observation period In contradistinction to the well-tolerated bovine pancreatic phospholipase preparation, intravenous administration into rabbits of human pancreatic phospholipase preparation, in an amount containing 50 mg protein, caused rapid death Using smaller amounts, the animals survived but no red cell shape change appeared, pointing to a lower degree of plasma lecithin splitting The cause of the toxicity of the human pancreatic phospholipase *A* preparation has not been elucidated.

These results are in agreement with the previously reported results concerning the action of snake venom phospholipase *A*[1,2], both as to the higher rate of splitting of lipoprotein-bound phospholipids *in vitro* and the conversion of plasma lecithin to lysolecithin with associated red cell sphering *in vivo* A similar action *in vivo* has been described for bee venom phospholipase *A* by Habermann and Krusche[5] It is evident that lipoprotein-bound phospholipids are readily attacked, both *in vitro* and *in vivo*, by phospholipase *A* obtained from diverse sources

Kinetics of Collagen Synthesis by Established Mammalian Cell Lines

IT was recently reported that certain established lines of mouse fibroblasts, capable of indefinite propagation in culture[1], were able to synthesize appreciable quantities of collagen[2] The collagen appeared as extracellular fibres of characteristic periodicity between cells growing in multiple layers on the surface of a Petri dish This communication examines the temporal relationship between cell growth and the expression of this differentiated function

A trypsinized suspension containing 5 × 10^4 log phase cells of established line *3T6* was inoculated into 50 mm plastic Petri dishes The cells attached to the surface and began to grow within approximately 12 h They then grew exponentially for about 3 days with a mean doubling time of 13 h (Fig 1*A*) Thereafter, the growth rate declined rapidly, and the culture soon reached a saturation density of about 9 × 10^6 cells, no further increase in cell number occurred for the 24 days of this experiment, although the supernatant liquid medium was changed three times weekly Throughout this period the majority of the cells remained viable, trypsinization producing a suspension of healthy-appearing cells with a plating efficiency of 80 per cent on X-irradiated feeder cells

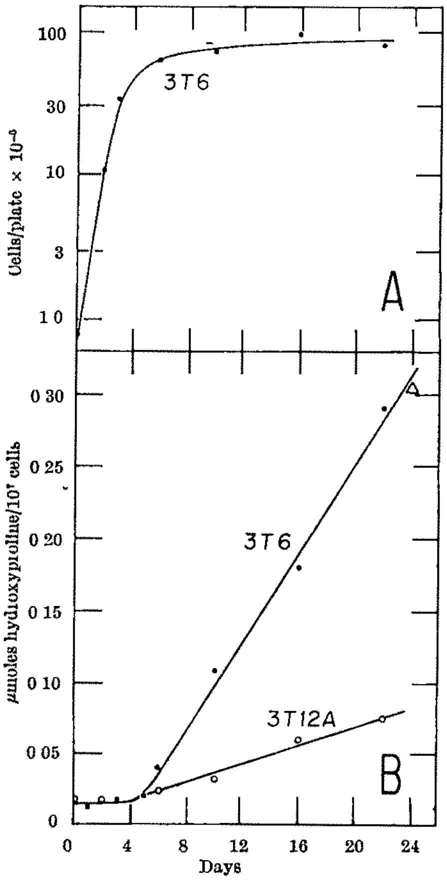

Fig 1 *A*, Growth curve of line *3T6* Day 0 is the day following inoculation *B*, Hydroxyproline formation by established lines *3T6* and *3T12A* Δ indicates determination of hydroxyproline on *3T6* cell layer after isolation of the pure amino-acid by chromatography

The synthesis of collagen by the cells was examined by hydroxyproline determinations[3] on the washed and hydrolysed cell layer Fig 1*B* (top curve) shows the quantity of hydroxyproline found in the cell layer at various times Through the exponential growth phase, low constant values were obtained, equivalent to 0 017 μmoles of hydroxyproline per 10^7 cells As the method used is not absolutely specific for hydroxyproline, a hydrolysate of 2 × 10^6 log phase cells was subjected to column chromatography and the eluate analysed for the pure amino-acid Since none could be detected (less than 0 0003 μmoles per 10^7 cells), the low constant values of days 0–4 in Fig 1*B* do not represent hydroxyproline but rather non-specific colour formation

At day 5, when the number of cells approached a maximum, hydroxyproline appeared in the cell layer and increased linearly with time throughout the remainder of the experiment The constant rate of synthesis during this time for line *3T6* was approximately 0 016 μmoles of hydroxyproline per 10^7 cells per day Chromatographic isolation of hydroxyproline from a replicate stationary phase culture on day 24 gave a value of 0 30 μmoles per 10^7 cells, in good agreement with determinations made directly on the hydrolysate (see Fig 1*B*) Another established line, *3T12A*, reached a similar saturation density and then began to produce collagen, though at a lower rate (0 005 μmoles hydroxyproline/10^7 cells/day) It is concluded that collagen does not begin to accumulate in the cell layer until the period of rapid growth is completed

This conclusion is supported by electron microscopic data from thin sections of replicate cultures at different times. Log phase cultures did not contain extracellular fibrils. Stationary phase cultures, beginning at day 5, showed abundant extracellular fibrils, which later developed the banding typical of collagen. Stationary phase cells showed the cytodifferentiation of protein-secreting cells.

These experiments did not rule out the possibility of liberation of soluble collagen into the liquid medium by log phase cells. Cultures in log and stationary phases were therefore incubated for 12 h with proline labelled with carbon-14, the cold trichloroacetic acid-insoluble protein of the cells and medium of each culture was then hydrolysed. Carrier hydroxyproline was added to the hydrolysates and re-isolated chromatographically. The log phase cells and medium together contained only 6 per cent of the hydroxyproline radioactivity of the saturation density cultures.

During the establishment of line 3*T*6, the cells were transferred regularly every 3 days at an inoculum size of 6×10^5 cells, for about 100 cell generations. Under these conditions, the cells never reached a stationary phase and therefore could not have synthesized appreciable collagen. Nevertheless, this differentiated cell function was not lost during the period when it could not be expressed. The synthesis of collagen by these cell lines offers a clear demonstration of the often stated antagonism between growth and differentiation in mammalian systems. The nature of the changes which result in the arrest of cell division and the onset of collagen synthesis is the object of continuing investigation.

Ultra-violet Photolysis of Unsaturated Fatty Acids in Relation to the Thiobarbituric Acid Test

A CHARACTERISTIC pink coloration was observed by Kohn and Liversedge[1] after heating tissue suspensions with aqueous thiobarbituric acid (TBA). Colour formation was attributed to reaction of unknown oxidation products of unsaturated fatty acids[2]. The principal TBA-reactive substance is considered to be malonaldehyde[3,4]. However, the means of formation of malonaldehyde is unknown. Inasmuch as ultra-violet irradiation of unsaturated fatty acids had been used to produce TBA-reactive products[5], investigation of the radiation-induced oxidation was conducted in this work in an attempt to clarify the basis of the TBA test.

Five g of linolenic acid (Hormel Foundation, Austin, Minn.) were placed in the bottom of a Petri dish (80 mm diam.) and were irradiated for 18 h by placing two unfiltered Mineralight lamps (Ultra-Violet Products, Inc., South Pasadena, Calif., model *SL* 2537) on the dish. The lamps and dish were covered with aluminium foil and linen cloth. The ambient temperature below the foil was 40°–45° C.

The viscous yellow product was transferred, with four 10-ml water washings, into a 250-ml separatory funnel. Thirty ml of water were added, and the mixture was shaken vigorously for 30 sec. After 15 min, the opalescent lower phase of approximately 50 ml was collected. The remaining mixture was extracted three times with 50-ml aliquots of water. The aqueous extracts were combined and filtered, with gentle suction, through three glass fibre disks (H. Reeve Angel and Co., Ltd., No. 934-*AH*, 2.1-cm diam.) in a Gooch crucible mounted on a filter flask. The filtration was repeated several times with fresh disks until the extract was water-clear. The disks were discarded. The filtrate was diluted to 250 ml with water and washed by shaking successively with 60 ml of hexane and 60 ml of carbon tetrachloride. The washings did not give rise to a pink chromogen in the TBA test of Waravdekar and Saslaw[6] and were discarded. The aqueous phase was concentrated by lyophilization until about 10 ml remained. After thawing, aliquots were diluted with water and ultra-violet absorption spectra were recorded. The diluted aliquots were also assayed for malonaldehyde[6,7] by heating during 20 min with the TBA reagent. Results were expressed in absorbance units at 532 mμ and 225 mμ and were termed the activity (TBA or ultra-violet) in the particular test.

Fig. 1 shows the spectra obtained with extracts prepared in like manner from irradiated and non-irradiated linolenic acid. Irradiation resulted in the appearance of pronounced absorption at 225 mμ. Inasmuch as the hydroperoxides of unsaturated fatty acids absorb maximally at about 234 mμ and malonaldehyde absorbs maximally at 245 mμ[8], the predominant spectral feature resulting from the irradiation process may not be ascribed to the presence of either material. The TBA activity of the extract of irradiated and non-irradiated lipid was 87.5 and 0.5 units respectively. When calculated on the basis of malonaldehyde, these values corresponded to 124.0 and 0.7 μg respectively. The spectral characteristics of the chromogen solutions in the TBA test differed from those observed with malonaldehyde only in displaying slight absorption at 450–480 mμ.

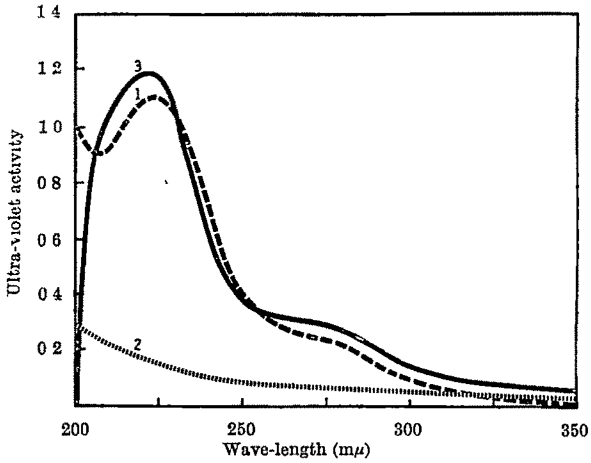

Fig. 1. Absorption spectra of diluted extracts. 1, from irradiated linolenic acid; 2, from non-irradiated linolenic acid; 3, ethanolic extract obtained from chromatogram.
Spectra were determined for a 10-mm light path with a Perkin-Elmer 202 spectrophotometer and a water blank or ethanol blank.

To investigate the nature of the TBA-reactive material, counter-current distribution studies were conducted with a glass train of 20 cells (E-C Apparatus Co., Philadelphia). A portion of the extract of irradiated linolenic acid was subjected to 19 transfers in an *n*-butanol–ethylenediamine solvent system (*p*H of aqueous phase = 8.3). Approximately 48 per cent of the TBA activity was recovered in the aqueous phase. The results (Fig. 2) revealed the presence of two TBA-reactive components. Neither component could be distinguished from malonaldehyde on the basis of the spectra obtained in the TBA test except for slight absorption in the region of 450–480 mμ. Tubes 2–4 were pooled and, in comparison with fresh aqueous phase, were found to display a pronounced absorption maximum at 225 mμ[9]. The minor component (pooled tubes 10–12) exhibited a slight absorption maximum at 220–225 mμ.

Similar results were obtained with an extract of irradiated arachidonic acid.

Extracts of irradiated methyl linolenate and irradiated methyl arachidonate were also prepared. All extracts were fractionated by using thin-layer chromatograms. Glass plates (20 cm × 20 cm) coated with a 300-μ layer of 'Camag-*D5*' silica-gel (Fluka AG, Buchs SG, Switzerland) were activated at 105° C for 3 h. The plates were spotted with 50–100 μl. of each extract. Malonaldehyde, obtained by distillation from the bisulphite addition compound[8], was spotted at references sites. A solvent mixture (*n*-butanol/dichloromethane/water, 20 : 4 : 1) was allowed to ascend along the plates during 4 h. The plates were brought nearly to dryness in a hood, sprayed with the TBA reagent, and heated at 65°–70° C for 5 min. With each extract, one yellow spot ($R_F = 0{\cdot}8$) and two pink spots ($R_F = 0{\cdot}9$ and 0·6) were obtained (Fig. 3). Malonaldehyde migrated only slightly and with considerable tailing ($R_F = 0{\cdot}25$). No proof of its presence in the extracts was evident. In further investigations with an extract of irradiated linolenic acid, parallel unsprayed regions were scraped from the chromatogram and were extracted with ethanol. The ethanolic extract corresponding to the leading spot possessed 10 times the TBA activity of the hindmost TBA-reactive region and also contained most of the ultra-violet activity of the extract. Sixty per cent of the TBA activity was recovered.

Consequently, by using different procedures of fractionation (counter-current distribution and thin-layer chromatography), two TBA-reactive components were detected. Less than 0·3 μg of malonaldehyde may be visualized on the chromatogram. Because products other than malonaldehyde account for the major portion of the TBA activity, it is considered that malonaldehyde is not present in the extracts.

It was also noted that, unlike malonaldehyde, the extracts of the irradiated lipids failed to produce colour with the Claisen reagent[10] despite the existence of an adequate level of malonaldehyde as ascertained with the TBA test.

The ultra-violet absorption spectra of all extracts were similar. With the extract of irradiated linolenic acid, the ethanolic extract of the predominant TBA-reactive site on the chromatogram exhibited a peak at about 225 mμ (Fig. 1). Absorption in the far ultra-violet region was considerably less than was observed for the unfractionated extract.

Association of the ultra-violet activity with the major portion of the TBA activity in each procedure of fractionation supports the tentative assignment of both activities to one compound. Preliminary studies have implicated an unsaturated carbonyl component.

Extract: 1, malonaldehyde ; 2, linolenic acid ; 3, arachidonic acid ; 4, methyl arachidonate ; 5, methyl linolenate

Fränz and Cole[11] recently separated several 'TBA-positive' compounds from irradiated methyl linolenate by gas chromatography. The presence of several TBA-reactive compounds is of interest in view of the prevailing belief that malonaldehyde is responsible for the characteristic test.

Uptake of Particulate Matter within the Thymus of Adult and New-born Mice

In 1961 Marshall and White[1] proposed the presence of a 'blood thymus barrier' to explain the failure of the thymus to react to antigenic stimuli given by ordinary routes of administration. Furthermore, because of the exclusion of the thymus from normal auto-antigenic stimuli it was suggested by these authors that the thymus might be the proliferation site of 'forbidden clones' of lymphocytes[2].

This investigation was undertaken to examine the uptake by the adult and new-born mouse thymus of materials ordinarily used to study the reticuloendothelial system, and thereby evaluate the 'blood thymic barrier'.

Adult (about 25 g) mice of *Cf* and *CFW** (Carworth Farms, New City, N.Y.) strain, and new-born mice of *B6AF*1 and *LAF*$_1$, Roscoe B. Jackson Memorial Laboratories, Bar Harbor, Maine, strain were used. The following materials were administered: trypan blue (National Aniline Division, Allied Chemical Corp.), 'Thorotrast' (Testagar and Co., Inc., Detroit, Mich.), carbon 'Pelikan' ink (Gunther Wagner, Germany), and fluorescein-labelled human albumin, egg albumin and human γ-globulin. Coupling to fluorescein isothiocyanate was performed according to the method of Rinderknecht[3]. The coupled proteins were then heat denatured[4]. The dosages and route of administration of these materials are shown in Table 1.

Table 1

Substance injected	Route	Dose	Time of killing after administration (h)
		Adult mice	
Trypan blue	Subcutaneous	2% in H_2O 0·3 c.c./mouse	24–72
'Thorotrast' (24%)	Intravenous	0·2 c.c./mouse	6–8
Carbon 'Pelikan' ink	Intravenous	0·65% suspension 0·1 c.c./mouse	6–8
Fluorescein-labelled proteins (heat denatured)	Intravenous and intraperitoneal	0·6 c.c. of 0·1% solution, half-dose given intravenous; other half given intraperitoneal	6
		New-born mice	
Trypan blue	Subcutaneous	0·05 c.c. of 0·7% solution in H_2O/mouse	24
'Thorotrast' (24%)	Intravenous*	Dilution 1 : 5, 0·05 intravenous	6
Carbon 'Pelikan' ink	Intravenous*	0·05% solution 0·05 c.c./mouse	6
Fluorescein-labelled proteins (heat denatured)	Intravenous*	0·1 % solution 0·05 c.c./mouse	6

* Retro-orbital vein.

Tissue sections were prepared according to standard methods of alcohol dehydration and paraffin embedding. Sections were cut at 6μ and were stained with alcoholic eosin; at no time were they exposed to concentrations of alcohol below 80 per cent. The tissues containing the fluorescein-labelled proteins were processed in the cold according to the technique of Sainte-Marie[5], and were examined with a Leitz ultra-violet microscope.

Particulate matter within or associated with blood vessels or in fibrous septum and connective tissue was scored as negative. Only those thymuses showing particulate material widely distributed in many cells (macrophages) of the thymic parenchyma were considered positive. In each animal the liver and thymus were always examined. The spleen and lymph nodes were examined in fewer animals.

The results are shown in Table 2. The numerator indicates the number of organs showing uptake; the denominator shows the total number of organs examined. With two exceptions, the thymuses stained only in those animals with stained livers. Cells containing particulate material were present both in cortex and medulla. In adult mice trypan blue was found in the thymus in almost half the cases. 'Thorotrast' and carbon were found in the thymus infrequently. Denatured fluorescein-labelled proteins were never found in the thymus. In new-born mice trypan blue was infrequently found in the thymus. However, here the liver also showed poor uptake. In contrast, thorotrast and carbon were found frequently in the thymus (Fig. 1). Finally, fluoresceinated proteins were found infrequently in the thymus.

Most investigators have indicated that the thymus responds poorly if at all to antigen given to an animal at a site distant from the thymus[6]. However, Stoner *et al.*[7] have found that thymus can produce antibody, as demonstrated by pre-immunized intra-ocular thymus grafts functioning in irradiated mice. Marshall and White[1] have shown that antigen injected directly into the thymus of rats and guinea pigs does stimulate plasma cell production of specific antibody; they therefore proposed the concept of a 'blood thymus barrier' to explain the failure of thymic immunological activity.

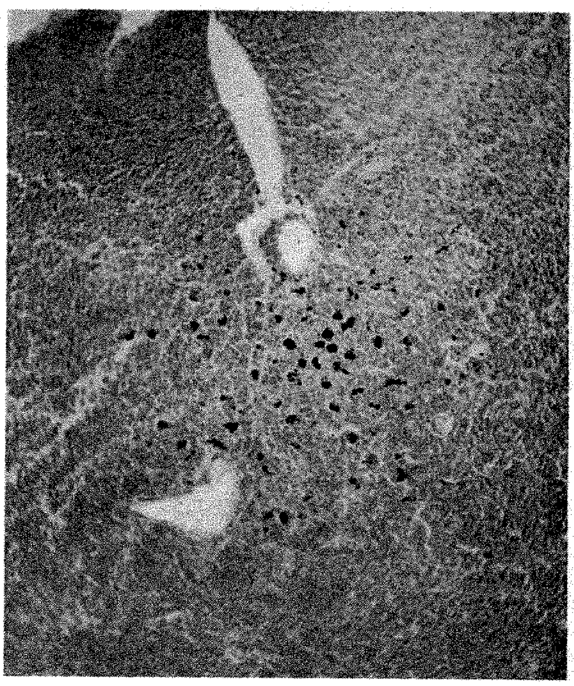

Fig. 1. Thymus of new-born mouse showing macrophages containing carbon. Localization is mainly in medulla

There has been no recent large-scale systematic investigation of the entry of materials into the thymus. However, early investigations of Kaplan and Coons[8] using pneumococcal polysaccharide indicated that this material reached the thymus in large amounts. Marshall and White[1], using a few animals, indicated that trypan blue and pneumococcal polysaccharide reached the thymus only rarely. Svet-Moldavsky *et al.*[9] have recently reported that foot-pad and subcutaneous injection of Freund's

adjuvant lead to the formation of follicular structures and plasma cells within the thymus, and have suggested that Freund's adjuvant may reach the thymus after injection at a distant site.

The present investigation indicates that trypan blue reaches the adult thymus easily, and that 'Thorotrast' and carbon are frequently found in the new-born mouse thymus. The reason that the thymus does not respond to ordinarily administered antigenic stimuli may be more complex than failure of antigen to reach thymic tissue.

The fact that the thymus of the new-born appears more permeable to particulate material than the adult thymus is of interest and deserves further investigation.

We thank Dr. Theodore Spaet for his advice.

Toxicity and Fluorescence Properties of the Aflatoxins

THE isolation, characterization and some of the properties of four closely related components of aflatoxin, the mixture of toxic metabolites produced by certain strains of *Aspergillus flavus*, have been described previously[1]. These components were named aflatoxins B_1, B_2, G_1 and G_2. Structural formulæ have been proposed for aflatoxins B_1 and G_1 (ref. 2) and the relationships between these compounds and B_2 and G_2 have been established[1,3], the double bond in the terminal dihydrofuran ring in the first two components having become hydrogenated in the others.

This communication is concerned with the relative intensities of fluorescence of the four major components and their acute toxicities when administered to day-old ducklings.

The peak fluorescence intensities of the aflatoxins in methanol solution were measured in arbitrary units on an Aminco-Bowman spectrofluorimeter. Freshly re-crystallized material and freshly prepared solutions (0·2 μg/ml.) were used. This concentration was in the range where a linear relationship existed between concentration and fluorescence intensity. The relative fluorescence intensities[4] KQ of the four components were obtained by comparing the intensity of the solutions (calculated to 1 μg/ml.) with that of a solution of quinine sulphate of the same concentration in 0·1 N sulphuric acid when excited at 350 mμ and measured at 450 mμ. The KQ values are recorded in Table 1. In the case of aflatoxin B_1 KQ was found to rise to 1·5 after 3 h and then fall again to 0·5 after a further 17 h.

Table 1. FLUORESCENCE PROPERTIES OF THE AFLATOXINS

Aflatoxin	$\lambda_{\text{exitation max.}}$ (mμ)	$\lambda_{\text{emission max.}}$ (mμ)	KQ*
B_1	365	425	0·5
B_2	365	425	4
G_1	365	450	2·5
G_2	365	450	6·5

$$* \; KQ = \frac{\text{fluorescence intensity of aflatoxin solution}}{\text{fluorescence intensity of standard quinine sulphate solution} \times \text{concentration of aflatoxin solution } (\mu\text{g/ml.})}$$

The acute toxicity of each compound was determined by biological assay using day-old Khaki Campbell ducklings (average weight 38 g). Various dose-levels of each compound dissolved in dimethylformamide were administered to groups of 8 fasting ducklings. Each bird received 0·1 ml. by tube into the gizzard and mortality was recorded for 6 days after administration. Histopathological examinations of the livers were carried out to determine whether death was due to aflatoxin poisoning. The four compounds were found to produce similar histopathological hepatic changes which were indistinguishable from the lesions seen in field cases of aflatoxicosis in ducklings[5]. The LD_{50} value for each compound was calculated on the basis of 50 g body-weight day-old duckling. Under these conditions the LD_{50} for B_1 (3 assays) was 18·2 μg (5 per cent fiduciary limits 14·0–23·8 μg), for B_2 (single assay) 84·8 μg (5 per cent limits 65–110 μg), for G_1 (2 assays) 39·2 μg (5 per cent limits 27·1–56·7 μg) and for G_2 (2 assays) 172·5 μg (5 per cent limits 158–188 μg). No deaths occurred in control groups dosed with 0·1 ml. dimethylformamide alone nor were any hepatic changes observed on histopathological examination.

From these results it can be seen that reduction of the isolated double bond in the terminal dihydrofuran ring of B_1 and G_1 to give B_2 and G_2, respectively, lowers the toxicity. The reduction in activity is very similar in both series, the ratio of the LD_{50} values of $B_1 : B_2$ being 1 : 4·66 and for $G_1 : G_2$ being 1 : 4·40. Expansion of the pentenone ring in the B series to give a second lactone ring in the G series also reduces the toxicity; the ratio of the LD_{50} values of $B_1 : G_1$ is 1 : 2·15 and of $B_2 : G_2$ is 1 : 2·03.

The pronounced difference between the fluorescence intensities of the four aflatoxins together with the difference in their biological activities makes it difficult to relate the toxicity of a mixture of these compounds to its fluorescence intensity.

Accordingly, if fluorescence is to be used as a precise indication of toxicity it is desirable that each constituent should be separated and individually determined. Moreover, the measurements of fluorescence should be made under carefully controlled conditions.

We thank Mr. A. B. Wood for fluorescence measurements, Miss C. N. Hebert for statistical analyses and Mrs. M. Harrison for assistance.

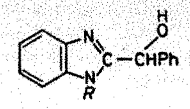
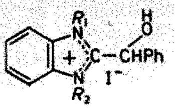
2-(α-Hydroxybenzyl)-benzimidazolium Salts and their Influence on Cultured Cells infected with Poliovirus

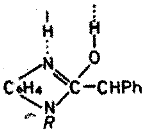
1-ALKYL-2-(α-HYDROXYBENZYL)-BENZIMIDAZOLES (I) give a high degree of protection against the cell degeneration which follows infection of tissue cultures with poliovirus (types 1, 2 and 3)[1]. The action of corresponding quaternary salts (II) is of considerable interest in view of: (*a*) the much greater solubility of these compounds in water; (*b*) the introduction of the positive charge; (*c*) the removal of the type of hydrogen-bonding (III) or metal-chelating (IV) propensities that might (for example, by allowing attachment to protein or nucleic acid) play some



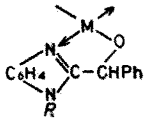
(I)



(II)



(III)



(IV)

part in the activity of the parent compound HBB (I; R=H) and of its 1-alkyl derivatives (I; R=alkyl). Infra-red spectra show that these latter compounds form pairs of intermolecular hydrogen-bonded links as indicated (III), and they also form copper chelates.

Assays were carried out by growing monolayers of *ERK* cells in a number of slowly rotating tubes at 37°. The media were decanted after three days and replaced by fresh media containing half the maximum tolerated concentration of compound and various dilutions of virus (type 1, *L Sc*, 2 *ab*; type 2, *P* 712, *Ch*, 2 *ab*; type 3, *Leon* 12 *ab*). Some controls lacked compound and virus and some lacked compound only. Control tubes containing HBB were also included. Tubes were rolled at 37° and examined twice daily, the time (to the nearest 0·25 day) being noted when half the cells in each tube remained undamaged. The delay in onset of cytopathic change gave an indication of the effectiveness of each compound[1].

The 1,3-dimethyl (II; $R_1 = R_2$ = Me) and the 1-methyl-3-ethyl (II; R_1 = Me, R_2 = Et) quaternary iodides gave no protection and the 1,3-diethyl compound gave just detectable protection against the type 1 and type 3 viruses. However, increase in chain-length produced an improvement; the 1-methyl-3-propyl (II; R_1 = Me, R_2 = ^{n}Pr) and the 1-ethyl-3-propyl (II; R_1 = Et, R_2 = ^{n}Pr) compounds both exhibited a slight, but distinct, effect similar to that shown by 100 μM HBB[1].

The compounds were found to endow cells with marked protection against the type 2 virus. The results, summarized in Fig. 1, show that each quaternary iodide, at half the maximum tolerated concentration (Table 1), had about the same effect as 50 μM HBB. However, in our experiments, as the maximum concentration of HBB tolerated by the cells was 200 μM it is seen that the quaternary iodides had a much lower selective effect than either HBB or its more potent 1-alkyl derivatives[1].

No cytopathic effects were produced in growing cells by the presence of 100 μM potassium iodide and this concentration provided just detectable protection to cells infected with type 2 poliovirus. As the simplest quaternary salts provided no protection against types 1 and 3 viruses, the iodide ion itself gave no protection against these. 1-Methyl-2-(α-hydroxybenzyl)-benzimidazolium iodide (II; R_1 = H, R_2 = Me) had both the same toxicity and offered the same protection as 1-methyl-2-(α-hydroxybenzyl)-benzimidazole (I; R = Me). Although the hydroiodide was probably converted into the 1-methyl derivative of HBB and sodium iodide in the nutrient medium, these results confirmed that the iodide ion was not responsible for the effects produced by the quaternary salts.

Table 1. 1,3-Dialkyl-2-(α-hydroxybenzyl)-benzimidazolium Iododes (II)

R_1	R_2	Maximum tolerated concentration (μM)	M.p. (° C)	Yield (%)	H-bonded OH stretching frequency (cm^{-1})

Et	^{n}Pr	$C_{19}H_{23}IN_2O$	54·2	5·5	30·1	6·6	54·3	5·5	29·8	6·6

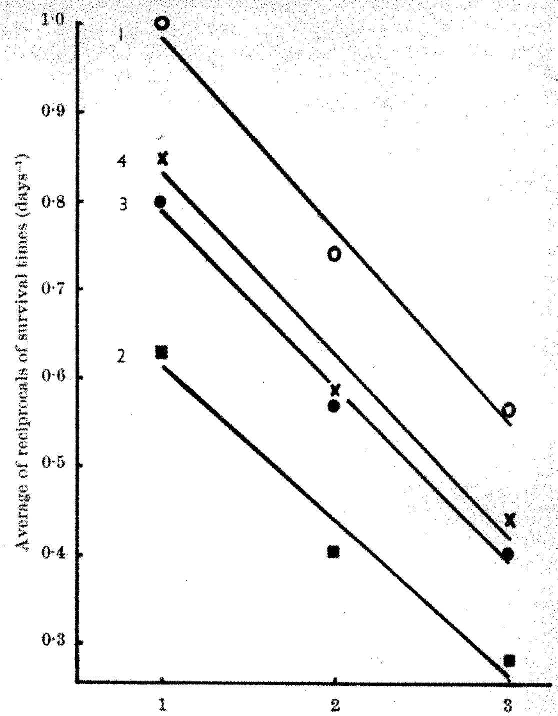

Fig. 1. Lines obtained in assay of protection given to cells against cytopathic effects of poliovirus type 2. (1) Control line (test compounds absent) (○); (2) HBB (100 μM) (strong protection) (■); (3) HBB (50 μM) and 1-methyl-3-ethyl- (50 μM), 1,3-diethyl- (70 μM), 1-methyl-3-propyl- (70 μM) and 1-ethyl-3-propyl- (80 μM) quaternary iodides (●) (same data for all these compounds); (4) 1,3-dimethyl quaternary iodide (40 μM) (×)

The general effect of quaternization is to reduce markedly the protective action of the 1-alkyl derivatives. However, notable protection remains, except with the simpler compounds, against the types 1 and 3 viruses. The OH stretching frequency near 3,200 cm^{-1} in potassium chloride disks and in chloroform (1·5 per cent) (Table 1) shows that quaternization does not reduce the ability of the α-hydroxyl groups to form intermolecular hydrogen bonds, and thus hydrogen-bonded association with other suitable molecules is still possible.

Benzimidazolium salts (II; R_1 = Me, R_2 = Me, Et, ^{n}Pr) were obtained by heating, in a sealed tube at 100° for 24 h, a solution of the 1-methyl derivative of HBB (I; R = Me) (0·002 mole) and the alkyl iodide (0·003 mole) in methanol (1 ml.). The crystalline product, obtained after adding ether, was collected and washed with ether. The 1,3-dimethylbenzimidazolium iodide (II; $R_1 = R_2$ = Me) formed white needles on crystallizing from methanol–ether, while all other benzimidazolium salts, here described, formed white prisms from ethanol–ether after treatment with charcoal.

The 1-ethyl-3-propyl derivative (II; R_1 = Et, R_2 = ^{n}Pr) was prepared in a similar way from the 1-ethyl derivative of HBB, the methanol being replaced by ethanol (1 ml.).

The 1,3-diethyl compound (II; $R_1 = R_2$ = Et) was obtained from the 1-ethyl derivative of HBB and ethyl iodide, nitromethane (1 ml.) replacing the alcohol in the reaction mixture. Otherwise the procedure was unchanged.

1-Methyl-2-(α-hydroxybenzyl)-benzimidazolium iodide (II; R_1 = H, R_2 = Me) was obtained as white prisms, m.p.

194°, by adding ethanol, saturated with hydrogen iodide, to the base (I; R=Me) in ethanol, precipitating the salt with ether and then crystallizing from ethanol–ether.

We thank the National Fund for Research into Poliomyelitis and other Crippling Diseases for generous financial support and Miss Danica Pantic for help with the tissue-culture assays.

Isolation of an Easily Precipitable α_1-Glycoprotein of Human Serum

IN the course of investigations concerning the purification of human serum haptoglobin[1] we found in the α_1-globulin fraction obtained by preparative zone electrophoresis at pH 8·6 a glycoprotein hitherto not described. Because of its unusual ability to precipitate at relatively low concentrations of neutral salts and ethanol we propose to characterize this α_1-glycoprotein by the term 'easily precipitable'.

Preparation was made according to the method illustrated in the scheme of Fig. 1. In the analytical ultracentrifuge (Spinco model E) the glycoprotein exhibited a sedimentation constant of $S^{1\cdot5\%}_{20,w} = 3\cdot8$. The mobility in paper electrophoresis at pH 8·6 corresponds to that of an α_1-globulin. We determined its position in the immuno-electrophoresis diagram of the normal serum with a horse anti-human serum following the technique proposed by Heremans[2] and described by Osserman[3]. As can be seen in Fig. 2, its precipitation line is situated within the α_1-antitrypsin bow. The demonstration of special immuno precipitate is made possible by the addition of α_1-glycoprotein to the normal serum in the concentration of 0·2 per cent (Fig. 2). In the starch-gel electrophoresis the α_1-glycoprotein moves into the position directly behind the albumin as a 'post albumin'[4]. After treatment with neuraminidase isolated from *Vibrio cholerae* the α_1-glycoprotein migrates at a reduced mobility. In starch-gel electrophoresis, it appears to be split into several components.

Some chemical characteristics and the precipitation behaviour of the α_1-glycoprotein 'easily precipitable' are shown in Table 1. For comparison the precipitation behaviour of two other α_1-glycoproteins, namely, the α_1-antitrypsin and the α_1-acid glycoprotein, are also presented in Table 1.

Table 1. CHARACTERISTICS OF THE α_1-GLYCOPROTEIN 'EASILY PRECIPITABLE'

		Precipitation

PHYSIOLOGY

Production of Cardiac Arrest in Animals

THE basic requirement in the study of cardiac resuscitation methods is to obtain a method whereby we can arrest cardiac function in standard circumstances for a predetermined period of time. Numerous methods of inducing cardiac arrest are so far known[1-6].

With the methods of inducing cardiac arrest, the myocardium and its impulse-conducting system is mostly exposed to chemical or electrical trauma. These factors render difficult the evaluation of the methods used for cardiac resuscitation.

In the course of our experiments, we have worked out a new method of cardiac arrest concerning resuscitation, its essence being an artificial tamponade of the pericardium, the arrest of circulation, that is, the creation of clinical death. Our method was as follows: we narcotized animals with chloralose (1 g/kg body-wt.) and incubated them to secure breathing. An open method of recording blood pressure and control continuously with encephalograph (ECG) was applied. We approach the heart through a thoracotomy on the left side. Then with a short, dull-pointed needle connected with the syringe by a rubber tube, we punctured the pericardial sac fixed by tweezers and administered a solution of 150–250 ml. of isotonic sodium chlorate at a medium speed. Caution is needed in puncturing the pericardial sac, and the needle is led parallel to the axis of the heart, thus avoiding damaging any branch of the coronary artery or of the muscles of the moving heart. The needle is fixed carefully so as not to let it slip out during heart-beat. If possible, a fresh puncture is avoided, because the administered solution may flow out through the first hole during over-pressure, which may lessen intrapericardiac pressure and heart function may again spontaneously return at a decreased pressure. The pericardial sac is continuously filled up until it tightens considerably and blood pressure drops to zero.

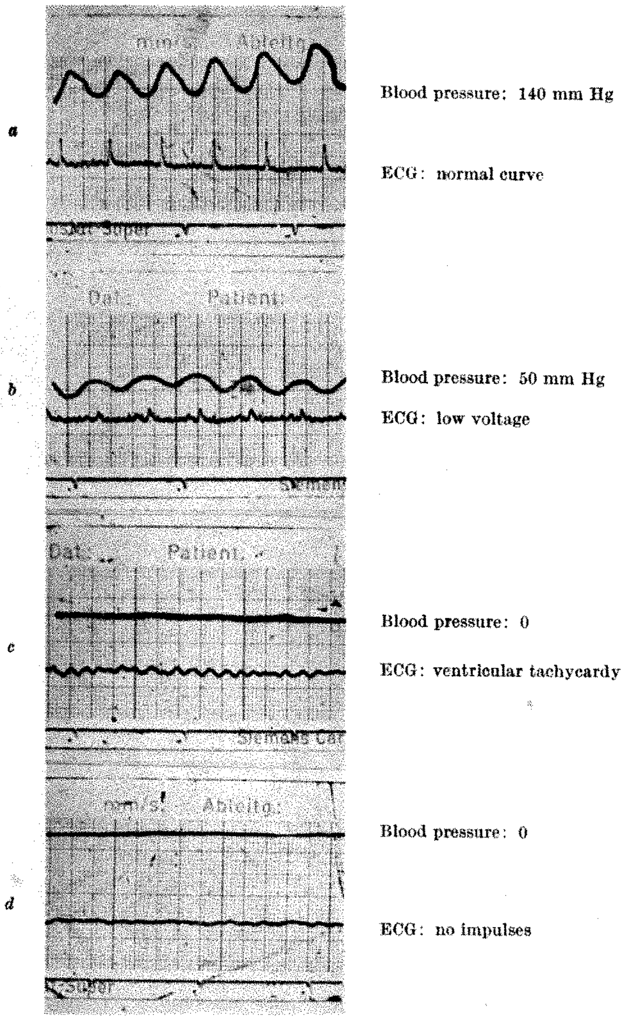

Fig. 1. *a*, Pulse curve and ECG curve of a dog under anæsthesia; *b*, during filling up the pericardial sac; *c*, after complete filling. No circulation ('weak heart'); *d*, 2 min after complete filling up

With this method we have brought about a complete cardiac arrest; at the same time electrical pathological heart action still could be traced by the ECG in a large number of cases. To demonstrate this, the pulse curve was recorded on the ECG tape with the help of a registering set applied on Marey's drum.

This method was carried out on 25 dogs. To determine the beginning of cardiac standstill—after having filled the pericardial sac—we took the tensionless state of clinical death as a beginning and measured time from this point onwards. With the first group of animals (10 dogs) we induced cardiac arrest, lasting for 2–4 min. We gave no drugs, no blood transfusion or infusion during the cardiac arrest and resuscitation. Having stopped the pericardial tamponade, cardiac function returned spontaneously in three cases and it started easily in seven cases after bimanual massage.

In the second group of animals (15 dogs), we induced cardiac arrests lasting for 5–10 min. We included the time needed for splitting the pericardium (30–40 sec), that is, the cessation of the tamponade, into the full time of cardiac arrest.

In this group of animals, resuscitation could only be achieved by bimanual massage if we combined it with intra-arterial transfusion of blood under pressure and with the administration of intravenous noradrenaline. In this group after ceasing pericardial compression we saw fibrillation in five hearts, of which, after successfully defibrillating, we could resuscitate by massage in three cases. In two cases, fibrillation could not be influenced, that is, we failed to achieve resuscitation.

Influence of Duration of Experiment on Rate of Uptake of Radioactive Potassium in Smooth Muscle

THE rates of uptake and loss of radioactive tracers by excitable tissues can often be described by a function involving one exponential term[1-3], but over relatively long periods deviations have been observed from such a simple course[4-7]. The rates of exchange towards the end of such periods are commonly slower than would be predicted from the initial rates and two general causes for this behaviour have been suggested: either the rates are, in fact, diminishing during the course of an experiment or the tissue is not behaving uniformly. This latter possibility has been extensively investigated[1,8-15], because biological material shows an obvious lack of uniformity, and because deviations from single exponential behaviour are observed even when the stoichiometric composition of the tissue remains constant. However, a constant composition is not proof of constant exchange rates but might be maintained if all exchanges in the system slowed down, corresponding perhaps to the slow deterioration of the *in vitro* preparation, or indeed if movement stopped altogether. One might expect deviations due to the ageing of the tissue to be more marked the longer the duration of an experiment, and the uptake of potassium-42 by the smooth muscle of the guinea pig tænia coli has now been examined for such an effect since it only shows serious deviations from single exponential behaviour after 5 h[12].

Unselected guinea pigs were stunned and bled out at the neck, and pieces of tænia coli weighing 6–12 mg were rapidly dissected and suspended with a tension of 2 g in an organ bath containing a modified Krebs solution[14] (Na^+ 137, K^+ 5·9, Ca^{++} 2·5, Mg^{++} 1, Cl^- 144, HCO_3^- 5·9 D(+)-glucose 11·5 mM equilibrated with 99 per cent oxygen/1 per cent carbon dioxide). At appropriate times, muscles were prepared for analysis by wiping them across a 'Perspex' sheet to remove adhering liquid[12], the cotton threads then being cut away and the tæniæ weighed and ashed in hard glass tubes with 0·1 ml nitric acid (sp. gr. 1·5) and 0·1 ml perchloric acid (sp. gr. 1·7) (analytical grades). Samples of the physiological solution and empty control tubes were also prepared. Potassium-42 was measured in the well-crystal of an Ecko scintillation counter *N*664*A*. The total potassium was determined later by flame photometry. All experiments were carried out at 35° C, and were repeated at least six times.

In preliminary observations, pieces of tænia were first loaded with potassium-42 and each was then transferred at 2-min intervals through a series of 20 small organ baths containing inactive Krebs solution. The activity in each organ bath was determined and two semi-logarithmic curves for the efflux were constructed[15], one from the amounts of activity left by the muscle in each organ bath and the other from the total activity in the tissue at each of the same times. This total activity was calculated by adding the residual activity in the muscle at the end of the experiment to the sum of the counts in each of the washing solutions. The rate constants calculated by these two methods should be identical for a tissue showing a single exponential exchange[15], but in the present experiments they differed by more than 50 per cent.

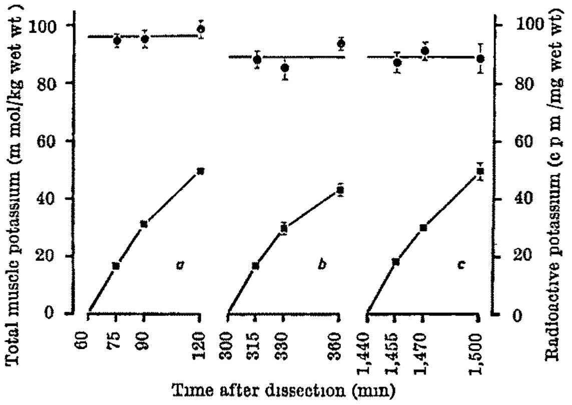

Fig 2. Total potassium (circles) and uptake of potassium-42 (squares) by the tænia coli. Muscles were transferred to radioactive solutions at different times after dissection, but no progressive change in the initial rate of uptake of potassium-42 was observed. The specific activity of solution was 10^5 c.p.m./m mole potassium

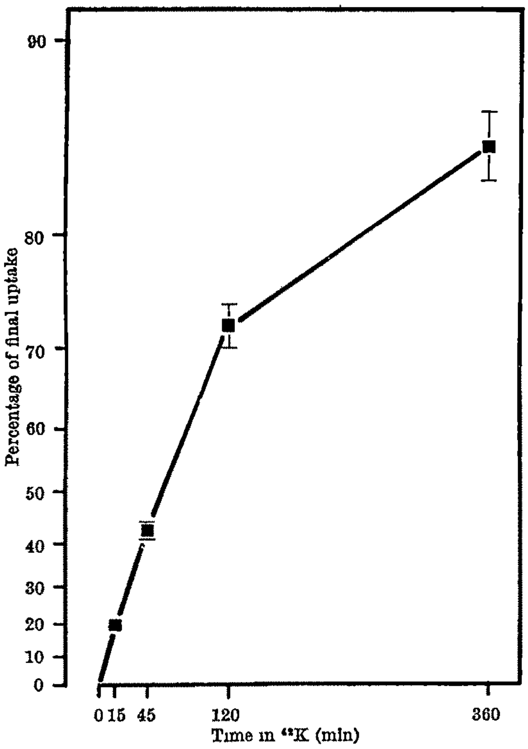

Fig 1. Uptake of potassium-42 by the tænia coli. The logarithmic ordinate scale corresponds at infinity to the uptake observed after 1,440 min. The time-scale is linear. The points show typical deviations from a straight line, even though all muscles were kept the same period *in vitro*. The *S.E.* of each mean has been individually calculated and shown where it was big enough

In further experiments a potassium-42 uptake curve was constructed for pieces of tænia which had all been kept in Krebs solution *in vitro* for 25 h before analysis. Five muscles from each guinea pig were suspended in inactive solution after dissection, and the first of these was transferred to radioactive solution 1 h later when the net potassium content had reached a steady state[12]. The remaining muscles were transferred at intervals thereafter until, 1,475 min after dissection, all were in the active organ bath together. A sixth muscle from the same animal had been placed in the radioactive bath immediately after dissection, at which time there was a restoration of the net potassium which had initially been lost from the tissue during the cold preparation period[12]. This net gain contributed to the radioactive content of the last muscle by giving it an extra opportunity to take up tracer, and it was removed with the others and prepared for analysis after 1,500 min.

If there were no ageing effects, these observations should give similar results to those found by Goodford and Hermansen: single exponential uptake over the first 120 min, followed by a progressive slowing during the next 3 h. If, on the other hand, there were a marked deterioration of the tissue *in vitro*, the shorter uptake periods (which only began towards the end of the experiments when the muscles were already ageing) should be most affected and deviations in the reverse direction might even occur. The results in fact resembled Goodford and Hermansen's[12], but suggested that exchange was virtually complete after 1,440 min, first, because the relative activity ($S.A._{\text{muscle}}/S.A._{\text{solution}}$) of 1·006 did not differ significantly ($0·9 > P > 0·8$) from 1, and secondly, because the muscle which went straightway into the active organ bath, and therefore had additional opportunities and time (1,500 min) to take up more potassium-42, in fact took up no more.

In Fig. 1 the radioactive uptake after the shorter periods in radioactive solution has been plotted with a logarithmic ordinate, adjusted so that the observed uptake after 1,440 min would be at infinity on this scale. With the axes of Fig. 1, the points should have been on a straight line if uptake followed a single exponential course, although the method of least squares was not applicable to the calculation of the best linear regression to fit the points, because after the logarithmic transformation the later observations were relatively more scattered than the earlier results This has been shown in Fig 1, where the standard error of the mean has been separately drawn for each time of observation. It may be seen clearly by inspection that no straight line could pass close to all the points, a single exponential course could describe the observations at 15, 45 and 120 min adequately, but deviations arose after 300 min just as they did in the conventional experiments of Goodford and Hermansen[12] These deviations from a single exponential were not due to variation between guinea pigs since the effect was observed in each individual animal, nor were they artefacts due to the assumption that exchange was complete after 1,440 min This was, of course, implied in the selection of the logarithmic ordinate scale, but the relative activity could not exceed 1 at equilibrium and any smaller value would only accentuate the curvature in Fig 1

It may be concluded from the previous considerations that the potassium in the tænia coli was not uniformly distributed However, the effect of duration of experiment on rate of exchange was investigated in a further series of experiments in which nine muscles were dissected from each guinea pig and placed in inactive Krebs solution Three were transferred to the radioactive organ bath after 60 min and were removed for analysis during the next hour (Fig 2*a*) Three more pieces were transferred after 300 min and similarly observed (Fig 2*b*), while the remaining three muscles were only transferred to radioactive solution after 1,440 min (Fig 2*c*) The results in Figs 2*a*, *b* and *c* are similar, and in particular do not show any progressive change in the initial rate of uptake of potassium-42 after *in vitro* pre-incubation periods as long as 24 h The later, slower exchange of potassium in the tænia coli[12] is therefore largely, or entirely, due to a lack of uniformity in the tissue, as is commonly assumed, and is not appreciably due to any deterioration of the preparation *in vitro*

Effect of Calcium Ions on Melanophore Dispersal

It has been suggested that calcium ions act as the coupling agent in muscle excitation and contraction[1,2], in stimulation of the adrenal medulla and cortex[3], and in vasopressin release from the posterior pituitary[4] Their basic role in membrane reactions has become obvious from many other observations, including that on which we wish to report here

Hydrated Na^+ and Ca^{++} ions are of similar size[5], so that cross-action and synergism in biological phenomena may be expected This applies also to nervous conduction, where calcium behaves similarly to sodium it enters during excitation and leaves during recovery[6], probably playing a key part in this process[7] In view of this interrelation, it seemed unlikely that the melanophore dispersing action of melanocyte stimulating hormone should be specific to sodium[8–10]

In a series of 200 examinations the skin from the back of tree frogs (*Hyla arborea*) was removed, halved longitudinally and flattened on filter paper with its green-coloured side facing upwards The skin was then incubated at room temperature for an hour in frog-isotonic sucrose solution, buffered with 2 mM sodium bicarbonate This procedure was shown to bring extracellular ions down to inert concentrations without significantly affecting the tissue-bound calcium[9] After incubation, half the skin was soaked in different mixtures of frog-isotonic sucrose and isotonic cation chloride solutions, both buffered with 2 mM sodium bicarbonate, the other half was kept in buffered sucrose solution for control, the Na^+ of the buffer being ineffective at this concentration (2 mM)

Osmotic activity was checked by the Fiske osmometer The colour of the skin was recorded every 15 min for 3 h according to the colour scale introduced by us[11] With this method we found that 10 mM calcium chloride not only supported melanocyte stimulating hormone action, *in vitro*, but also caused considerable darkening by itself Higher concentrations caused lightening (yellowish colour) or inhibition of action of melanocyte stimulating hormone Among other bivalent ions, only Mg^{++} behaved like Ca^{++} in supporting action of melanocyte stimulating hormone, but none of them, in concentrations up to isotonicity, led to darkening of the skin.

After soaking the skin in frog-isotonic K^+ solution, the melanophore dispersal could still be induced by 10 mM Ca^{++}, this cation acting as a darkening agent by itself, or in support of action of melanocyte stimulating hormone Melanophore response to Ca^{++} after depolarization by K^+ solution may thus be comparable with smooth muscle response under similar conditions[2]

We accordingly propose as a working hypothesis that Ca^{++} may be the coupling agent between melanocyte stimulating hormone stimulation and melanophore dispersal, having a coupling function parallel to that postulated for muscle[1] and other systems[3,4].

In conclusion we have found that Ca^{++} alone in proper concentrations causes *in vitro* darkening of the skin of the tree frog (*Hyla arborea*)—even in frog-isotonic potassium chloride Melanocyte stimulating hormone may be presumed to act primarily on the cell membrane, its melanophoric effect being mediated by Ca^{++} The melanophore reaction may therefore serve as an easily accessible model reaction for examining coupling phenomena.

PHARMACOLOGY

Enhancement by Methyldopa of Tyramine Sensitivity in Man

THE mechanism by which α-methyl-3,4-dihydroxy-L-phenylalanine (methyldopa, Aldomet) lowers blood pressure in man has not been established definitely While the inhibiting activity of the drug on decarboxylation of aromatic-L-amino-acids has been confirmed in human subjects and indeed was our reason for first studying the compound clinically[1], it is doubtful that synthesis of the sympathetic transmitter, noradrenaline, is significantly affected by the drug Thus, investigations in this laboratory and elsewhere[2] have failed to show any decrease in the urinary excretion of the catecholamine metabolite, vanilmandelic acid, in patients receiving the drug Furthermore, depletion of tissue-levels of noradrenaline by methyldopa and α-methyl-*m*-tyrosine in animals appears unrelated to the enzyme-inhibiting effects of these compounds[3] Present evidence[4,5] favours mediation of the depleting effect by amine metabolites formed by decarboxylation (to α-methyl-dopamine) and possibly subsequent β-hydroxylation (to α-methyl-noradrenaline)

While the blood pressure effects of methyldopa in man resemble in part those of sympathetic neuronal inhibition, it is not known whether catecholamine depletion occurs in human subjects An index of this might be obtained by following changes in pressor activity of tyramine since the cardiovascular effects of tyramine are thought to be mediated by noradrenaline and are depressed by catecholamine-depleting agents such as reserpine[6] Accordingly, responses to separate 15-min infusions of tyramine at several dose-levels were determined in five hypertensive patients under three different conditions · (1) during control periods , (2) after 4–20 weeks of oral treatment with 2–3 g of methyldopa daily , (3) during the last three days of treatment with reserpine 1–2 mg/day intramuscularly for eight days Control observations were made at a time when the patients had received no medical treatment for at least 4 weeks

The rate of infusion of tyramine in μg/min required to produce an increase of 30 mm mercury in the systolic blood pressure was calculated from dose response curves Responsiveness to tyramine was expressed as a percentage of the average control values As shown in Table 1, the anticipated decrease in tyramine sensitivity occurred in association with presumed noradrenaline depletion produced by reserpine While a decrease in tyramine pressor activity was also expected during treatment with methyldopa, it may be seen that pressor responses to tyramine were actually enhanced by this agent

Table 1. EFFECT OF RESERPINE AND METHYLDOPA ON RELATIVE SENSITIVITY TO TYRAMINE IN FIVE PATIENTS*

Case No	After reserpine† (1–2 mg/day) (%)	After methyldopa‡ (2–3 gm/day) (%)
1	25	215
2	30	125
3	33	183
4	34	145
5	16	194
6	—	220

* Responsiveness is expressed as percentage of control sensitivity

† Each value is the average of two determinations carried out after 6–8 days of intramuscular reserpine, 1–2 mg/day

‡ Each value is the average of 2–6 determinations done after 2–14 weeks of administration of methyldopa (2–3 g/day) All values were above the average control-level (100 per cent)

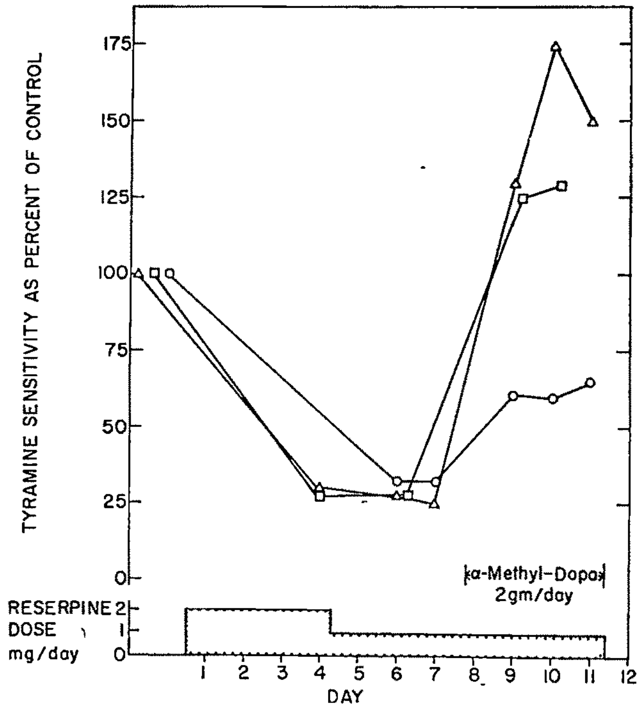

Fig 1 Depression of tyramine pressor responses in three patients by reserpine and restoration by methyldopa

It was of interest to learn whether the depressed tyramine sensitivity due to reserpine could be reversed by methyldopa Three additional hypertensive patients were given 1–2 mg reserpine intramuscularly daily for 11 days ; during the last three days methyldopa 2 0 g/day was given orally Tyramine sensitivity was increased in each of the three patients and in two of them even beyond pre-reserpine control-levels (Fig 1) The restoration of tyramine sensitivity by methyldopa was substantiated further in numerous studies in reserpinized dogs and rabbits[7] α-Methyl-dopamine and α-methyl-noradrenaline were found also to restore tyramine pressor activity Peak restoration was delayed for about 90 min following the amino-acid drug and its decarboxylation product, but was immediate following administration of α-methyl-noradrenaline. Recently, similar work on animals has been reported from two other laboratories While not presenting data, Day and Rand[8] state that they have observed partial restoration of responses to sympathetic nerve stimulation and to tyramine in reserpine-treated animals after infusions of methyldopa and the two amine derivatives Varma and Benfey[9] report that in spinal cats pretreatment with methyldopa prevented the reserpine-induced reduction of cardiovascular responses to tyramine but not to stellate-ganglion stimulation

These findings are interpreted as affording presumptive evidence that the enhanced tyramine response produced by methyldopa is mediated by its amine metabolites, α-methyl-dopamine and/or α-methyl-noradrenaline Both these compounds are pressor substances In human subjects we have found that the pressor potency of α-methyl-dopamine is about 1/100 that of noradrenaline As reported previously[10], α-methyl-noradrenaline is about 1/3 as potent as noradrenaline in increasing the systolic blood pressure in man This information on pressor potency plus the timing of the restoration of tyramine responses in reserpinized animals[7] tends to favour the β-hydroxylated amine as being the mediator in enhancing and restoring tyramine responses The supersensitivity to tyramine of patients treated with methyldopa may be related to the fact that the α-methyl-amines are not substrates for monoamine oxidase This could facilitate their access to receptors following release from a tyramine-sensitive site at the nerve ending

A better understanding of the mechanism of hypotensive action of methyldopa may result from a more detailed investigation of tyramine responses, as well as studies of the interactions of noradrenaline and the α-methyl-amines at receptor sites in the arterioles and in the brain During preliminary investigations we have found that the clinical hypotensive response, in both degree and duration, bears a closer relationship to the magnitude of tyramine response than to any other parameter While this evidence is indicative of a peripheral site of drug action, it must be borne in mind that methyldopa also has central activity Furthermore, frequent lowering of blood pressure in man in the supine as well as erect positions is difficult to explain solely on the basis of a peripheral action on sympathetic mechanisms

Acetylcholine-releasing Material in Neural Tissues

WHILE examining cholinergic substances in sciatic nerve[1], we noted that acetone extracts of nerve caused a slow contraction of the guinea pig ileum (Fig 1*A*) Identical lipid extracts of brain had the same effect (Fig 1*B*) ; similar activity could not be detected in kidney, intestine, lung or liver A salient characteristic of the lipoidal material is that its action is completely blocked by atropine at a dose, 6 ng/ml , that blocked the action of acetylcholine The lipoidal material causes a slower contraction than does acetylcholine (Fig 1) , the material is resistant to acetylcholinesterase, which destroys acetylcholine ; the material retains activity after heating at *p*H 10 for 5 min in a boiling water bath, conditions which destroy acetylcholine, the material does not act on a strip of ileum that had been stored either at room temperature for 1 day or at 4° C for 3 days, whereas acetylcholine elicits the usual contractions , finally, the material is not active on the anoxic ileum, which responds to acetylcholine (Table 1)

Failure of the material to act on the stored[2] or anoxic[3] ileum (Table 1), and the sensitivity of the activity to atropine suggested that the substance may act by releasing acetylcholine from the nerve plexus in the wall of the ileum This inference was strengthened by investigations with a hemicholinium (HC-3), which prevents the synthesis of acetylcholine in nervous tissue[4,5] and prevents the action of the extract on the ileum without inhibiting the effect of either acetylcholine or bradykinin (Fig 2)

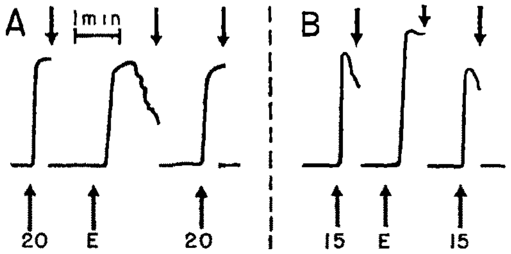

Fig 1. *A*, Action of a lipid extract (*E*) of the sciatic nerve of the rabbit on the guinea pig ileum , *B*, Action of a lipid extract of pig brain on the guinea pig ileum Numbers refer to ng of acetylcholine The ileum was bathed in 5 ml of Tyrode's solution containing mepyramine, 5 μg/l , and lysergic acid diethylamide, 50 μg/l

Table 1 EFFECT OF VARIOUS CONDITIONS AND DRUGS ON THE ACTION OF THE EXTRACT ON GUINEA PIG ILEUM

Treatment	Concentration (μg/ml)	Activity of extract (% of normal)
Storage of ileum		
24 h, 26° C	—	0
3 days, 4° C	—	0
Anoxic ileum	—	0
Incubation with acetylcholinesterase	—	100
Heating extract at *p*H 10 for 5 min	—	290
Lysergic acid diethylamide	0 500	100
Mepyramine	0 005	100
Atropine	0 006	0
HC-3	(2 × 10^{-5} M)	13
Hexamethonium	20 0	100
Tetraethylammonium	40 0	106
Cocaine	4 0	101
Morphine	0 001	0

The action of the material cannot be accounted for by a stimulation of the ganglia in the wall of the ileum, for hexamethonium and tetraethylammonium, in doses that block the action of ganglionic stimulants[6], did not inhibit the action of the extract Since cocaine did not prevent its action, the material cannot be acting through stimulation of the nerve fibres in the ileum[7]. Blockade by morphine (Table 1) in doses that prevent the release of acetylcholine from nerve endings[8,9] strongly implies that the material causes contraction by releasing acetylcholine from the nerve endings in the ileum Direct evidence that the extract causes enhanced release of acetylcholine was obtained by measuring[9] the amount of acetylcholine released in 20 minutes from the resting ileum, before and after exposure to the nerve extract (Fig. 3)

The material differs from substance *P*, the effect of which was not blocked by atropine It also differs from bradykinin not only in its inhibition by HC-3 (Fig 3), but also in its antagonism by atropine The action of 5-hydroxytryptamine is inhibited by lysergic acid diethylamide and cocaine, while the effect of histamine is inhibited by mepyramine , none of these inhibitors influenced the action of the extract (Table 1)

The material may function in a presynaptic event leading to release of the neurotransmitter at cholinergic nerve endings[10-12] and, therefore, may be implicated in the action of botulinum toxin, which prevents release of the cholinergic transmitter, and in myasthenia gravis, in which a presynaptic malfunction has been suggested Perhaps of greater interest is the observation that morphine totally blocks the action of the material on the ileum ; the ileum, in responding to analgesic drugs in a manner that reflects analgesic potency and in developing 'tolerance' to and 'dependency' on morphine, demonstrates a neural network that is analogous to more complicated networks[9]

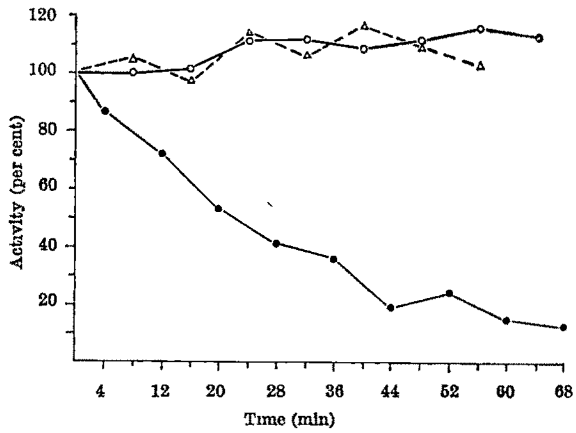

Fig 2 The inhibition by HC-3 of the action of the extract from sciatic nerve Tyrode's solution containing 2 × 10^{-5} M of HC-3 was added to the chamber containing the guinea pig ileum at zero-time At intervals of 4 min, the test substances were added to the bath In one experiment, 200 ng of bradykinin (○) was compared with the extract (●) , in another, 20 ng of acetylcholine (△) The curve showing activity of the extract is the average of both experiments

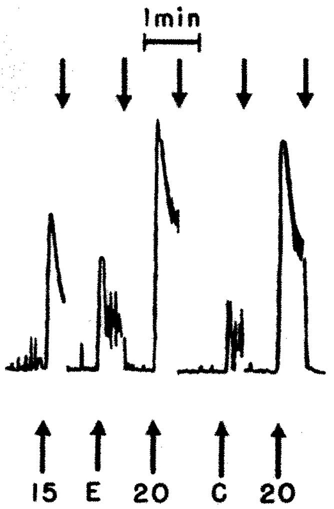

Fig. 3. Enhanced release of acetylcholine from the ileum by the extract of sciatic nerve. Numbers refer to ng of acetylcholine. *E* 1·0 ml. of Krebs–Henseleit solution from the 5·0 ml. in which the ileum (0·35 g) had been immersed with the extract for 20 min. *C* identical with *E*, except that no extract was added to the chamber. In the absence of the extract, 62·2 ng of acetylcholine was released from the ileum in 20 min; in the presence of extract, 87·3 ng was released.

HÆMATOLOGY

Induction of Viscous Metamorphosis in Human Blood Platelets by means other than by Thrombin

Viscous metamorphosis is characterized by the morphological and biochemical changes displayed by the blood platelets during the coagulation of blood. Thrombin is generally thought to be the activating agent. In the course of viscous metamorphosis, vasoactive substances including 5-hydroxytryptamine, adrenaline and histamine, as well as phospholipids (platelet factor 3) essential for intrinsic prothrombin conversion are liberated. Viscous metamorphosis, furthermore, is of major importance for the formation of an efficient hæmostatic plug as well as of the primary white thrombus. In view of all these facts it seemed worth while to investigate whether agents other than thrombin were capable of inducing viscous metamorphosis in normal human blood platelets.

The agglutination of platelets as well as the liberation of vaso-active amines or phospholipid by the action of antigen–antibody complexes[1–5], of endotoxin[6,7], and of anaphylatoxin[2] has been reported. Complement participation has been considered essential at least in some of these reactions. Since complement also depends for its activation on the presence of metal ions, a participation of the blood clotting system cannot be excluded in several of the experiments reported, particularly since the 'plasmatic atmosphere', even of washed platelets, contains most of the factors required for thrombin formation.

Recently it has been reported that a heparinoid (polyanetholsulphonate–'Liquoid', Roche) is also capable of inducing *in vivo* morphological platelet changes resembling viscous metamorphosis[8]. Heparinoids, like heparin, generally display antithrombin and anticomplement activities. In the experiments reported here, the effects of 'Liquoid' and of antigen–antibody complexes on platelets have been studied under conditions which exclude participation of the blood clotting system.

Washed human blood platelets were isolated as described before[9] and used within 24 h after collection. Adenosine triphosphate was determined in samples deproteinized with 3 per cent trichloroacetic acid; commercial reagents were used (Boehringer und Söhne, Mannheim, Germany). 'Liquoid' (Roche) was brought to a 1 per cent solution in 0·15 M saline. Insoluble antigen–antibody complexes were prepared by incubating the antigens (human serum albumin obtained from the Central Laboratory of the Blood Transfusion Service of the Swiss Red Cross, Berne, or chicken serum) with the corresponding rabbit antisera for 30 min at 37° C. The serological precipitates formed were collected by centrifugation and resuspended in an undiluted commercial hirudin solution. ('Hirudex', ANA, Paris.) Hirudin acts as a powerful inhibitor of thrombin.

All incubation mixtures contained the following components: 20×10^6 platelets/µl.; imidazole–hydrochloric acid buffer, *p*H 7·4, 0·03 M; EDTA 0·005 M; $MgSO_4$ 0·008 M; highly purified human fibrinogen 0·05 per cent; and sufficient sodium chloride to bring the mixture to isotonicity (300 µmoles/ml.). To this were added: thrombin (3·8 I.U./ml.), or 'Liquoid' (Roche) (0·05 per cent), or antigen–antibody precipitate (0·3 per cent protein). Values in parentheses represent final concentrations in total incubation mixture.

The addition of 'Liquoid' leads to an immediate aggregation of the suspended platelets, followed by active contraction of the formed aggregate. In fact, speed of contraction and general appearance of the contracted aggregates are indistinguishable from those formed by the action of thrombin (Fig. 1). ATP is consumed in the course of the action of 'Liquoid' on platelets, and the resultant curves of ATP-consumption are identical with those obtained after addition of thrombin (Fig. 2).

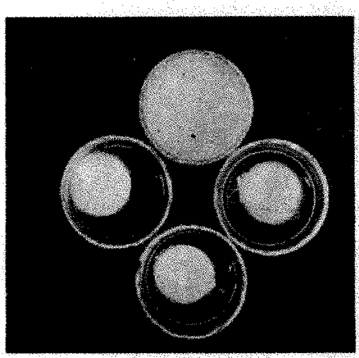

Fig. 1. Top, Non-retracting platelet-rich clot, obtained by the addition of thrombin in the presence of an excess of EDTA; bottom, retracted clot (with thrombin and Mg^{++}-ions); left, retracted platelet aggregate (with 'Liquoid' + Mg^{++}-ions); right, retracted platelet aggregate (with antigen–antibody precipitate + Mg^{++}-ions + hirudin)

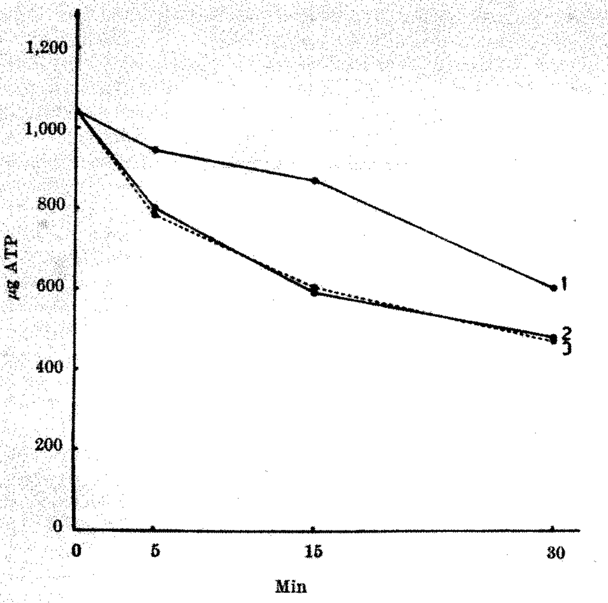

Fig. 2. ATP-levels in platelets incubated with: (1) 0·15 M sodium chloride; (2) 'Liquoid' (Roche); (3) thrombin

Mixtures of human platelets and human albumin–antialbumin precipitates also show contractile activity and ATP consumption, the only difference being that the reaction proceeds at a slower rate. An immune complex formed from chicken serum and rabbit anti-chicken antiserum gave similar results. In Ouchterlony tests, chicken serum proteins did not show evidence of cross-reaction with human serum. This indicates that immune complexes devoid of components which might be present as antigens in the 'plasmatic atmosphere' of the platelets still react in the same way.

These results leave no doubt that typical manifestations of viscous metamorphosis, that is, ATP-consumption and retractile activity, are shown by human platelets under the influence of a heparinoid as well as in the presence of antigen–antibody complexes. In the latter instance, viscous metamorphosis occurred in spite of the presence of hirudin, a powerful inhibitor of thrombin. The release of vasoactive amines and of phospholipid from platelets under a variety of experimental conditions therefore must be considered also as typical manifestations of viscous metamorphosis. A primary activation of the clotting system does not seem necessary. A participation of the complement system, although unlikely, cannot be entirely excluded on the basis of these experiments. Platelets contain a powerful antiheparin factor and a 'plasmatic atmosphere', as well as plasmatic inclusions which could contain complement.

Platelets undergoing viscous metamorphosis, particularly the phospholipids liberated in this process, may act as a trigger for the activation of the intrinsic clotting system[10]. In a variety of experimental conditions, including injections of endotoxins (generalized Shwartzman phenomenon) and 'Liquoid' as well as some reactions elicited by circulating antigen–antibody complexes, the deposition of fibrin in the vascular system dominates the pathogenic picture[8,11]. The evidence presented here suggests that fibrin formation may be a secondary phenomenon resulting from the induction of viscous metamorphosis of the blood platelets by other means than thrombin.

We thank Miss M. Schneider for assistance with these experiments and Prof. H. Fey, Department of Veterinary Bacteriology, University of Berne, for kindly supplying a sample of chicken serum and the corresponding rabbit antiserum.

Effect of Nitrogen Mustard on Erythrocyte Acetylcholinesterase

NITROGEN mustard (HN_2) is known to inactivate certain enzymes, particularly hexokinases and phosphatases[1], in addition to the better-known effects on nucleic acids common to all alkylating agents[1–5]. In the course of examining the effects of nitrogen mustard on circulating erythrocytes, it became important to assay its effect, if any, on erythrocyte acetylcholinesterase. This enzyme is located on the red cell surface, accessible to trypsin inactivation[6].

Determinations were first attempted in the rat, but no erythrocyte acetylcholinesterase activity could be demonstrated in this animal, using Sabine's method[7]. Reports of acetylcholinesterase activity in cellular fractions of rat's blood[8] are undoubtedly due to the presence of platelets, in which it is present in unusually high quantities[9]. *In vitro* determinations of human red cell acetyl-

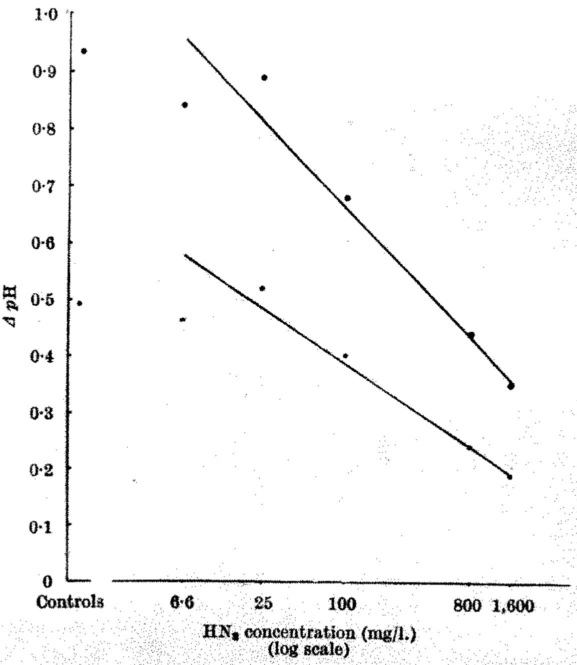

Fig. 1. Observed *p*H change, due to erythrocyte acetylcholinesterase activity, after incubation with 5 concentrations of nitrogen mustard (HN_2) for 1 h at 4° C. Readings were taken after incubation with substrate (acetylcholine) for 30 min (small dots) and 60 min (large dots)

cholinesterase activity were therefore undertaken, using Burman's modification[10] of Michel's method[11]. Twice-washed erythrocytes, resuspended in an equal volume of 0·85 per cent saline, were incubated at 4° C with 5 concentrations of nitrogen mustard:

(*a*) 6·6 mg/l., which, assuming a total blood volume of 60 ml./kg (ref. 12), is equivalent to a therapeutic dose of 0·4 mg/kg; (*b*) 25 mg/l., equivalent to the LD_{50} of 1·5 mg/kg; (*c*) an arbitrary concentration of 100 mg/l.; (*d*) a concentration of 800 mg/l., recommended for chemical sterilization of blood[13]; (*e*) an arbitrary concentration of 1,600 mg/l. Incubation with acetylcholine in buffer at 23° C was commenced 1 h after addition of nitrogen mustard, and *p*H change recorded at 30 and 60 min.

Results are shown in Fig. 1. Activity appears to be unaltered by 1 h exposure to therapeutic or LD_{50} levels of the drug. On the other hand, an effect is apparent in the concentration range from 100 to 1,600 mg/l., and this effect is approximately related to the log of the concentration. These concentrations, however, can only be produced *in vitro*, and it appears that nitrogen mustard has no direct effect on the acetylcholinesterase of circulating erythrocytes at levels likely to be found in biological usage.

HISTOCHEMISTRY

Influence of Adrenocorticotrophic Hormone, Hydrocortisone and Hypophysectomy on the Distribution of β-Glucuronidase in the Adrenal Cortex of the Rat

In an extensive investigation of the activity and localization of several enzymes found in the rat adrenal cortex in different experimental circumstances, striking changes were noticed in the localization and the activity of the enzyme, β-glucuronidase.

Four groups of animals were examined. Each group consisted of 5 males and 5 females weighing 150 g: group I, control animals; group II, animals receiving 2 I.U. ACTH daily for 10 days, subcutaneously; group III, animals receiving 2 mg hydrocortisone daily for 10 days, subcutaneously; group IV, animals killed 10 days after hypophysectomy.

The rats were killed under ether anæsthesia. The adrenals were dissected and stored for several days at −20° C. Sections with a thickness of 10μ were made in a cryostat. The Fishman and Baker[1] method was used to demonstrate the presence of β-glucuronidase.

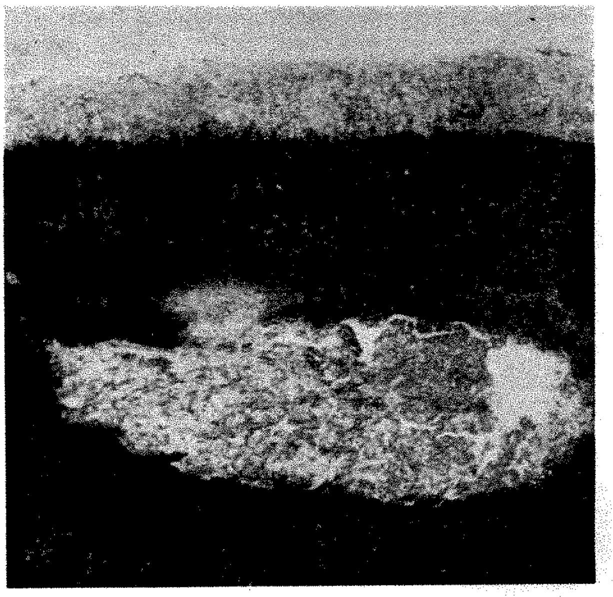

Fig. 1. β-Glucuronidase activity of the adrenal cortex after treatment with hydrocortisone (× 25)

Unlike most enzymes (alkaline phosphatase, acid phosphatase, 5 nucleotidase, adenosine triphosphatase, esterases, aminopeptidase, succinic dehydrogenase and several other dehydrogenases) which are more or less specific for a special zone and correlate with an increase and decrease in the width of these zones, β-glucuronidase showed a completely different localization under the various experimental conditions.

The control animals and the animals treated with ACTH and hydrocortisone showed, apart from changes in the width of the zones, no striking differences. The β-glucuronidase was localized in the zona reticularis and the zona fasciculata (Fig. 1). The peripheral part of the zona fasciculata in particular showed strong activity. No

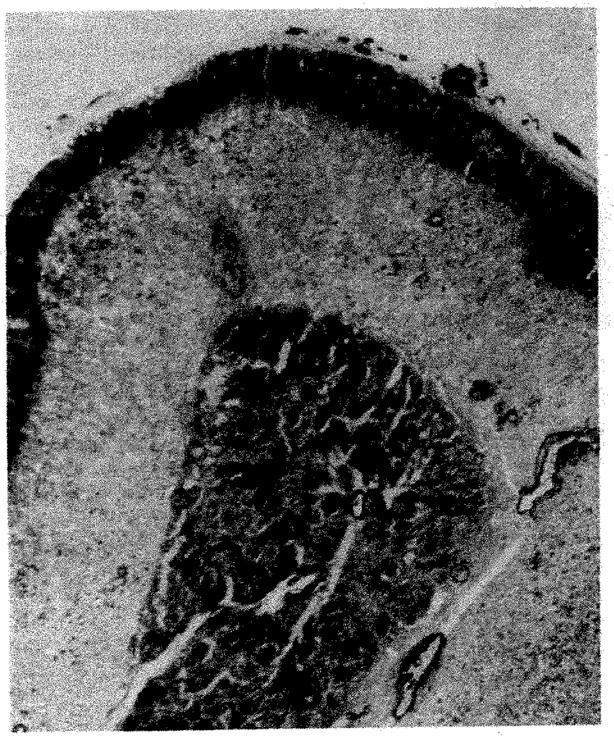

Fig. 2. β-Glucuronidase activity of the adrenal cortex after hypophysectomy × 25)

activity was found in the zona glomerulosa. This enzyme pattern is similar to that found by Fishman and Baker in normal animals. Nayyar and Glick[2], who estimated the enzyme in tissue fragments, also found strong activity in the central part of the cortex, diminishing gradually towards the capsule.

A different pattern was found in the adrenals of hypophysectomized animals. Here the zona glomerulosa and the most peripheral part of the zona fasciculata were strongly positive and the zona reticularis negative (Fig. 2). This observation is in agreement with the quantitative estimations of β-glucuronidase in cortical fragments of hypophysectomized animals made by Nayyar and Glick. These authors found that after hypophysectomy the activity of β-glucuronidase was diminished, the decrease being less than would be expected from the decrease in weight. This slight total decrease can be explained by the increased activity in the zona glomerulosa found in our experiments.

Both hypophysectomy and treatment with cortisone induce atrophy of the adrenal cortex. Our findings suggest that there is a principal difference in functional activity under these two conditions.

Although Janigan and Pearse[3] did not accept Fishman's and Baker's method as specific for β-glucuronidase, the changes found with this method after hypophysectomy suggest such a specificity.

A Histochemical Technique for the Demonstration of Cytochrome c

HITHERTO no method has been reported for the histochemical demonstration of cytochrome *c* in tissue sections. It has recently been shown, however, that cytochrome *c* behaves like a 'true' peroxidase at low *p*H in a pyrogallol-hydrogen peroxide system[1]. In this communication a method is described based on the peroxidatic activity of cytochrome *c*.

The kidneys of adult albino rats (Wistar strain) were used because they are known to be rich in cytochrome *c*[2]. The rats weighed 220–355 g, and were fed a normal diet *ad libitum*. The kidneys were perfused *in situ* through the aorta with a dextran preparation ('Intradex', Nyegaard and Co., Oslo). After perfusion the kidneys appeared quite pale both on the surface and in sections. The freeze-drying technique was used as the *in vivo* localization of proteins is preserved by this procedure[3]. Transversal blocks of about 1 mm in thickness were prepared, mounted on copper plates and rapidly frozen in isopentane cooled by liquid nitrogen[4]. Thereafter, they were dried *in vacuo* at a temperature between −35° C and −40° C. Next, the tissue blocks were infiltrated for 1·5 h *in vacuo* at 40° C by a mixture of polyethylene glycols (Farbwerke Hoechst AG, Germany), grade 1,000 and 600 (2 : 1, v/v (ref. 5)). Finally, they were embedded in a mixture of polyethylene glycols, grade 2,000 and 1,000 (56 : 44, v/v (ref. 6)). Polyethylene glycol was used because the sections could then be placed into the staining solution without further pre-treatment. Serial sections of 5μ were cut, and put into absolute acetone. The sections sank to the bottom, and the polyethylene glycol disintegrated partly, leaving the cytochrome *c* unextracted. The wrinkles flattened out well, and the sections were transferred to cool glass slides, and air-dried. Persisting small amounts of the wax were dissolved in the staining solution. Alternatively the sections were mounted directly on to the slides by gentle pressure by the finger[6]. The sections always adhered to the slides throughout the procedure.

Serial sections were stained by one of the following methods: (1) Ehrlich's hæmatoxylin/eosin; (2) Beneš's staining for mitochondria[7]; (3) peroxidase staining for the demonstration of cytochrome *c* as described in the following text.

Out of a number of oxidizable substances tested, only benzidine, with sodium nitroprusside present, was found satisfactory. The following method was found empirically to give optimal histochemical results:

Reagents:

A	Benzidine	0·3 g
	Sodium nitroprusside	0·2 g
	Ethanol (70 per cent, v/v)	150 ml.
	Glacial acetic acid	1 ml.
	The *p*H of this solution was about 4·8.	
B	Hydrogen peroxide (30 per cent, w/v)	2·5 ml.
	Glacial acetic acid	2·0 ml.
	Ethanol (70 per cent, v/v)	100 ml.
	The *p*H of this solution was about 3·6.	

The sections were left in solution *A* for 1–10 min and then directly transferred to solution *B* for 1 min. After thorough washing in 70 per cent ethanol, they were counterstained for 1 min in 1 per cent aqueous solution of neutral red. The sections were then dehydrated and cleared through the usual ethanol–xylene series and mounted in 'DePeX' mounting medium (George T. Gurr, Ltd., England).

The quality of the freeze-drying was revealed by staining with hæmatoxylin–eosin, and the mitochondria were visualized by the specific staining according to Beneš. Peroxidase activity attributable to cytochrome *c* caused the appearance of dark blue cytoplasmatic granules (Fig. 1). The nuclei and the cytoplasm, except for the mitochondria, stained deeply red, providing an excellent contrast. The granules, representing precipitates of oxidized benzidine ('benzidine blue'), were confined to the mitochondria; actually, these appeared better defined than in sections stained with conventional techniques. The precipitates of 'benzidine blue' are very stable, and the sections could be stored without special precautions for at least a year.

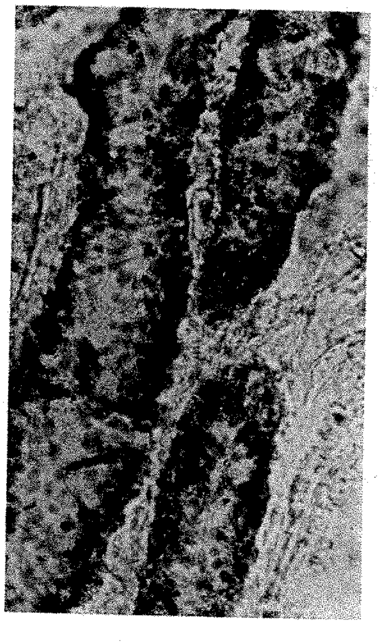

Fig. 1. The intracellular distribution of peroxidase activity, attributable to cytochrome *c*, in the thick, ascending limb of Henle's loop in the outer medullary zone of the rat kidney. Finely coarsed, dark blue precipitates of oxidized benzidine ('benzidine blue') are seen tightly packed basally and perinuclearly, closely confined to the mitochondria. Peroxidase staining (no counter-staining) (× *c*. 830)

The tissue sections showed a well-reproducible and characteristic distribution pattern for cytochrome *c* in the different zones and along the individual nephrons. The activity was greatest in the thick, ascending limb of Henle's loop and in the proximal and distal convoluted tubules. In the glomeruli no activity could be demonstrated. In the collecting ducts, the 'dark' ('intercalated') cells gave a strongly positive reaction, best seen in the outer cortical zone. In the 'light' cells only some scattered blue precipitates appeared in the outer cortical zone.

The specificity of the reaction is of primary interest. The cytochemical localization of the peroxidase activity matches that obtained for the sub-cellular fractions of perfused rat kidney homogenates[8]. By this method the main peroxidase activity was found in the mitochondrial fraction. Other cytochromes (a_3, a_1 and b) do not interfere with the reaction, since the staining reaction is negative when the sections are washed in physiological saline prior to staining. Cytochrome *c* is the only cytochrome in animal tissues known to be extractable by saline[9]. This hæmoprotein could also be demonstrated in the saline washings by means of the peroxidase method[1]. Catalase shows no peroxidase activity in acid solution[10]. Thus, the histochemical method appears specific for cytochrome *c*.

I thank Prof. K.-G. Paul, Department of Medical Chemistry, University of Umeå, Sweden, for his advice, and Dr. A. Attramadal for help during the freeze-drying procedure.

PATHOLOGY

Adenosine Triphosphatase in Normal and Scorbutic Wounds

ASCORBIC acid deficiency produces well-known alterations in wound healing. Using histoenzymatic techniques important changes have been described such as a decrease in alkaline phosphatase[1] and a relative increase in acid phosphatase[2] in scorbutic wounds as compared with controls. With the technique proposed by Wachstein and Meisel[3] for the demonstration of adenosine triphosphatase a marked response appears in blood vessels. This investigation was carried out in order to examine adenosine triphosphatase-positive blood vessels in wounds performed in normal and scorbutic animals.

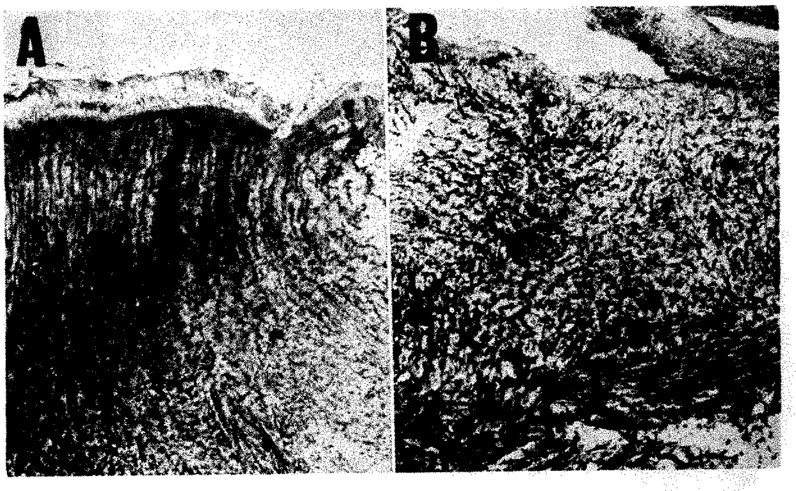

Fig. 1. Seven-day skin wound, Wachstein and Meisel technique, incubation time 3 h. *A*, Control animal; *B*, chronic scurvy

Twenty-five guinea pigs were divided into three groups: total deficiency (6 animals), partial deficiency (9 animals) and controls (10 animals). The diet used was that proposed by Nadel *et al.*[4] in a way similar to that described in a previous paper[2]. Wounds in dorsal skin and tongue were made and animals killed after three days and one week (total deficiency) and 3 days and 1, 2 and 3 weeks (partial deficiency and controls). The wound area with a wide margin of normal tissue was removed, fixed in 6 per cent formalin and processed according to the technique of Wachstein and Meisel.

In control animals an intense response was noted in blood vessels, especially those newly formed, and a moderate reaction in fibroblasts. The granulation tissue area was easily recognized for the abundance in blood vessels which adopted a characteristic pattern perpendicular to the wound surface (Fig. 1,*A*). This vascular orientation was observed until the wound became epithelized; at this time blood vessels appeared reduced in number and lost their orientation.

In vitamin C-deficient animals, adenosine triphosphatase appeared with the same localization and intensity as in controls, but a striking difference in distribution of blood vessels was observed. In as yet unepithelized wounds, a complete lack of orientation of blood vessels was noted, forming a reticular pattern (Fig. 1,*B*). This distribution of blood vessels was seen both in chronic and acute deficiency wounds. When the wound appears epithelized blood vessels were seen reduced in number and with an irregular distribution both in controls and deficient animals.

Effect of 2-Methyl-1,2-*bis*-(3-pyridyl)-1-propanone (Metyrapone) on the Production of Mammary Tumours induced in Rats by Oral Feeding with Dimethylbenzanthracene

THE oral administration to rats of 9,10-dimethyl-1,2-benzanthracene (DMBA) has become an accepted method of producing mammary tumours for experimental purposes[1]. This treatment has also been shown to cause massive adrenal necrosis[2] which can be prevented by simultaneous administration of 2-methyl-1,2-*bis*-(3-pyridyl)-1-propanone (metyrapone)[3]. This communication reports the effects of metyrapone on the incidence in rats of mammary tumours induced by oral DMBA.

Rats descended from stock imported from Sprague–Dawley of Madison, Wisconsin, and commercially available

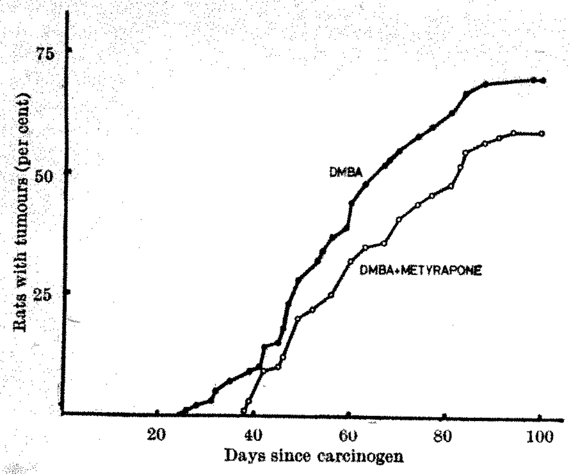

Fig. 1

in Britain, were used. A total of 440 rats was divided into two groups by a formal randomization process. In the first group each rat was given one subcutaneous injection of 40 mg of metyrapone in 4 ml. of corn oil, followed 12 h later by 50 mg of DMBA in 2 ml. of corn oil by intragastric tube. In the second group no metyrapone was given but each rat received the same dose of DMBA as in the first group. The DMBA was given on the 54th day of life. Three days after the administration of DMBA one-fifth of the rats from each group were killed by coal gas. The adrenals were dissected out, fixed in 10 per cent neutral formalin and embedded in paraffin. Sections were cut at 5μ and stained with hæmatoxylin and eosin.

Histological examination of the fixed and stained adrenals showed that only 3 out of 33 rats developed adrenal necrosis in the group receiving metyrapone + DMBA, in contrast to 31 out of 40 rats which developed massive adrenal necrosis in the group receiving DMBA alone. This supports the findings of Currie *et al.*[3], although the dosage of metyrapone in the present experiments differs from that previously reported.

During the 3 months after giving DMBA fewer rats developed tumours in the group given metyrapone + DMBA than in the group given DMBA alone, but the differences are not statistically significant. $P < 0{\cdot}2 > 0{\cdot}1$ (Fig. 1, Table 1). The difference, however, between the total tumours produced in each group by 100 days is just significant at the 5 per cent level (Table 2). It has been shown by Young and Cowan[4] that some of the tumours induced by orally administered DMBA stop growing while others regress spontaneously. The incidence of adrenal necrosis and the relative proportions of growing, static and spontaneously regressing tumours are given in Table 2.

It is clear that whereas metyrapone has almost completely prevented the occurrence of massive adrenal necrosis, it has not materially affected the induction period of tumours, the proportions of rats developing tumours, or the relative proportions of growing, static or spontaneously regressing tumours. It has, however, significantly reduced the total yield of mammary gland tumours in the group of rats to which it was given.

Table 1. NO. OF RATS DEVELOPING MAMMARY GLAND TUMOURS IN GROUPS GIVEN METYRAPONE + DMBA AND DMBA ALONE

	Days after DMBA	60		80		100	
Metyrapone + DMBA	Rats with tumours	22/69		33/69		41/69	
	Total tumours		27		68		90

Incidence of Squamous Cell Carcinoma in Mice fed 9,10-Dimethylbenz(a)anthracene

9,10-Dimethylbenz(*a*)anthracene (DMBA) has been used to induce neoplasms in experimental animals for some years[1]. However, the oral route of administering this compound has received little attention. Engelbreth-Holm and Poulsen[2] increased the incidence of leukæmia and mammary carcinoma at an early age, and Saxén *et al.*[3] induced carcinoma of the forestomach by feeding DMBA to mice of strain Street (then, not an inbred strain). Saxén[4] used irradiated *C57Br* mice for his DMBA feeding experiments. It was considered of interest to extend these observations on feeding DMBA under different experimental conditions and on other strains of mice. This communication reports the successful induction of neoplasms with a low total dose of the carcinogen. It gives the incidence and describes the pathological changes observed when *C57Br* and *C3H* mice were tube fed with a DMBA emulsion.

Two strains of mice, *C57Br* and *C3H*, were used in these experiments with about equal numbers of male and female animals in each group. A 30 mg per cent emulsion of 9,10-dimethylbenz(*a*)anthracene (DMBA) was prepared in 5 per cent 'Triton-100' (alkyl aryl polyether alcohol), a commercial surface-active emulsifier. The carcinogen was introduced into the stomach of mice with a polyethylene tube in 0·3 ml. feedings. A group of *C57Br* mice about 2 months old received 3 feedings a week for 10 weeks, a group of *C3H* mice about 6 months old received 2 feedings a week for 4 weeks and one feeding per week for 7 weeks, a total of 15 feedings in 11 weeks. Another group of *C57Br* mice, about 6 months old, received a single feeding of DMBA emulsion. Two groups of control mice of strain *C57Br* received 0·05 per cent 'Triton-100' in place of drinking water throughout the experimental period. One control group was one month old and the other eight months old at the start of the experiment. All the mice were fed a diet of Purina laboratory chow pellets, and examined at regular intervals to determine their general health, and for signs of developing lesions. An animal was killed when a lesion was suspected or when its general condition was poor. All mice were autopsied and specimens for histological examination were taken from each tumour mass and also from different parts of the stomach, intestine, spleen, kidney, liver and lungs. Tissues were fixed in Zenker-acetic or Zenker-formal fluids and embedded in paraffin. Microscopic sections were stained routinely with hæmatoxylin and eosin.

Tube feeding of 0·3 ml. of DMBA in 5 per cent 'Triton-100', 3 times a week, was well tolerated by mice. Feeding of 0·05 per cent 'Triton-100' in drinking water to control mice for 12–24 months showed no apparent deleterious effect on the general health. Some animals in every group receiving one or more DMBA feedings developed squamous cell carcinoma of the forestomach. In this work only those lesions were diagnosed as carcinomas which penetrated through all the layers of the forestomach wall. Others were diagnosed as precancerous or papillomatous lesions depending on their invasiveness The lesion of the forestomach of the mouse observed in this study is similar to the lesion induced in the mouse forestomach with methylcholanthrene and dibenzanthracene These lesions have been adequately described and illustrated by Stewart *et al* [5] and Firminger and Stewart[6] The incidence of squamous cell carcinoma in the forestomach of mice receiving various treatments and that survived over 100 days after the treatment was started is listed in Table 1 The incidence was 73 5 per cent in *C57Br* mice which received a total of 2 7 mg DMBA in 30 equal feedings, 40 5 per cent in *C3H* mice that received 1 35 mg DMBA in 15 feedings and 8 5 per cent in *C57Br* mice that received 90 μg DMBA in a single feeding There was no appreciable sex difference in the incidence of this tumour, however, 4 carcinomas appearing in the group receiving a single dose of DMBA were all in female mice

Table 1 INCIDENCE OF SQUAMOUS CELL CARCINOMA OF FORESTOMACH IN MICE FED 9,10-DIMETHYLBENZ(*a*)ANTHRACENE

Mouse strain	Sex	No	Doses	Total DMBA ingested (mg)	Duration (days)	Carcinomas No	%	
C57Br	M	22	30	2 7	245	15	68 0	73 5
C57Br	F	27				21	77 8	
C3H	M	24	15	1 35	245	10	41 7	40 5
	F	13				5	38 5	
C57Br	M	28	1	0 09	300	0	0	8 5
C57Br	F	19				4	21 0	
C57Br	M	10	*		256	0	0	3 0
	F	23				1	4 3	
C57Br	M	15	*		632	0	0	0
C57Br	F	36				0	0	

* 50 mg per cent 'Triton-100' in drinking water

One squamous cell carcinoma of the forestomach was observed in a female, in a group of 33 control mice, but there was no incidence of carcinoma in the second group of 51 control mice As animals in the second control group received 0 05 per cent 'Triton-100' for about 400 days more than the mice in the first group, it was concluded that the carcinoma in the first group was probably not caused by 'Triton-100' in the drinking water

Hyperkeratosis of the forestomach was common in most of the mice in both control and experimental groups However, the group of mice receiving a single dose of DMBA showed 3 (6 4 per cent) precancerous lesions and 14 (29 8 per cent) papillomas, while all mice in both control groups showed no precancerous lesions and only 5 9 per cent papillomas

The vehicle, 'Triton-100', used for DMBA administration and fed in drinking water to control mice, is one of a series of compounds with predominantly hydrophylic properties and demonstrated power of strong penetration in the glandular mucosa of the stomach[7] Control mice received a maximum total dose of over 3 ml of the vehicle per mouse during the experimental period This dose of 'Triton-100' did not induce any abnormal changes in the forestomach or glandular stomach of the mouse The maximum dose of 'Triton-100' received by an experimental mouse was only 0 45 ml

In the feeding experiments of Lorenz and Stewart[8,9], the range of carcinogenic hydrocarbon ingested by a mouse during the experimental period was about 100–250 mg of methylcholanthrene or dibenzanthracene in olive oil emulsion[8] and 50–200 mg of the same hydrocarbons in mineral oil emulsion[9] Engelbreth-Holm and Poulsen[2] were the first to tube-feed DMBA to mice They used a glass tube and probably because of trauma to the œsophagus only 68 of 175 mice survived to be 4 months old Total DMBA administered per mouse was 2–6 mg They did not report any forestomach lesions in their mice Saxén *et al* [3] working with Street II strain mice administered a total DMBA dose of 0 3–4 mg by polyethylene tube They found forestomach carcinomas in 3 out of 9 mice receiving 0 6 mg (600 μg) as a total DMBA dose, but no carcinomas in mice receiving 300 μg of DMBA Under my experimental conditions a single dose of 90 μg DMBA administered orally gave undisputed evidence of the induction of carcinoma Induction of neoplasms in 10 per cent of mice by a dose of a fraction of a microgram of carcinogen (0 08 μg of dibenz(*a,h*)anthracene subcutaneously to 12 h old mice) was recently reported by O'Gara *et al* [10]

I thank Dr H L Stewart for help with the histopathology work

Tumour-enhancing Activity of the Active Principles of *Croton tiglium* L.

THE potent tumour-enhancing agent croton oil (from the seed of *Croton tiglium* L) has been used for many years in biological investigations of the cause of cancer[1,2] and several unsuccessful attempts have been made to purify and to describe chemically the active components[3,4] The isolation and chemical structure elucidation of pure compounds which are active tumour-enhancing agents is important since it will facilitate new and definitive studies on the mechanisms of carcinogenesis and co-carcinogenesis

We described recently the chemical constitution of a crystalline product obtained by catalytic hydrogenation of the tumour-enhancing fraction of croton resin[5] This material, which is a fatty acid ester of a polyphenol, was shown to be very similar to the active materials in its chemical constitution

The notable biological activity of some materials obtained from the active mixture of compounds are described here The isolation of these compounds is described elsewhere[5]

All materials were tested by skin-painting on female Swiss Millerton mice. The animals were first given a single application of 7,12-dimethylbenz(*a*)anthracene (DMBA) applied in acetone solution by micro-pipette The dose of carcinogen applied (150 or 300 μg) was at such a level that it did not by itself give any skin tumours The primary treatment was followed 14 days later by three-times weekly applications of promoters

In the first test, 18 animals were used in each group; 150 μg DMBA was used as initiator The promoters were applied three times weekly, 25 μg dissolved in 100 mg acetone per application, applied on the clipped mouse skin with a Number 5 camel hair brush The results are shown in Fig 1 In this experiment the vesicant fraction, croton resin, prepared as described by Cherbuliez[6], is compared with a column-chromatographic fraction derived from it and the whole croton seed extract Concentration of activity was achieved in the croton resin and its sub-fraction Control groups, also with 18 animals per group, included animals which received DMBA only, promoters only, solvent only, and a group which received no treatment One animal with a papilloma was observed in each of the two control groups which received only croton resin or its sub-fraction

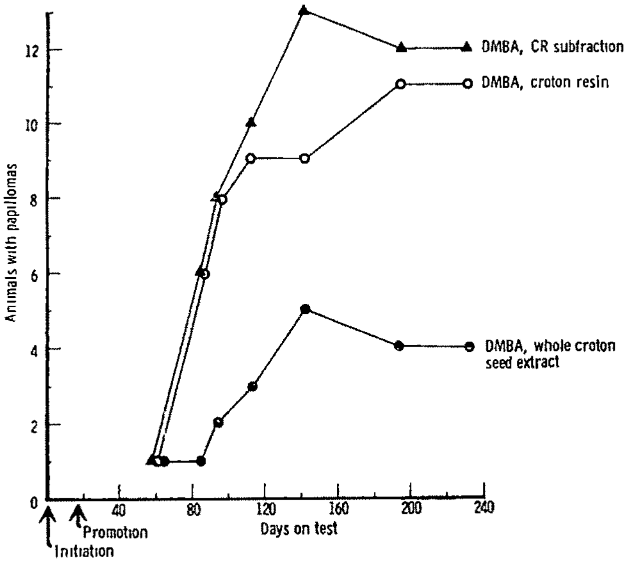

Fig 1 Tumour promotion by croton seed extract and fractions derived from it

Malignant tumours were observed in the promotion experiments with croton resin and its sub-fraction as early as 100 days after initiation At the end of one year, 70 per cent of the surviving animals which had received DMBA followed by croton resin had squamous cell epidermoid carcinomas These were usually situated at the sites of previous papillomas None of the animals in the control groups showed malignant tumours at the end of one year

Histological examination of papillomas showed proliferative changes in the epidermis with marked keratinization, acanthosis and intact basal layer Histological examination of the epidermoid carcinomas showed marked atypia of epidermal cells, mitoses, keratin pearls and break-through of the basal layer Sheets and clumps of tumour cells were present in the subcutis

Progressive purification of the biologically active mixture led to two components, labelled *A* and *C*, which showed single spots on thin-layer chromatograms[5] Both these materials are powerful irritants and showed high tumour-enhancing activity as shown in Table 1 Twenty female Swiss Millerton mice were used in each of the two groups A single dose of DMBA, 300 µg in 0 15 ml acetone, was given to each animal After a 2-week interval the animals in one group received three times weekly paintings of *A* and the other received *C*, 5 µg material was applied in 0 1 ml acetone per application

The control groups, 20 animals per group, were as follows (1) a group which received a single application of 300 µg DMBA in 0 15 ml acetone, (2) a group which received three times weekly applications of promoter *A*, 5 µg in 0 1 ml acetone per application, (3) the same as (2) but with promoter *C*, (4) a group which received applications of acetone three times weekly, 0 1 ml per application, (5) a group which received no treatment Tumours were not observed in any of these control groups

The level of activity of compounds *A* and *C* is much higher than that reported for other tumour-enhancing agents such as phenol[7], the 'Tweens' and 'Spans'[8] With 'Tween 40', for example, 60–80 mg of material was applied per animal, six times weekly[8] This is roughly 30,000 times the weekly dosage of compounds *A* and *C* used in the present work In the interpretation of the work on 'Tween' and related materials the presence of small amounts of active impurities cannot be overlooked since massive doses were applied

Table 1 Tumour Promotion with Compounds *A* and *C* No of Animals with Tumours*

Weeks†	4	5	8	14‡

Cumulative weight of promoter applied per animal (µg)	60	75	120	210

* All tumours were benign papillomas and were confirmed microscopically
† After beginning of promotion
‡ All animals were alive after 14 weeks

In another experiment two groups of 18 animals each received an initiating dose of 150 µg of DMBA After one year without further treatment the eleven survivors of one of the groups received paintings three times weekly with 25 µg of croton resin dissolved in 100 mg of acetone per painting The second group of fourteen survivors served as an untreated control Within 37 days from the beginning of painting with croton resin two out of eleven animals developed papillomas and, after 120 days, 4 animals had papillomas and two had squamous cell epidermoid carcinomas Skin tumours were not observed in the control group This experiment confirmed an earlier experiment of Berenblum[2] in which 10 months was allowed to elapse between initiation and promotion.

IMMUNOLOGY

Duration of Antibody Response to Soluble Antigen: Incorporation of Sulphur-35 Methionine into Normal and Antibody Globulin

We recently reported[1] that precipitating antibodies were present in chicken serum more than 300 days after two spaced intravenous injections of bovine serum albumin Antibody remains detectable at 470 days post-injection with no apparent decrease in concentration having occurred over the last 300 days It is of theoretical interest to know if these antibodies represent the product of continued synthesis, approximating a steady state, or alternatively reflect the gradual release from tissue depots of antibodies synthesized at a much earlier time The present communication provides evidence favouring the former hypothesis

Two chickens were injected intravenously with 1 mc each of ^{35}S-L-methionine (12 mc /m mole), 470 days after the second injection of bovine serum albumin Serum samples obtained both before and after injection of sulphur-35 were dialysed against three changes of buffer (0 1 M *tris*, 0 1 M sodium chloride, *p*H 8 0) containing unlabelled L-methionine (0 01 M) followed by dialysis for several days against large volumes of buffer without methionine The antibody content of the samples was then estimated by the method of Talmage and Maurer[2] using bovine serum albumin labelled with iodine-131 to determine where 80 per cent of the added bovine serum albumin was precipitated (*P*-80) Disodium ethylenediamine tetraacetate (EDTA) was added to a final concentration of 0 01 M in order to eliminate, in so far as possible, coprecipitation of non-antibody protein. A *P*-80 for chicken 30 was 0 35 µg bovine serum albumin nitrogen/

ml., for chicken 28, 0.9 µg bovine serum albumin nitrogen/ml. Antibody concentrations of these samples would be (P-80 × 5.5) about 2 and 5 µg nitrogen/ml. respectively. Determinations of specific activity were made on 1 ml. aliquots of serum incubated with the P-80 concentration of bovine serum albumin. Tubes were incubated at 37° for 2 h and then at 5° for 4 days. Precipitates (barely visible in the case of chicken 30) were washed three times with cold buffer containing EDTA and then dissolved in 0.4 ml. of 0.1 N sodium hydroxide. Protein nitrogen determinations[3] were carried out with 0.2 ml. of the solution removed carefully with a Lang-Levy micropipette. The remaining 0.2 ml. was analysed for radioactivity in a liquid scintillation counter (Packard, 'Tri-carb'). Determinations of the specific activity of 'normal' globulins, that is, proteins insoluble in one-half saturated ammonium sulphate, were carried out in similar fashion.

The contribution of non-antibody protein to precipitates was calculated from the radioactivity found in precipitates of a heterologous chicken immune system (pea seed globulin, anti-pea seed globulin). Antibody and antigen were first dialysed against buffer and then added in equivalence proportions (with EDTA) to triplicate 1-ml. serum samples. The antibody content of the precipitates formed was similar to the bovine serum albumin system. Tubes containing serum and buffer alone were also assayed. The latter contained no detectable protein (less than 0.2 µg nitrogen) and had essentially background radioactivity. By contrast, no more than 0.2 µg nitrogen coprecipitated with each µg antibody nitrogen in the heterologous system, despite the presence of EDTA. It is assumed that this applies equally to the bovine serum albumin system.

Even after subtraction of the contribution of non-antibody protein to precipitates, considerable activity remained: this is attributed to antibody (Table 1). At least 50 per cent of the estimated antibody content of precipitates would have to be non-specific protein (having the same specific activity as the normal globulins) in order to account for the total radioactivity present. In addition to the data from the heterologous precipitin system, the close agreement of calculated antibody concentrations (P-80 × 5.5) with protein determinations using the Folin phenol reagent[3] argues against such gross contamination.

* All values based on 10-min counts.
† 21 per cent of the specific activity of normal globulins for chicken 30, 28 per cent for chicken 28.

The ratios of specific activities, antibody to normal globulin, were reasonably constant over the time interval tested, ranging from 25 to 40 per cent for both chickens (Fig. 1). The significance of specific activity differences between normal globulins and antibody is not clear. This is in part because of the heterogeneity of the globulin fraction. However, it has been shown[4] that during the initial phases of antibody responses the specific activity of antibody may be 2–3 times higher than the remaining globulins. If the bulk of the globulin fraction represents antibody synthesized during recently initiated immune responses, then the lower specific activity of late antibody is predictable. The results do not permit a confident estimate of the half-lives of antibody; however, assuming they do not differ markedly from those of normal globulins, values of 60 h (No. 30) and 75 h (No. 28) are obtained. This agrees well with other estimates in chickens[5].

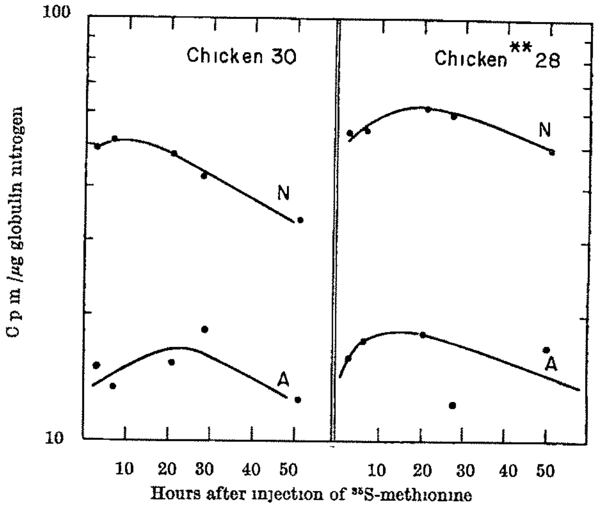

Fig. 1. Incorporation of ^{35}S-methionine into antibody (A)* and normal globulins (N)

* Corrected for non-specific protein

** Original values multiplied by 2

In view of the long-continued active synthesis of antibody, any theory requiring a direct role of antigen in antibody synthesis must obviously require also prolonged storage of antigen or specific fragments in relevant cells.

Radiation Protective Effect and Pharmacologically Changed Activity of the Reticulo-endothelial System

BACTERIAL endotoxins, zymosan and other complex polysaccharides are stimulants of the reticulo-endothelial system[1,2]. This follows from the enhanced phagocytic activity as measured by the rate of removal from the blood of intravenously injected carbon[3]. But these substances also have a radiation protective effect, as has been found with mice, rats and hamsters[4]. Therefore, it is accepted that this radiation protective effect is causally connected with the enhanced activity of the reticulo-endothelial system and that, in general, the radiation resistance of an organism with an augmented activity of the reticulo-endothelial system is greater than with a normal activity state of this unspecific defence system[5]. This concept is in agreement with the conjecture that the prime cause of death after whole-body X-irradiation depends primarily

on the exhaustion of certain cells originating in the reticulo-endothelial system[6]

It this concept were correct then naturally not only should the mentioned agents alone have the ability to increase the radiation resistance (protective effect) but also other methods of stimulation of the reticulo-endothelial system should act in the same way Likewise, depression of the reticulo-endothelial system would be expected to decrease the radiation resistance This concept is apparently contradicted by the finding that ethyl palmitate, a compound known to depress reticulo-endothelial system phagocytic activity, exerts a protective effect on X-irradiated mice[7] The high doses of ethyl palmitate which were used in these experiments, however, did not affect exclusively the reticulo-endothelial system but also led to a severe damage to the parenchyma of the red and white pulp of the spleen[8] Consequently, they are not suited for the assessment of the relations between the reticulo-endothelial system and the biological radiation effect But this is also the same for the reticulo-endothelial system stimulants already mentioned, because they also are said to exert complex reactions in the liver and the spleen, in which lymphocytes and plasma cells are engaged[2] Therefore, it seems desirable for the elucidation of the relations between activity of the reticulo-endothelial system and radiation resistance to utilize in further experiments only those substances which exert a specific and easily controllable alteration of activity of the reticulo-endothelial system using the already mentioned carbon clearance method[3] These requirements are met by some simple lipids[2] As several substances of this group stimulate the activity of the reticulo-endothelial system and others depress it, their application enables us to compare the influence of stimulation and depression of the reticulo-endothelial system on the biological effect of radiation

I used male white mice of an inbred strain of this laboratory , age 8–10 weeks, weight 18–23 g A small number of the animals was taken to measure the activity of the reticulo-endothelial system at the time of irradiation By far the greatest number was X-irradiated 24 h after the injection of lipids and 30 days later the survival rate was established The reticulo-endothelial phagocytic function was evaluated by measuring the intravascular removal rate of intravenous injected colloidal carbon (phagocytic index K)[3] Whole-body X-irradiation with 610 r , dose rate 90 r /min , 200 kV, 15 m amp , filtration of 0 43 mm copper, half-value layer 0 87 mm copper , focus-target distance of 40 cm For stimulation of the reticulo-endothelial system, I used olive oil, triolein, 2-oleo-distearin and tricaprin , for depression of the reticulo-endothelial system ethyl stearate, ethyl oleate, cholesterol oleate and such small doses of ethyl palmitate which indeed injured the phagocytic function of the reticulo-endothelial system but not the parenchymatous tissue of the spleen[2,9]

Table 1 presents the following experimental results

First Phagocytic activity The statements in the literature concerning alteration of the reticulo-endothelial system by the examined lipids were confirmed with my mouse strain. Olive oil, triolein, 2-oleo-distearin and tricaprin stimulated the phagocytic activity 24 h after injection, but ethyl palmitate, ethyl stearate, ethyl oleate and cholesterol oleate depressed it at this time

Second Survival rate All lipids mentioned, both those which stimulate and those which depress the reticulo-endothelial system, exerted a protective effect against X-rays It is remarkable that the depressing agents were mostly more effective than the stimulating agents

The results of these experiments confirm that with mice it is possible to stimulate or to depress the phagocytic activity of the reticulo-endothelial system by intravenous injection of simple lipids These lipids, furthermore, exert a protection effect against X-rays which differs from one substance to another The degrees of alteration of the phagocytic activity and of the radiation sensibility did not always parallel each other Thus, a radiation protection effect was obtained with lipids whether or not their action on the function of the reticulo-endothelial system was one of stimulation or depression It seems clear that the concept of enhanced activity of the reticulo-endothelial system as a factor of importance for the survival of mice after irradiation is in need of revision Perhaps an alternative idea is that cells of the reticulo-endothelial system engaged in the metabolism of simple lipids as described are more resistant to radiological injury than usual

I thank Dr A E Stuart, Department of Pathology, University of Edinburgh, who kindly demonstrated the carbon clearance technique, and Dr C B Barret of the Unilever Research Department, Port Sunlight, Cheshire, who kindly supplied the 2-oleo-distearin

RADIOBIOLOGY

Cæsium-137 in the Blood of the Finnish Lapps

About 2,500 Lapps live in Finnish Lapland, and, as has been shown by an investigation carried out in October 1961 [1], the elevated radioactivity in them is principally due to the high cæsium-137 content of the reindeer meat which constitutes their main food. In May 1962, a second, wider survey of the body burden of cæsium-137 and of the diet and health of the Lapps was carried out[2]. The subjects, some 200 Lapps of ages ranging from 20 to 50, were selected in advance by the random sampling method from the church register. About 90 per cent of those summoned responded to the invitation. This investigation revealed that the body burden of cæsium-137 in Lapps was on the whole twice as high as in October 1961[1-3], but no correlation between the cæsium-137 content and the findings of medical examination could be observed[2,4,5].

The Lapps provide a unique opportunity to determine the correlation between cæsium-137 content of blood and whole body in a population living in natural conditions. Therefore, 20 ml. blood samples were taken in the foregoing investigation from all adults examined (102 men and 52 women), for cæsium-137 analyses[6]. The samples were transported in ice to the laboratory and ashed carefully at 400° C in order to improve the counting efficiency. The activity was measured in a sodium iodide (Tl) well-type crystal with a Nuclear Chicago model 132 *A* one-channel analyser in the range of the cæsium-137 peak between 612 and 712 keV.

The counting system was calibrated with Radiochemical Centre, Amersham, cæsium-137 reference solution *CDR* 4 in inactive calcium carbonate. A counting efficiency of 9.4 per cent was achieved for cæsium-137 in the range concerned. The background measured in the corresponding range was on the average 14.15 ± 0.15 c.p.m. during the course of the measurements. The number of impulses in the cæsium-137 range caused by potassium in the blood did not differ from the statistical fluctuations of the background during the measuring times used. Therefore, no correction was made. By measuring all blood samples simultaneously placed around a 5 in. × 3 in. Harshaw crystal, with a multi-channel pulse height analyser for 1,000 min, it was seen that they did not generally contain any observable amounts of other γ-emitters (Fig. 1).

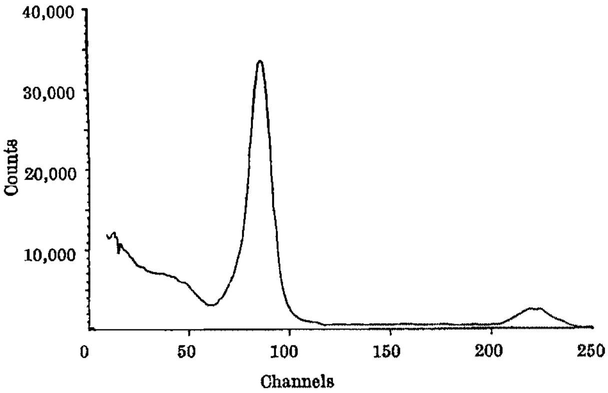

Fig. 1. Pooled blood samples, a net spectrum in 1,000 min

A graphic presentation of the whole-body values[2] in nc (10^{-9} c.) plotted against the pc (10^{-12} c.) values calculated for a litre of blood shows the correlation between them (Figs. 2 and 3). The correlation coefficient differs significantly from zero, the value for the male subjects being $r_{xy} = 0.83$ and that for the females $r_{xy} = 0.84$. By means of regression analyses the best straight line passing through the origin was fitted to the points, and the corresponding ranges of variation at the 95 per cent confidence-level were calculated. Since the graphs in Figs. 2 and 3 showed that there are some values which deviate considerably from the regression line, the ranges of variation for the individual observations were calculated as well. To make the regression line pass through the origin is to assume that when the whole-body value is zero the blood value is also zero and vice versa. However, this is not necessarily true. Therefore, an equation for a regression line which was not made to pass through the origin was derived from the data, also. The equations are given in Table 1.

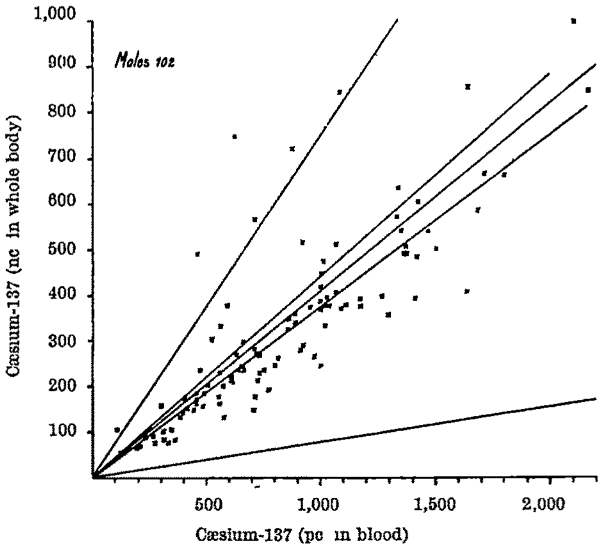

Fig. 2. Graph showing the correlation between the body burden of cæsium-137 (nc) and the cæsium-137 contents of blood calculated in pc./l. (males)

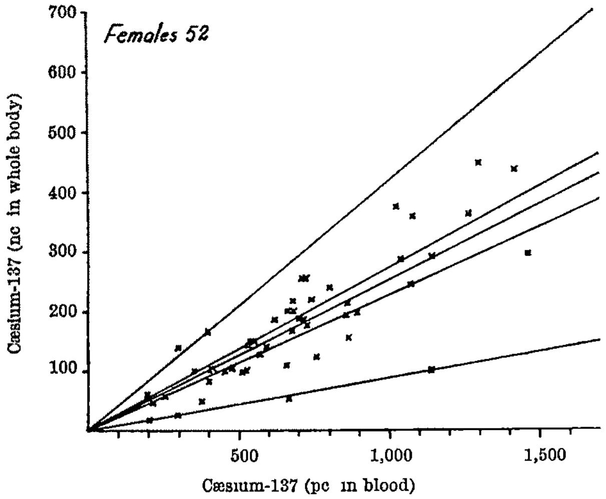

Fig. 3. Graph showing the correlation between the body burden of cæsium-137 (nc.) and the cæsium-137 contents of blood calculated in pc./l. (females)

Table 1. Equations of the Regression Lines

	Males		Females	
	Through the origin	General	Through the origin	General
Regression line	$y = 0.41\,x$	$y = 0.37\,x + 21$	$y = 0.25\,x$	$y = 0.27\,x - 12$
Corresponding ranges of variation at the 95% confidence-level	$y = 0.38\,x$ $y = 0.44\,x$		$y = 0.23\,x$ $y = 0.27\,x$	
Ranges of variation for the individual observations at the 95% confidence-level	$y = 0.08\,x$ $y = 0.74\,x$		$y = 0.09\,x$ $y = 0.41\,x$	

To describe the relationship between the cæsium-137 values of the blood and the whole body a straight line was used in this range, since the possible bending of the describer with higher cæsium-137 values could not be observed owing to the insufficient number of high values

As can be seen from the equations, the slopes of the lines passing through the origin do not deviate greatly from the slopes of the corresponding lines not passing through the origin. Neither can the intercepts be said to deviate significantly from zero when the errors of both activity measurements and the detection limits of the measuring systems are taken into account

It may be noticed that the slopes of the lines for males and females differ from each other This might possibly be ascribed to the differences in the excretion of cæsium in males and females

The subjects, in whom the ratio of whole-body value and blood value deviated from the regression line by more than 30 per cent, were examined in the light of the results of the medical examination and the dietary survey[2] In the comparisons there was nothing exceptional either in the findings of the routine health examination or in the food consumption habits of the subjects concerned In the literature, large individual differences in excretion of cæsium have been reported Half-times are given as 50–160 days A small fraction of the cæsium has been observed to be excreted considerably faster than the remainder[7] These facts could possibly explain the values that deviated considerably from the regression lines

On the basis of the results obtained it can be concluded that the whole-body burden of cæsium-137 can be estimated with sufficient reliability from the blood content of radiocæsium when the cæsium-137 values are 200–1,500 pc /l blood, and when the survey concerns the cæsium-137 burden of a group of people whose recent dietary history is known

We thank the Finnish Atomic Energy Commission for financial aid, and Dr Esko Kaila for the statistical calculations

Influence of Radio Frequency Heating on Sperm

THE influence of temperature on the survival of spermatozoa *in vitro*[1] and the influence of high temperatures on the reproductive capacity of guinea pigs' spermatozoa have been investigated[2] by many workers

The work recorded here was undertaken to examine the influence of radio frequency heating on sperm in the genital passage of the female rabbit immediately after copulation The number of young born and the average litter size were the criteria used to assess the effect

Radio frequency heating, widely used in diathermy, has no side effects on tissue if the period of treatment and temperature gradient are kept within safe limits In particular, it is known that repeated elevation of the body temperature by radio frequency heating is innocuous to the functioning of the reproductive organs[3–5]. Also, greater uniformity and heat penetration in tissue are obtained than by heating elements or pads

The radio frequency electric field was set up between a plastic-coated metallic probe electrode (¼ in diam × 5 in), which was inserted in the genital passage, and a pad electrode (6 in × 8 in) on which the abdomen of the rabbit was resting Temperatures of 43 2°–45° C could be easily realized, the latter usually in the close neighbourhood of the bony tissue of the pelvic inlet

Six Albino rabbits were used as controls and six were treated in the three series of studies undertaken When the young from the first series were weaned, treated and control groups were reversed and were used in the second series When the young from this investigation were weaned 7 animals that had delivered young in the two previous series were treated and used for the final group The total number of treated animals was therefore 19 Two vigorous males of known fertility were used alternately throughout

Immediately after breeding a vaginal swab was taken to establish the presence of sperm The female was then lightly anæsthetized to facilitate manipulation of the probes and to avoid undue movement and possible injury to the animals during treatment Pre-treatment vaginal temperatures were recorded and then the probe electrode was inserted into the vagina for a depth of approximately 4 in A temperature probe connected to an electronic thermometer was placed in the vagina aside and to the same depth as the electrode The pad electrode was placed so as to be directly under the abdominal and pelvic organs The probe and pad electrodes were connected to a diathermy generator the output of which was then adjusted so that vaginal temperature rose to above 43 2° C as quickly as possible (about 1 min) and treatment temperature was held at 43 2°–45° C for 10 min The generator was switched off whenever a temperature reading on the electronic thermometer was required In this way temperatures devoid of interference from the diathermy were obtained Procedure for control groups was identical to treated groups except that the diathermy machine was not switched on

Three animals did not conceive when used as controls or when treated These animals were discarded and the total number used as controls was therefore 9 and as treated 16

It was found that diathermy treatment reduced the litter size with respect to the total number of animals bred but did not alter the average litter size in animals that reached parturition (Table 1) All animals born appeared normal at weaning time and developed in a manner similar to controls These findings are in accord with the studies by Young in guinea pigs[2]

Table 1 INFLUENCE OF RADIO FREQUENCY HEATING ON PARTURITION COMPARISON BETWEEN CONTROL AND TREATED FEMALE RABBITS

Group	No bred	No of parturitions	% Bred reaching parturition	No of young	Litter size per animal bred	Average litter size per parturition
Control	9	8	88 8	45	5	5 6
Treated	16	5	31 2	27	1 7	5 4

The average litter size over a 1-year period in our breeding colony is 4–5 This average was approximated in the controls used in this study, which would suggest that the manipulations (administration of anæsthetic, insertion of probe, etc) did not contribute to the reduction in litter size in the treated animals

The possibility that reduction in the number of pregnancies was due to effects of heat on ovulation has not been excluded. This work does not permit the assessment of such a possibility.

Effect of Gamma-radiation on Eggs of the Silkworm

The need for biological information on the effects of extraterrestrial conditions encountered in space environments has recently been presented by Reynolds[1]. Techniques for the conduct of biological experiments in space studies are almost non-existent.

One factor encountered in space flight which is of significant importance to biological material is ionizing radiation. Previous work with *Drosophila* larvæ[2], house-flies (*Musca domestica* L.) and oriental rat fleas (*Xenopsylla cheopis* (Rothschild)) in various stages of development[3] failed to demonstrate any genetic effects after exposure to cosmic radiation at 70,000–82,000 ft. for 16 h. These results may have occurred because no cosmic ray 'hits' on the biological material were made or lethality was induced at low levels which was not measurable. Investigations have since been conducted to find a more suitable organism which could be used in space studies to record accurately the effect of cosmic and other radiations on biological material. Eggs of the silkworm (*Bombyx mori* (L.)), genetically well understood, possess many desirable biological characteristics necessary for investigations of this type. They are extremely light in weight, and require no food or water and only minute amounts of oxygen. In addition, the eggs are laid in a solid, single layer.

Their large size (1 mm), as compared with some insects, makes them a suitable target for 'hits' from heavy nuclei of the primary cosmic radiation. Dutky and Sullivan (unpublished report) have adapted a nuclear emulsion envelope suitable for the detection of such 'hits' on eggs and bacterial spores in space flight. The need for background information concerning the radiation sensitivity of silkworm eggs was recognized.

This communication describes laboratory investigations of the effects of γ-radiation on silkworm eggs in different stages of post-diapause development. The effect of fractionated radiation exposures was also investigated, since the total radiation dose delivered in space flight may not occur in a single exposure.

Freshly laid silkworm eggs (yellow variety) on filter paper were placed in a constant-temperature cabinet (27° C, 90 per cent relative humidity) for 4 days. They were then removed to a refrigerator (5° C), allowed to remain there for about 5 months, and then transferred to a cabinet held at 27° C to break the diapause condition and induce embryonic development. At 1, 4, or 7 days after the termination of diapause, eggs were exposed to a series of γ-radiation doses of 0·8 kr.–51·2 kr. The source of radiation was a cobalt-60 unit, which delivered approximately 320 r./min. Eggs 1 day in post-diapause development were also exposed to fractionated doses of 1, 2, or 4 kr. of total radiation for one exposure period, for two exposure periods of half the total dose each (the second exposure was delivered 90 min after the first), or for four exposure periods of a fourth the total dose, each at 90-min intervals.

After treatment the eggs were returned to the incubator and again held at 27° C. Hatching occurred in 9–12 days and mortality was determined in 14 days. Dosage-mortality curves were derived by the logit method of Berkson[4].

Silkworm eggs in early stages of post-diapause development were more susceptible to γ-radiation than eggs in the later stages of post-diapause development (Table 1). Exposure to 3·2 kr. of γ-radiation killed 100 per cent of the 1-day post-diapause eggs but only 50 and 5 per cent, respectively, of eggs at 4 or 7 days of post-diapause development. Similar results were obtained after exposure to 1·6 kr., but the differences were smaller. Mortality of 1- or 4-day post-diapause eggs increased with increasing exposure to γ-radiation, whereas mortality of 7-day post-diapause eggs did not increase significantly within the 0·8- to 3·2-kr. range.

Table 1. Per Cent Mortality of Silkworm Eggs exposed to Gamma-radiation 1, 4, or 7 Days after Termination of Diapause

Radiation exposure (kr.)	1 Day	4 Days	7 Days
None	8 *ab**	8 *ab*	8 *ab*
0·8	13 *ab*	12 *ab*	18 *b*
1·6	37 *c*	18 *b*	5 *a*
3·2	100 *e*	50 *d*	5 *a*

* Means not followed by the same or common letter are significantly different.

Table 2

Days in post-diapause development	Lower limit	LD_{50} (r.)	Upper limit
1	1,403	1,528	1,664
4	3,350	3,565	3,774
7	22,190	24,840	27,800

The dosage-mortality curves of 1, 4, and 7-day post-diapause eggs are shown in Fig. 1. These results are similar to those discussed. The LD_{50}'s of radiation derived from these results are shown in Table 2.

Total exposures of 0·8 or 1·6 kr. delivered in 1 irradiation period or 2 irradiation periods with half the total dose administered at a time were equally damaging to silkworm eggs in the 1-day post-diapause developmental stage (Table 3). A total exposure of 1·6 kr. delivered in fractions of a quarter of the dose at intervals of 90 min was less damaging than the same radiation dose administered in 1 or 2 irradiation periods. Exposure to 3·2 kr.

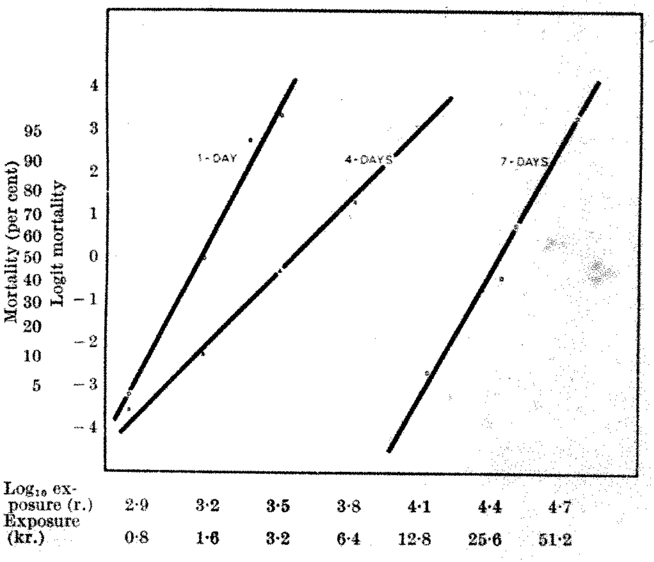

Fig. 1. Radiation dosage-mortality curves of silkworm eggs in 1, 4 or 7 days of post-diapause development

Table 3. PERCENTAGE MORTALITY OF SILKWORM EGGS EXPOSED 1 DAY AFTER TERMINATION OF DIAPAUSE TO SINGLE EXPOSURES OF GAMMA-RADIATION OR SEVERAL EXPOSURES AT 90-MIN INTERVALS

Total radiation (kr.) exposure	1 Exposure	2 Equal exposures	4 Equal exposures
None	8 *a**	8 *a*	10 *a*
0·8	14 *a*	13 *a*	13 *a*

BIOLOGY

Central Nervous Responses to Chemical Stimulation of a Gastropod Osphradium

THE function of the osphradium, a structure within the mantle cavity of many molluscs, has been the subject of some speculation. It is generally accepted to be a sense organ, but the modality to which it is sensitive remains obscure. Two major theories have been proposed. The first is that it is a chemoreceptor involved in food location. Copeland[1], Wölper[2] and Brown and Noble[3] have shown, by means of behavioural studies, that certain species of carnivorous gastropod depend on an intact osphradium and associated nerve supply for their ability to follow the chemical trail emanating from food material. Extirpation of the organ or section of the innervation leads to the loss of this attribute.

The second theory is that proposed by Hulbert and Yonge[4] and Yonge[5]. They suggest that the osphradium is "a tactile organ concerned with estimating the amount of sediment carried into the mantle cavity". This theory is based on the occurrence and development of the organ in a wide variety of gastropods in relation to their habitats.

In his recent review of gastropod chemoreception Kohn[6] states that Yonge now considers that a chemosensory role of the osphradium may have evolved secondarily from the original particle detecting mechanism.

The only direct physiological investigation carried out so far seems to be the attempts of Kohn[6] to record electrical activity from the osphradial nerves of *Busycon* after stimulating the osphradium with chemicals. This was unsuccessful. In the present work on *Buccinum undatum*, experiments using platinum wire electrodes to record from the osphradial nerves have failed, as have attempts to record from the osphradial ganglion that is situated along the mid-line of the organ. The nerves supplying the osphradium and part of the ctenidium arise from the supra-œsophageal ganglion, whence it has proved possible to monitor nervous activity by means of indium-filled glass micro-electrodes. In this way single units or, more frequently, small groups of units could be located and displayed by conventional means.

It is unlikely that these records represent the response of primary sensory neurones although these may pass directly through the ganglion[7]. It is more probable that they are interneurones or motor neurones. This central activity is, however, modified by stimulating the osphradium when the supra-œsophageal ganglion is isolated from the remainder of the central nervous system, leaving only the peripheral nerves to the osphradium and ctenidium intact.

Manual stimulation of the osphradium by means of a paintbrush or glass rod usually invoked activity although in most cases a large distortion was needed to elicit the response. If the organ does function as a sediment detector it must have mechanoreceptors of high sensitivity. To test this possibility, suspensions of 'Carborundum' particles (20–200μ diam.) in sea-water were run over the organ. This failed to elicit activity. Similarly sea-water adjusted to *p*H values in the range 3–9, and in concentrations between 50 and 150 per cent also failed to elicit nervous responses.

Volleys of action potentials were seen frequently in response to stimulating the osphradium with sea-water in which minced *Mytilus* had been left to stand. Such extracts invoked responses which often lasted for more than 30 sec (Fig. 1*C*). Attempts to mimic these responses with synthetic chemicals were successful only in the case of a neutral solution of 10^{-3} M *l*-glutamic acid hydrochloride in sea-water. A much less prolonged response was noted when a neutral solution of 10^{-2} M trimethylamine oxide hydrochloride was applied to the osphradium. Other chemicals, including betaine, glycine, alanine, glutamine and lactic acid, were also without effect.

Removal of the osphradium, with little damage to the remainder of the mantle, abolished the chemical responses of the preparation. In some cases, however, mechanical distortion remained an effective stimulus, the response

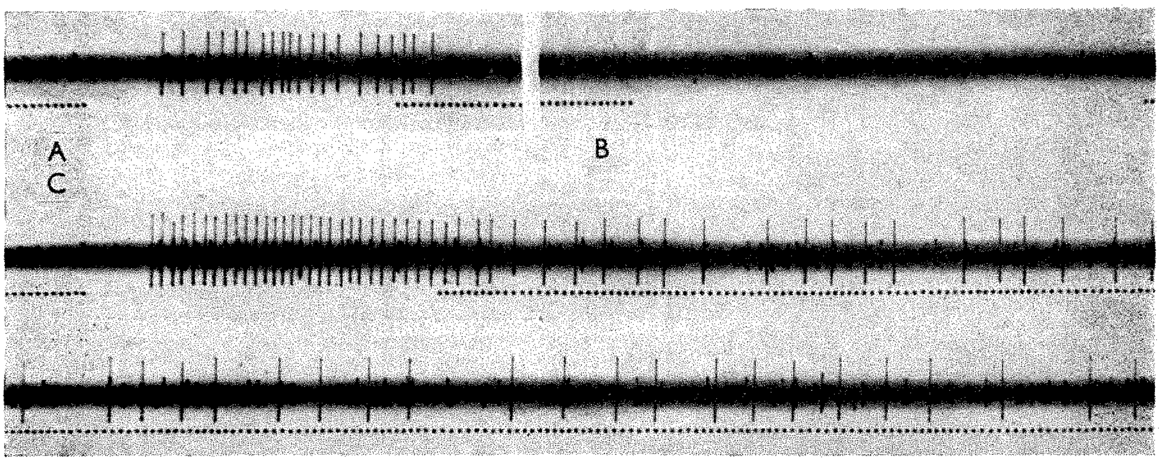

Fig. 1. Record of activity from the supra-œsophageal ganglion in response to stimulation of the osphradium. *A*, Response to touch; *B*, response to the application of sea-water; *C*, response to *Mytilus* extract in sea-water. Lines 2 and 3 are continuous. Time-marks = 10/sec. Duration of the stimulus indicated by the interruption of the time-marks

being mediated by sense organs located in the mantle musculature. This indicates that sensory pathways of several modalities located in the mantle region converge on units in the supra-œsophageal ganglion.

These results support the theory of chemoreception as a function of the osphradium at least in *Buccinum undatum*. Failure to record activity in response to light tactile stimulation suggests that the osphradial mechanoreceptors, if any, are insufficiently sensitive to act as sediment detectors as suggested by Hulbert and Yonge. During the course of the experiments it has been noted that copious production of mucus occurs from the hypobranchial gland, osphradium and mantle surface. This must severely impede the entry of particles into the mantle cavity in the natural situation and their contact with any part of the mantle surface.

Suppression of Gemma-cups in *Marchantia* by High Humidity

It was noticed that gemma-cups in the New Zealand liverwort *Marchantia berteroana* L. and L. (= *M. tabularis* Nees) were not produced when the pots were covered with glass or polythene sheets. That this effect is the result of increased humidity has been confirmed by growing plants in the saturated atmosphere of a permanent-spray house, but protected from direct falling water. All experiments were carried out on sets of 60 plants, started from disks of *Marchantia* thallus 1 cm in diameter, grown in pots of sterilized garden soil. In all experiments except the second every disk had its counterparts, cut from the same thallus, in the corresponding position in each treatment so that the material under the different treatments was exactly comparable.

In one representative experiment no gemma-cups at all were produced on a unit of 60 plants during nineteen weeks' growth in a saturated atmosphere, whereas the control plants in normal air out of doors had, in the same time, produced a total of 234 gemma-cups (mean $3·9 \pm 0·98$/plant). This difference is highly significant ($P < 0·001$).

A second experiment, using twice as many plants, resulted in a total of 10 gemma-cups (mean $0·08 \pm 0·75$/plant) in saturated air compared with 1,049 cups (mean $8·74 \pm 1·18$/plant) in normal air. The difference is again highly significant ($P < 0·001$).

A similar effect was shown by a third experiment in which units covered with sheet polythene or uncovered were grown in cabinets at three different temperatures, averaging approximately 5°, 10°, and 15° C. The uncovered plants produced 2 (5° C), 9 (10° C) and 175 (15° C) gemma-cups totalling 186, while the covered plants produced no gemma-cups even at 15° C. The total production of gemma-cups was low, probably as a result of the comparatively high ambient relative humidity (about 75 per cent) in the cabinets.

Table 1 presents the results of a fourth experiment, where batches of 6 plants were transferred into the spray house after increasing periods in dry air out of doors. The equation for the regression of number of gemma-cups formed on days of dry conditions is $y = 30·8 + 1·40\ (x - 23·7)$, which is highly significant ($P < 0·001$).

Table 1. Effect of Increasing Exposure to Dry Conditions on Number of Gemma-cups formed. Counts made after 106 Days. Six Plants in Each Treatment

Days in dry conditions	1	2	4	8	16	24	32	40	48	56
Total No. of gemma-cups	1	6	0	1	11	61	36	58	56	78
No. of plants forming gemma-cups	1	1	0	1	4	5	6	6	4	6

After the end of these experiments the plants produced gametangiophores and it was possible to determine their sex, revealing that, in the material used, male plants are able to produce far more gemma-cups than are female plants. For the second experiment, the pooled comparative mean numbers of gemma-cups per plant are $60·13 \pm 7·52$ for male and $4·29 \pm 4·48$ for female plants. This difference is not due merely to the male plants being larger, since the average number of gemma-cups per unit of area of the thallus is male 0·87/cm^2 compared with female 0·07/cm^2. The sex difference also accounts for the rather low numbers of gemma-cups on the plants of the first experiment, for all these turned out to be female.

The precise humidity which is responsible for this suppression of gemma-cup formation is not yet known.

The Genus *Oceanopapaver*

The monotypic genus *Oceanopapaver* was established for the naming of *O. neocaledonicum* by Guillaumin[1]. Because of certain characters which need not be discussed here he relegated his new genus to Papaveraceae. Friedel[2] cast some doubt on this classification and suggested that the plant showed a number of characters not unlike those of the Cistaceae. Fedde[3], in a review of the Papaveraceae, expressed scepticism about allocating this new genus to that family. Among other criteria he saw some difficulty in finding a papaveraceous plant endemic to the tropical New Caledonia in the southern hemisphere.

Thanks to Prof. H. S. McKee, Commonwealth Scientific and Industrial Research Organization, Canberra, Australia I was able to make an examination of this plant for alkaloids. 400 g of dried material were available, collected when only a few of the seeds had matured. Fortunately this is the stage in most herbaceous plants when the alkaloid content is at a maximum.

The coarsely ground material was thoroughly extracted with methanol, the methanol was evaporated from the extract, the latter extracted with slightly acidified water, the aqueous extract filtered, and exhausted with repeated fresh portions of ether. (The ether extract failed to yield fumaric acid—a common constituent of papaveraceous plants.) A test portion of the aqueous extract did not give a precipitate with potassium mercuric iodide—a test which when positive is an almost certain indication of alkaloids. So far no alkaloid-bearing plants are known which give a negative test with this reagent.

Nevertheless, the aqueous solution was rendered basic with ammonia and extracted with several successive portions of chloroform. The residue from the latter was stirred with aqueous oxalic acid, the filtered solution exhausted with ether, made alkaline again, and extracted with chloroform. The residue from the latter dissolved only partly in dilute acid and the solution did not give a precipitate with the aforementioned reagent.

Inasmuch as all plants of the Papaveraceae, which have so far been examined, have yielded alkaloids, their complete absence in *O. neocaledonicum* can be regarded as sufficient cause for relegating this plant to another family.

A Glossopteridean Fructification from India

About six genera of reproductive organs have been described as belonging to the *Glossopteris*[1-3]. Some other types have also been reported from time to time[4-8]. Only a few of them occur in India[9-12]. The fossil described here came from Pachwara Coalfield, Bihar (basal Barakar—Lower Permian).

The so-called fructification is a mould-like structure on very fine greyish clayey shale. It compares favourably with the structure of the genus *Lanceolatus*[1]. The leaves associated with it cannot be determined accurately because of their bad preservation. They are simple and lanceolate in shape. Their well-developed midribs and crowded anastomosing veins clearly resemble those of some members of the *Glossopteris*.

It is assumed that the two overlapping leaves completely cover the upper half of the leaf to which the slightly raised fructification is attached (Fig. 1). The hollow nature of the midrib bearing the fructification is not clear possibly due to its poor preservation.

The fructification seems to be fully mature, lanceolate and slightly raised (14 × 7 mm). There is a deep groove along the periphery of the fructification. Immediately above the point of attachment of the fructification there is a slightly raised structure, which is perhaps the remnant of the cupular covering. It is almost sessile and grows from the midrib of the leaf; but the actual distance from the leaf-base cannot be determined due to the broken nature of the specimen. The surface shows shallow depressions of many embedded, small, more or less oval bodies (0·9 mm–1 mm), which may be the ruptured seed- (or pollen-) bearing sacs (Fig. 2).

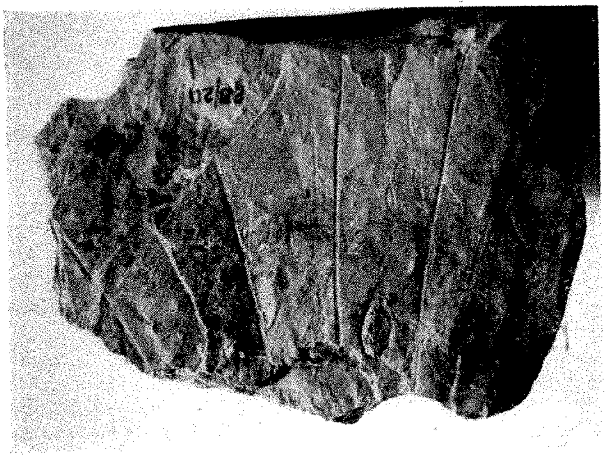

Fig. 1. *Lanceolatus* type of fructification attached to a leaf of *Glossopteris*. The head is slightly raised. Slightly reduced from natural size

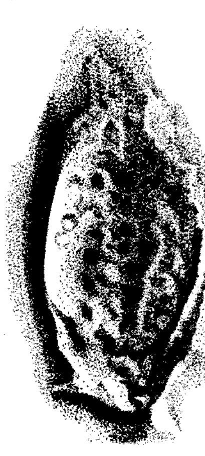

Fig. 2. Magnified view of the fructification pitted with hollow depressions which are believed to be ruptured sacs. (× 3)

It appears, therefore, that this type of fructification can only be compared with that of *Lanceolatus* type. The only other similar record from India comes from Murulidih Colliery in Jharia Coalfield, Bihar (Raniganj—Upper Permian)[11]. This shows that the genus at least occurs from the basal Barakar to Raniganj stage, that is, Lower Permian to Upper Permian of India.

A Reversal Effect with Pauses on Mixed Schedules of Reinforcement

Fixed ratio (*FR*) schedules of reinforcement typically generate behaviour that occurs with high probability just before reinforcement, but that is unlikely to be repeated for at least a little while afterwards. Also, these post-reinforcement pauses depend on the length of the ratio. Pauses are normally short when the ratio is small and are longer when a larger number of responses is required per reinforcement[1]. In the case of simple *FR* schedules it is impossible to decide whether longer pauses follow longer runs because these runs generate more reactive inhibition than do short runs[2] or because on high ratios organisms have 'a long way to go' between reinforcements[3], because run lengths before and after reinforcements are equal.

But the relative effects of pre- and post-pause response runs on pauses after reinforcements can be investigated by means of alternating mixed *FRFR* schedules of reinforcement in which reinforcements are given at the end of each ratio. The alternating ratios can be made unequal, and if pre-reinforcement run lengths alone are responsible for the duration of post-reinforcement pauses then long pauses should follow long runs and short pauses come after short ratios on the average. If pauses depend on the amount of responding required before the next reinforcement, then the reverse will be true.

Findley[4] has published observations which appear to show that pauses are a function of ratios they precede. Salman[5], on the other hand, found that a rat trained to bar press on an alternating multiple schedule *FR*40*FR*93 consistently made longer median pauses after the longer than after the shorter ratio, and the same was true, but less marked, of two other animals reinforced on *mult. FR*27*FR*73 and *mult. FR*10*FR*57 respectively. (On multiple compound schedules a different external stimulus is correlated with each segment of the schedule. This condition obtained in the Findley and Salman experiments. The present experiment utilized mixed schedules in which the external stimulus is the same for all components.) Salman's findings if compared with those of simple *FR* schedules indicate that it is the ratios they follow that have the major controlling influence over post-reinforcement pauses. However, when the schedules of the latter two animals were changed to *mult. FR*3*FR*31 the effect was reversed: median post-reinforcement pauses became

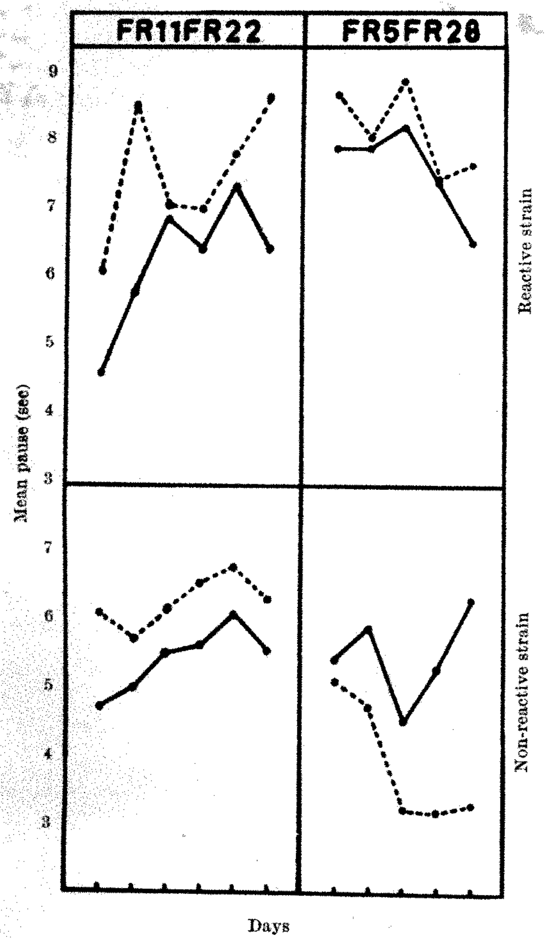

Fig. 1. Average pauses from reinforcement to the second response in the designated ratio made by reactive and non-reactive strains separately. Solid lines connect pauses after the shorter of the mixed ratios, and pauses after the longer ratios are connected by broken lines

longer after the *FR*3 component than after *FR*31. This communication presents further results on this reversal effect.

Six 5-months-old naïve male albino rats, 3 from each of the 19th generation of the Maudsley reactive and non-reactive strains, were trained to bar press for food reinforcement in a Skinner box (Scientific Prototypes type 102). The *Ss* were adapted to a 24-h feeding rhythm and were run 22–23 h food deprived daily for 30 min each, except for days 33–37 when sessions lasted 20 min. Reinforcements were scheduled as follows: days 1–3, *crf*; 4–5, *FR*4; 6–7, *FR*8; 8–16, *FR*111; 7–27, *mix FR*11*FR*22; 28–37, *mix FR*5*FR*28. The results shown in Fig. 1 were collected on days 22–27 and 33–37. These show the mean post-reinforcement pauses after each ratio of the schedules *mix FR*11*FR*22 and *mix FR*5*FR*28 for the two strains separately. The pauses were measured from reinforcement delivery to the second response in the following ratio. The second response was chosen because the non-reactive *Ss* frequently drank after reinforcement and depressed the bar once on moving from food magazine to drinking tube. The reactive *Ss*, on the other hand, typically made a one-bar response quickly after reinforcement, then bit at the bar before running off the rest of the ratio. A count over days 13–16 showed the non-reactives to average 40·9 trips to the water bottle each session against 3·8 trips by the reactives, and there were no overlaps.

Both strains consistently took slightly longer to resume bar pressing after the longer component of the *mix FR*11*FR*22 schedule. From the point of view of simple *FR* schedules, this would mean that post-reinforcement pauses are determined by the ratios they follow: longer pauses follow longer ratios. But when the schedule was changed to *mix FR*5*FR*28 the position was reversed in the case of the non-reactive *Ss*. Pauses after *FR*5 (before *FR*28) remained about the same as those after *FR*11 (before *FR*22), but the pauses after the longer ratio dropped from about 6 sec to a little more than 3 sec when the shorter ratio to follow changed from *FR*11 to *FR*5. Typical behaviour of the non-reactive *Ss* was to run off the *FR*28, pause briefly, run off the *FR*5 and then take a longer pause, showing pauses to be mainly controlled by the ratio to follow.

It is clear that post-reinforcement pauses on ratio schedules are not determined by either pre- or post-pause ratios alone, but by the relationship between them. In all probability, on small simple *FR*'s it is a fact that only a few responses after reinforcement are required before the next reinforcement that causes an animal quickly to resume responding, while on longer *FR*'s post-reinforcement pauses are more under the control of preceding runs. In any event, the Hullian notion of reactive inhibition is not sufficient to account for all the results.

MICROBIOLOGY

Molybdenum and Iron Requirements for Nitrate Reductase in *Photobacterium sepia*

Sadana and McElroy[1] showed that nitrate reductase from the halophytic bacterium, *Achromobacter fischeri*, required iron for its activity, but a deficiency of other micronutrients including molybdenum did not appear to affect the enzyme. In addition, they found that the bacterium would not grow with nitrate as the sole nitrogen source. We now report that this bacterium (kindly supplied by Dr. W. D. McElroy, Johns Hopkins University, Baltimore) has all the characters of *Photobacterium sepia* as described by Spencer[2], who suggests that it should be placed in the genus *Aeromonas*. Moreover, we present evidence that not only will this bacterium grow with nitrate as the only nitrogen supply but also that its growth and nitrate reductase activity are markedly reduced in cells deficient in molybdenum or iron. Thus the enzyme from *Photobacterium* follows the same pattern established for nitrate reductases in other micro-organisms[3–6].

The bacterium was grown in 1·5-l. Erlenmeyer flasks on a reciprocator, and 1, 10 and 20 per cent oxygen in nitrogen gas mixtures were sparged through the cultures. The following culture solutions (units/l.) were used: 30 g NaCl; 5·5 g Na_2HPO_4; 2·1 g KH_2PO_4; 0·2 g $MgSO_4.7H_2O$; 3 ml. glycerol; 2 mg iron (as $FeCl_3$) and 0·1 mg molybdenum (as $(NH_4)_6Mo_7O_{24}\cdot 4H_2O$) with either 12·2 g KNO_3 or 6·5 g NH_4Cl. The trace metals used were spectrographically checked for purity. The two micronutrients were removed from the culture medium by the hydrogen sulphide/copper co-precipitation method for molybdenum[7] and by the calcium carbonate adsorption procedure for iron[8]. All cultures were incubated at 24° C for 18 h.

The nitrate reductase activity of the cells was assayed anaerobically in Thunberg tubes using reduced benzyl viologen as the hydrogen donor. The reaction mixture was as follows: in the side-arm, 0·2 ml. 10^{-3} M benzyl viologen (BV), 1 mg palladized asbestos, and 0·3 ml. $2\cdot5 \times 10^{-1}$ M phosphate buffer (*p*H 7·5); in the tube, 0·1 ml. 10^{-1} M KNO_3, 0·1 ml. cell suspension (2 mg nitrogen/ml.) and 0·3 ml. of the phosphate buffer (*p*H 7·5). The tube was evacuated and flushed with high-purity hydrogen, which was treated in a 'Deoxo' catalytic deoxygenator. This was repeated twice, at which stage the dye was fully reduced. After final evacuation, the tubes were pre-incubated for 5 min at 30° C before the reduced dye was tipped in, and after a further 10 min the reaction was stopped by adding 0·1 ml. M zinc acetate and 1·9 ml. 95 per cent ethanol[9]. After centrifuging at 4,000*g* for 5 min, nitrite was determined in an aliquot of the supernatant solution by the sulphanilamide method[10].

Table 1. EFFECT OF OXYGEN PRESSURE, NITROGEN SOURCE AND MOLYBDENUM CONTENT OF THE CULTURE MEDIUM ON THE NITRATE REDUCTASE ACTIVITY OF CELLS

(Specific activity of the enzyme: μmoles NO_2^-/mg nitrogen/10 min)

Nitrogen source	O_2/N_2 (per cent)	Mo μg/l. culture		
		0	10	100
KNO_3	1	700	5,250	7,970
	10	250	3,930	4,360
	20	200	4,240	4,750
NH_4Cl	1	364	4,850	5,130
	10	108	840	850
	20	221	1,365	1,085

The results in Table 1 show that nitrate reductase activity was reduced by a deficiency of molybdenum, irrespective of the oxygen pressure or the source of inorganic nitrogen in the medium. An increase in the oxygen supply markedly depressed enzyme formation in agreement with the results of Pichinoty and d'Ornano[11] with *Aerobacter aerogenes*. It is of interest that the enzyme was formed in cells grown with ammonium chloride, in the absence of its substrate. This contrasts with nitrate reductases in other micro-organisms and higher plants, which are induced by nitrate or nitrite only[3-6] and are inhibited by ammonia as a result of a 'feed-back' mechanism[12].

The enzyme is also dependent on iron for its activity as shown in Fig. 1, in agreement with the results of Sadana and McElroy[1] for the same bacterium. Since the fractionation procedure used to purify nitrate reductase from extracts of cells grown with KNO_3 is also applicable to those from cells grown with ammonium chloride, it is likely that it is the same enzyme.

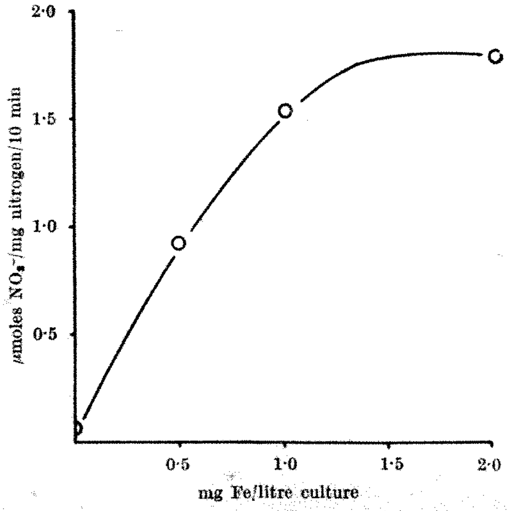

Fig. 1. Effect of the iron content of the culture medium with NH_4NO_3 (5 g/l.) as nitrogen source on the nitrate reductase activity of the cells. Cultures aerated with 10 per cent oxygen in nitrogen

Distribution of a Surface Antigen of *Staphylococcus aureus*

SEVERAL years ago the isolation of a surface antigen from culture supernatants of a mucoid strain of *Staphylococcus aureus* was reported[1,2]. The material, from strain Smith, was designated as SSA (Smith surface antigen). It consisted primarily of an amino sugar which did not behave as the usual 2-deoxy-2-amino-hexose, and which rapidly decomposed during acid hydrolysis. Later, the unknown substance was characterized as 2-deoxy-2-amino-glucuronic acid[3].

The antigen precipitated at high titre with homologous antiserum and with antiserum prepared against an *S. aureus* strain which contained serologically identical material. Other *S. aureus* antisera did not react. Injection of the isolated antigen protected mice against intraperitoneal challenge with strain Smith suspended in mucin; furthermore, the antigen was shown to be a determinant of phagocytosis of this organism.

Several other mucoid strains of *S. aureus*, as well as the Smith strain, have been reported to be more virulent for mice, and more resistant to phagocytosis than the usually occurring *S. aureus* organism[4,5]. The work reported here was designed to determine if these strains contained SSA, and also to test for the presence of SSA in strains of *S. aureus* freshly isolated from routine clinical material.

The mucoid organisms utilized, in addition to strains Smith and Stern[2], were Welwood, Adams, *K*6 and *K*93, which were kindly supplied by Dr. M. G. Koenig. Twenty-five clinical isolates were obtained from New York Hospital through the courtesy of Drs. S. Hadley and H. Shinefield.

Although SSA can be isolated from culture supernatants, it was found that acid extraction of intact bacterial cells also liberated the antigen. Cells from overnight cultures on nutrient agar in Blake bottles were collected in 10 ml. of saline adjusted to *p*H 2. The suspensions were heated at 100° C for 15 min, neutralized, and the bacterial bodies removed by centrifugation. The extracts were then tested for the presence of SSA by capillary precipitin tests using a potent Smith antiserum.

All the extracts of the six selected mucoid strains reacted within 30 min, yielding a heavy precipitate. Reactive material from these organisms was also found in fluid expressed from agar by freezing and thawing after removal of bacterial growth. Thus, the antigen, like many capsular substances, is both bound to cells and liberated into the surrounding medium. None of the acid extracts of the hospital strains precipitated with Smith antiserum, nor could specific serological material be obtained from these organisms by altering the conditions of extraction, freezing and thawing the cultures, or disrupting the cells in a Mickle disintegrator.

Material was also precipitated from acid extracts by the addition of 5 volumes of acetone, dried, taken up in saline, and tested for SSA content. As little as 100 μg/ml. of the *p*H 2 extracts from the six mucoid strains was rapidly precipitated by Smith antiserum whereas as much as 10 mg/ml. of material from the other strains was unreactive.

The specificity of the immune precipitation was examined in gel diffusion studies. Smith antiserum reacted with 1 mg/ml. solutions of the acid extracts which were positive in the precipitin test to produce a single band which in turn showed a reaction of identity with purified SSA (Fig. 1). The diffusible substances obtained by freezing and thawing the agar were also immunologically identical with SSA. There was no reaction with 10 mg/ml. of acid extracted material from the other *S. aureus* organisms. Furthermore, antisera prepared against the six selected mucoid strains reacted with SSA whereas antisera against the other strains did not.

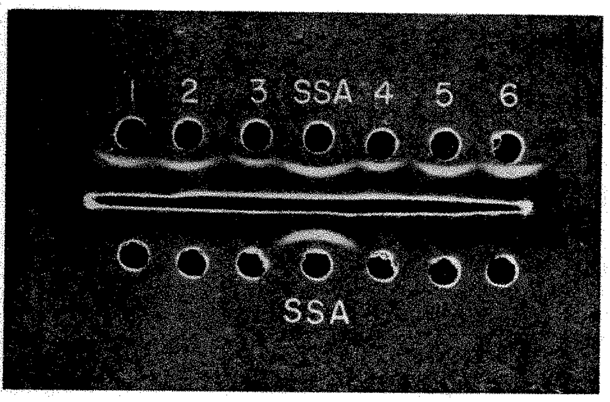

Fig. 1. Reactions of acid extracts of *S. aureus* strains with Smith antiserum. Top row: 1 mg/ml. of extracts of strains (1) *K*93, (2) *K*6, (3) Smith, (4) Stern, (5) Adams and (6) Welwood. Bottom row: 10 mg/ml. of acid extracts of other *S. aureus* strains. Concentration of SSA is 100 μg/ml.; Smith antiserum is in centre slit

The 25 strains obtained from clinical sources therefore did not contain SSA. These organisms included 7 strains in Phage Group I, 6 of which were type 80/81; 5 in Group II; 6 in Group III; and 7 which were not typable. Virtually all the strains were resistant to penicillin and isolated from active lesions. All produced both free and bound coagulase. The strains containing SSA produced free but not bound coagulase and were non-typable. It is of interest that strain Smith at one time was phage-type 44*A*/42*E*, but during the course of laboratory sub-culture it has become untypable.

It has been suggested that a determinant of pathogenicity of *S. aureus* might be capsular material such as SSA[6]. As indicated in this report, SSA was not demonstrated in routine clinical isolates of *S. aureus*; nor have other specific surface antigens been found in these organisms. It should also be noted that some of the selected strains containing SSA were obtained from normal flora rather than from active lesions[7]. In addition, two of the SSA positive strains have been carried in this laboratory for a number of years, suggesting that the antigen is not readily lost on sub-culture on artificial media.

Recently, material has been isolated from a mucoid *S. aureus* organism similar to strain Smith[8,9]. The compound bears many similarities to SSA: it is present in acid extracts of intact cells; it protects mice against intraperitoneal challenge with mucoid, but not 80/81, *S. aureus* strains; and it contains the same fundamental carbohydrate unit as SSA, aminoglucuronic acid.

This substance was described as a 'new' staphylococcal antigen and called SPA (staphylococcal protective antigen). There is no reason for believing that SPA is significantly different in chemical or immunological properties from SSA. It would be unfortunate, as well as misleading, if two identical antigens were denoted by two separate designations. Since strain Smith is the prototype of the unique mucoid *S. aureus* strains, the original designation of Smith surface antigen, or SSA, would seem to be preferable.

This investigation was supported by research grant *AI*–04648–02 from the National Institute of Allergy and Infectious Diseases, Public Health Service.

Control of Growth and Morphogenesis in some *Myxococcus* Species

THE influence of nutrition on growth and (particularly) on morphogenesis of some fruiting myxobacteria was observed in this laboratory some two years ago. As recently reported[1], a number of *Myxococcus* strains grow luxuriantly on an agar (2 per cent w/v) medium containing enzymatically hydrolysed casein (Difco 'Tryptone', 1 per cent w/v). However, only vegetative cells are present; neither the formation of microcysts (cellular morphogenesis) nor of fruiting structures (colonial morphogenesis) takes place. Microcyst and fruiting body formation does occur, however, when the 'Tryptone' concentration is reduced to 0·1 or 0·2 per cent (w/v).

It seemed possible that these morphogeneses might result from a depletion in the 'low' 'Tryptone' medium of some essential nutrient(s) which would be present in the 1 per cent 'Tryptone' medium in amounts sufficient to support continued vegetative cell growth. An experimental test of this starvation hypothesis was carried out by transferring replicate vegetative cell populations to fresh 'low' 'Tryptone' medium at intervals as short as 4 h. All such cell populations, including those control populations which were not transferred, encysted and fruited at nearly the same time. Thus, even those cell populations which were continually in a fresh 'fruiting' medium, and which had little, if any, opportunity to deplete their nutritional environment underwent morphogenesis in the normal fashion. Cell populations similarly transferred to the non-fruiting medium (1 per cent 'Tryptone') did not encyst or fruit. Very little, if any, growth or morphogenesis occurred on a non-nutrient water agar.

A number of non-encysting, non-fruiting spontaneous mutants of several myxococcal strains have been isolated. None of these could be stimulated to encyst or fruit when grown on rabbit dung pellets, or on an agar medium containing *E. coli* cells, or on 'low' 'Tryptone' medium supplemented with either killed or viable microcysts or with extracts made from wild-type cells in the process of fruiting, nor with supplements of vitamins, amino-acids, purines or pyrimidines.

In view of these failures to implicate nutritional deficiency as a regulatory factor in encystment or formation of fruiting body an alternative explanation was considered. Previous work in this laboratory had demonstrated that addition of acid-hydrolysed casein to the 'low' 'Tryptone' medium would inhibit the morphogeneses, thus suggesting that an inhibition or repression mechanism of control might be involved. An auxanographic approach used to determine if any single amino-acid, purine, pyrimidine, or vitamin could substitute for the presumed inhibitory component(s) in the acid-hydrolysed casein. Of some forty compounds tested, only phenylalanine or tryptophan inhibited the morphogeneses. Dworkin[2] has since noted that phenylalanine affects the morphogenesis of his strain of *Myxococcus xanthus* when grown on a defined medium.

It seems likely that the non-encysting, non-fruiting mutants are characterized by an increased synthesis and excretion of similarly inhibitory compounds; combined plating of mutant and wild-type cells on the 'low' 'Tryptone' medium results in inhibition of encystment and fruiting of the wild-type. With auxanographic methods it has been possible to demonstrate that some, but not all, of these mutants will fruit near the areas containing the amino-acid analogue β-2-thienylalanine, presumably because this analogue has interfered with amino-acid metabolism.

This series of observations suggests that phenylalanine and/or tryptophan are essential for both growth and morphogenesis of vegetative cells but, when present above certain concentrations, are effective in inhibiting encystment and fruiting body formation. They do not appear to inhibit microcyst germination. Their mode of action is unknown.

This work was supported in part by a U.S. Public Health Service research grant, *E*-03459.

Note added in proof. A more detailed account of Dworkin's studies have appeared (*J. Bacteriol.*, 86, 69; 1963) since this communication was submitted for publication.

ENTOMOLOGY

A Chitinase from the Gut of the Cockroach *Periplaneta americana*

CHITINOLYTIC activity has previously been demonstrated in the gut contents of *Periplaneta americana* (L.)[1], and a fraction, chitinase I, has now been separated and purified from this source by ammonium sulphate precipitation followed by fractionation on DEAE cellulose. Two additional peaks with acetylaminodeoxyglucosidase and another with chitinase activity were also observed in the effluent from DEAE cellulose columns. The terms chitinase and acetylaminodeoxyglucosidase as used here refer to enzymes No. 3/2/1/14 and No. 3/2/1/30 of the International Union of Biochemistry nomenclature[2]. Chitobiose, a substrate of chitobiase (enzyme No. 3/2/1/29), is the disaccharide of acetylaminodeoxyglucose, and the other oligosaccharides used form a series[3]. For convenience the oligosaccharides are referred to as biose, triose, etc. The chitin used was a suspension prepared by reprecipitation of purified crayfish (*Jasus verreauxi* H. M. Edw.) chitin from sulphuric acid. The products of digestion, up to hexaose, were satisfactorily separated by paper chromatography using a solvent of pentan-2-ol/pyridine/water (1:1:1)[4]. Oligosaccharide spots were located by chlorination followed by a starch-iodide spray in a modification of the Rydon and Smith[5] method for peptides. The oligosaccharides gave similar colour densities per unit weight, unlike the results given by other methods, such as silver development, in which the colour varies considerably with the size of the oligosaccharide.

Chitinase I (0·028 mg/ml.) digested 35 per cent of chitin in 5 h. The amount of digestion was determined by the change in optical density at 420 mμ (Beckman spectrophotometer, model *DU*) of a chitin suspension (2 mg/ml.) in 0·005 M citrate buffer, *p*H 4·5. The enzyme preparation was free of acetylaminodeoxyglucosidase activity using phenyl acetylaminodeoxyglucoside and chitobiose as substrates.

Reaction mixtures containing chitinase I (0·001 mg/ml.), oligosaccharides (1 μmole/ml.) and citrate buffer *p*H 4·5 (0·005 M) were incubated at 35° C for periods up to 5 h. The disappearance of the substrate spots on the chromatograms proceeded in order of increasing rate tetraose < pentaose < hexaose. The products from hexaose were biose, triose and a small amount of tetraose; from pentaose-biose and triose; and from tetraose only biose. No acetylaminodeoxyglucose was observed in these mixtures, and biose and triose were apparently not attacked by the enzyme. Under otherwise similar conditions but with increased enzyme concentration (0·028 mg/ml.) and time (18 h), biose was not affected, but about 40 per cent of triose was digested producing biose and acetylaminodeoxyglucose. This was confirmed by estimation of acetylaminodeoxyglucose[6]. The results are recorded in Table 1, in which the original amount of each substrate was assigned 6+ according to the colour of the chromatogram spot and the amount of each product was assessed similarly. Mixtures of chitin suspension or purified chitodextrin (2 mg/ml.) and chitinase I (0·028 mg/ml.) under conditions similar to the foregoing produced biose, triose, a little tetraose and a trace of acetylaminodeoxyglucose.

Table 1. DIGESTION OF CHITIN OLIGOSACCHARIDES BY CHITINASE I

Substrate	Enzyme (μg/ml.)	Time (h)	Products 1	2	3	4	5	6
Biose	28	18		6+				
Triose	28	18	1+	2+	3+			
Tetraose	1	1		1+		5+		
	1	5		3+		3+		
Pentaose	1	1		1+	2+		3+	
	1	5		3+	3+		0	
Hexaose	1	1		1+	2+	1+		2+
	1	5		2+	3+	1+		0

Reaction mixtures contained 1 μmole/ml. substrates and 0·005 M citrate buffer *p*H 4·5. Incubated at 35° for times shown. Products are labelled 1, 2, etc., in order of molecular weight of oligosaccharide, and amounts are based on colour of chromatogram spots.

Chitinase I is incapable of splitting chitobiose, splits chitotriose very slowly and higher oligosaccharides at a considerably faster rate. The production of biose and triose from hexaose shows that random splitting occurs and that chitinase I is an endoenzyme. Two chitinases from *Streptomyces*[7] acting on chitin produce considerable amounts of acetylaminodeoxyglucose and the only other product is biose, thus differing from chitinase I, which produces varying amounts of higher oligosaccharides but very little acetylaminodeoxyglucose.

The action of chitinase I resembles that of salivary α amylase[8], which produces the higher oligosaccharides but little or no glucose from starch. It appears that, because of the preference for the second or subsequent bonds in the oligosaccharides, the production of acetylaminodeoxyglucose by chitinase I is very slow, and in practice may occur only when triose remains in relatively high concentration.

VIROLOGY

Interference between Polioviruses and the Effect of Ultra-violet Light

INFECTION of animal cells with one type of poliovirus interferes with the growth of another, superinfecting, type added 30–60 min later[1,2]. On the other hand, simultaneous infection with type 1 and type 2 polioviruses can result in both types of viral RNA growing in the same cell, and in a considerable degree of phenotypic mixing in the progeny[3,4] This communication describes a case of interference between two strains of poliovirus after simultaneous infection at equal multiplicities

ERK cell monolayers were trypsinized and maintained in suspension overnight in growth medium at 36° C (ref 5) Suspended cells were infected or superinfected at 0° C (ref 5), and incubated in cell-growth medium at 36° C Samples were lysed with 0 2 per cent deoxycholate and diluted through either type 1- or type 2-specific antiserum before plaque assay[6]

In the first experiment (Table 1), cells were infected at 0° C with a mixture of type 2, *MEF*–1 (*MEF*) and either (*a*) type 1, Brunhilde (*BH*), or (*b*) type 1, Brunenders (*BE*), 5 adsorbed plaque-forming units of each type per cell After incubation for 4 h at 36° C, the progeny in flask (*a*) could be neutralized to the extent of 70 per cent by type 1 antiserum and 73 per cent by type 2 antiserum, indicating the presence of about 43 per cent of doubly neutralizable infective particles[3,4] In flask (*b*), however, the progeny were almost exclusively type 2, although a subsequent experiment demonstrates that the inoculum of type 1 (*BE*) alone was sufficient to infect all susceptible cells Separate one-step growth curves of *MEF* and *BE* were constructed under identical conditions, but no differences could be found between latent periods, rates of maturation, or final yields of the two viruses

Poliovirus which had been irradiated with ultra-violet light before adsorption to cells was not able to interfere with the growth of a later-infecting strain[1,7] In order to investigate the effect of ultra-violet irradiation on the ability of *MEF* (type 2) to interfere with the growth of simultaneously adsorbed *BE* (type 1), cells were infected (3 original plaque-forming units of each virus per cell) with a mixture of untreated *BE* and irradiated *MEF* (7 per cent survival of plaque-forming units) After incubation for 5 h at 36° C, the progeny were predominantly type 1 (Table 1, Exp 2), thus irradiation of *MEF* had much reduced its capacity to interfere with simultaneous *BE* The total yield of plaque-forming units was no less than in a control culture infected with the same two viruses without irradiation, confirming that the inoculum of *BE* was sufficient to infect all the cells In a further experiment it was found that in cells infected with *MEF*, incubated for 30 min at 36° C and then irradiated (sufficient to reduce the 5-h yield of *MEF* to 8 per cent of normal), the yield of superinfecting *BE*, added immediately after irradiation, was only 10 per cent of that in control cells infected with *BE* alone after similar irradiation (Table 1, Exp 3)

Table 1

Exp No	Treatment* of cells/time of infection or ultra-violet irradiation	Time of lysis (h)	Total yield plaque-forming units/cell	Percentage of infectivity neutralized by antiserum Type 1	Type 2
1	(*BH* + *MEF*)/0 h	4	40	70	73
	(*BE* + *MEF*)/0 h	4	38	10	92
2	(*BE* + *MEF*)/0 h	5	160	15	92
	(*BE* + U-V'd *MEF*)/0 h	5	160	94	23
3	*MEF*/0 h	4 5	52	0	90
	MEF/0 h, U-V/0 5 h	4 5	4 0	0	90
	MEF/0 h, U-V/0 5 h, *BE*/0 5 h	4 5	5 6	25	76
	— U-V/0 5 h, *BE*/0 5 h	4 5	14	99	0

* *BH*, infection with type 1, Brunhilde, *BE*, infection with type 1, Brunenders, *MEF*, infection with type 2, *MEF*-1

The fate of the (non-infective) RNA of ultra-violet-irradiated virus in susceptible cells is uncertain Unpublished experiments with poliovirus labelled with phosphorus-32 have shown that irradiated virus still adsorbs to cells, and that there is no gross change in the sedimentation rate of its RNA But there is no evidence that it achieves any of the early results of normal virus infection. irradiated virus, for example, does not cause an early inhibition of cellular RNA synthesis[8] as does normal virus[8–11].

However, as described here, irradiation of infected cells 30 min after adsorption of an interfering virus did not eliminate the interference, although it stopped the growth of the interfering virus It may be that irradiation of virus so alters the configuration of its RNA as to prevent its attachment to a specific site within the cell, but that RNA from infective virus once attached to the site cannot be dislodged by ultra-violet light Two strains of virus infecting simultaneously would compete with each other if they required the same or overlapping sites

An alternative possibility is that an early virus-induced protein is responsible for the interference Experiments with puromycin have suggested that protein synthesis is essential in the very early stages of infection[8,12,13] Perhaps the same early protein causes inhibition of cellular RNA synthesis and interference with superinfecting virus It would be interesting to know whether puromycin prevents this type of interference which is established within 30 min or less Interference between simultaneously adsorbed viruses (*MEF* and *BE*) by such a mechanism would infer that one (*MEF*) produced its interfering protein before the other, although this was not reflected in a measurably shorter latent period after single infection

PSYCHOLOGY

Relative Retention in Immediate Memory determined by the Missing Scan Method

STORAGE in immediate memory is often evaluated through retrieval, by requiring subjects to recall or recognize previously presented material The serial error curve generated by retrieval, which shows the distribution of errors of omission in retrieval according to the serial position of presented material, appears to reflect characteristics of retrieval as well as of storage

Some effects of retrieval on the serial error curve have been summarized by Broadbent[1] in his discussion of order effects in recall When subjects are asked to recall material in the order presented, the usual finding is that most errors occur in the second half of the series presented However, Kay and Poulton[2] found that when subjects were asked to report the second half of the list first, an equal number of errors occurred in both halves of the list Investigations by Brown[3], by Lawrence and LaBerge[4], and by Broadbent[1] have shown that items recalled first are more likely to be correct Because the first items recorded were most likely to be correct even if subjects knew in advance which to record first, Broadbent concluded that items are not recalled first because they are correct but are correct because they are recalled first Such order effects appear whenever a subject retrieves information in some order

These considerations indicate certain limitations of retrieval methods for the investigations of storage in short-term memory These limitations may be overcome by the use of sampling methods which require only partial retrieval, as Sperling[5], Averbach[6], and Coriell[7] have shown This report presents the serial error curve generated by another method which may have certain advantages for the investigation of short-term retention

The missing scan' method for the examination of retention in immediate memory[8] does not require retrieval by recall or recognition It depends on knowledge of class membership, requiring the subject to report only that member of the class which was not presented For example, nine numbers randomly chosen from the class 1–10 inclusive may be presented serially in random order the task being to report which of the 10 numbers was not presented To report the missing item correctly, all information presented must be retained, therefore the missing scan offers a sensitive measure of storage capacity If an error is committed it takes the form of reporting as missing some item that was presented, indicating relatively poorer retention of an item presented in that particular serial position The serial error curve generated by the missing scan in this way may more clearly delineate retention, uninfluenced by any recall order effects

It has been shown that most missing scan errors are in the first half of the list[8] The present experiment examines the missing scan serial error curve in detail to show relative retention in short-term storage The twenty male subjects were patients on the Neurology Service of the Palo Alto Veterans Hospital, without clinically demonstrable mental deficit, who ranged in age from 26 to 71 with a mean of 44 1 years Subjects were tested individually and instructed to report that number missing from a known set of thirteen after the examiner had read the other twelve at the rate of one each second The missing numbers were chosen at random so that each of the thirteen was equally often missing, and the remaining twelve numbers were presented in random order The sets of thirteen numbers used were 1–13 and 4–16 inclusive, all lists from one set were read before proceeding to the other Each subject received 156 such twelve-item lists in counterbalanced order

The proportion of correct reports given by all subjects clearly exceeded chance, ranging from 20 to 50 per cent with a mean of 33 per cent correct responses The missing scan error curve given here is based on the serial distribution of the 2,091 errors committed by these twenty subjects Fig 1 shows the 95+ per cent joint confidence intervals on error probabilities for each of the twelve serial positions Given the occurrence of an error, Fig 1 indicates the relative probability of 'forgetting' an item as a function of its position in a serially presented list The cross bars show in decimal form the proportion of total errors in each serial position, from which the probabilities are derived

These results confirm that most missing scan errors are found in the first half of the list, and extend independent analysis of relative retention in short-term storage to show, at the 95+ per cent level of confidence, that (1) the first item is better retained than the second, the probability of error in serial position 1 being less than that in serial position 2, (2) separate consideration of serial positions 4–12 inclusive shows a generally decreasing probability of error from position 4–12, since the probability of error in position 4 > 5, 6 > 7, 8 > 9, 10, 11 > 12

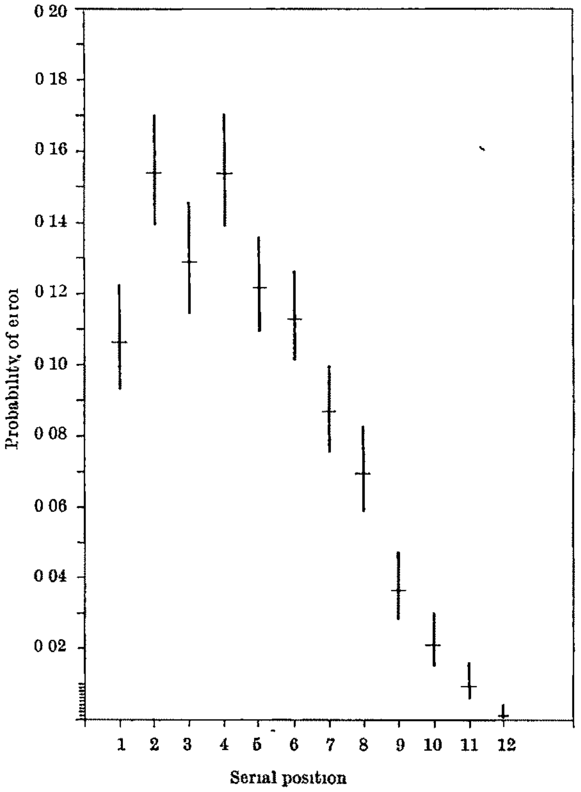

Fig 1 95+ per cent joint confidence intervals on error probabilities with respect to serial position, given that an error is committed The cross bars show in decimal form the proportion of 2,091 errors in each serial position

This missing scan serial error curve deserves further investigation because it would appear to offer more adequate independent characterization of short-term storage, for the following reasons (1) Since the missing scan does not require retrieval by recall or recognition, the serial error curve generated by this method is not influenced by any retrieval order effects (2) The missing scan offers a stronger determination of retention because the missing scan error is an error of commission while the comparable recall or recognition error is an error of omission (3) The missing scan may specifically estimate relative retention, since, in the case where there is only one missing item to be reported, the forced choice of a single item should select that item least well retained The independent analysis of storage thus available should enhance understanding of both retention in and retrieval from immediate memory

I thank Dr Helena Chmura Kraemer, research associate in the Department of Biostatistics of Stanford University School of Medicine, for the statistical analysis

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, December 16

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W C 2), at 5 30 p m —Mr W F Gibbons "Ceramic Sealing Techniques Applied to Electron Tubes and Semiconductor Devices"

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S W 1), at 5 30 p m —Mr A Stevenson "Analysis of Dithiocarbamates and Thiuram Disulphides Used in Agriculture A Collaborative Study of Macro-Methods Available for the Evaluation of Technical and Formulated Products"

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W C 2), at 6 30 p m —Sir Albert Mumford, K B E "Communications and Radio"

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 8 15 p m —Dr L S B Leakey "Exploring Man's Prehistory in East Africa"

Monday, December 16—Tuesday, December 17

British Biophysical Society (at the Institution of Electrical Engineers, Savoy Place, London, W C 2)—Symposium on "Control Mechanisms"

Monday, December 16—Wednesday, December 18

Institute of Physics and Physical Society, Electronics, Electron Microscopy and Analysis, and Low Temperature Groups (at Imperial College, London, S W 7)—Conference on "The Electrical and Magnetic Properties of Thin Films in Relation to Their Structure"

Tuesday, December 17

Institution of Civil Engineers (at Great George Street, Westminster, London, S W 1), at 5 30 p m —Mr E C Hall and Mr D R Russell "The Malta Underground Oil Fuel Installation"

Institution of Electrical Engineers, Science and General Division (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Teaching of Electrical Measurements Abolition or Reform"

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m — Dr A J Buller "Mammalian Fast and Slow Skeletal Muscle" (Last of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

Wednesday, December 18

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 15 p m —Dr F R Oliver "Inter-Regional Migration and Unemployment, 1951–1961"

Institution of Electrical Engineers, Power Division (at Savoy Place, London, W C 2), at 5 30 p m —Mr S J Emerson, O B E "Protective Earthing of Consumers' Installations"

Institution of Mechanical Engineers, Lubrication and Wear Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m — Discussion on "The Role of Metals in Lubrication"

Thursday, December 19

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 p m —Dr W Domzalski "Some Trends in Mineral Resources Exploration", followed by a film—"The West Wits Line" introduced by Mr A R O Williams

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W 1), at 5 p m —Dr B J Birch "Elliptic Curves"

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S W 1), at 6 p m —Sir William Glanville, C B , C B E "Materials and Construction Problems Bearing on Road Safety"

Friday, December 20

Institute of Navigation (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S W 1), at 5 30 p m —Mr J Bentkowsky "Bridge Console Designs"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Senior Library Assistant (with appropriate professional qualifications and/or experience), for cataloguing duties—The Librarian, University of Essex, Wivenhoe Park, Colchester, Essex (December 19)

Assistant Librarian (Chartered Librarian preferably with a university degree), for duties which will include classification and cataloguing and some help with reference and information work—Clerk to the Governors, Woolwich Polytechnic, London, S E 18 (December 20)

Assistant (preferably graduate, with a wide interest in books and reading, some experience in publishing and/or the editorial side of journalism) in the Reviews Section of the Science Department, for the selection and distribution of books and other publications (mostly scientific) to overseas reviewers—The Director, Recruitment Department, The British Council, 65 Davies Street, London, W 1, quoting Ref A9/64/G/1 (December 20)

Lecturer in Bacteriology (Science)—The Secretary of University Court, The University Glasgow (December 23)

Lecturers (2) in Pure Mathematics—The Registrar, The University, Manchester 13 (December 28)

Lecturers (3) (with research or industrial experience in electronic applications and circuit techniques, in automatic control or in engineering systems) in the Department of Electrical Engineering—The Registrar Queen Mary College (University of London), Mile End Road, London, E 1 (December 30)

Fellow and Tutor in Engineering Science—The Rector, Lincoln College, Oxford (December 31)

Imperial Chemical Industries Research Fellows—The Secretary, The University, Aberdeen (December 31)

Lecturer in Clinical Science within the Department of Surgery —The Secretary, The Queen's University, Belfast, Northern Ireland (December 31)

Lecturer (Physicist or Physical Chemist) in the Department of Physics, to assist with the teaching of the new degree course in the physical properties of materials—The Registrar (Room 22, O R B), The University, Reading (December 31)

Lecturers (2) (preferably with a special interest in the study of synthetic high polymers or in the application of radioactive tracer techniques) in Physical Chemistry—The Assistant Registrar (Science), The University, Birmingham 15 (December 31)

Unilever Research Scholar (with a first- or upper second-class honours degree in a relevant subject or able to provide evidence of research aptitude and experience) in the Department of Biological Chemistry, to assist in work on the chemistry, biochemistry or cytology of mammalian intestine —Dr J W Porteous, Department of Biological Chemistry, Marischal College, University of Aberdeen, Aberdeen (December 31)

Junior Lecturer (preferably interested in the cytological or physiological aspects of vertebrate reproduction) in Zoology—The Secretary, The Medical College of St Bartholomew's Hospital, West Smithfield London, E C 1 (January 4)

Lecturer in Geography—The Secretary of Faculties, University Registry, Oxford (January 6)

Lecturer in Chemistry at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 10)

Senior Lecturer/Lecturer in the Psychology of Education, University of Cape Town—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1, and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (January 10)

Senior Tutor-Demonstrator (with a university degree in pharmacy (or its equivalent) and teaching experience since graduation) in Pharmaceutics at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 10)

Professor of Soil Science—The Registrar (Room 22, O R B), The University, Reading (January 11)

Chair of Virology at St Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W C 1 (January 13)

Lecturer or Assistant Lecturer in the Department of Pure Mathematics—The Registrar, University College of North Wales, Bangor, North Wales (January 13)

Professor of Mathematics at Newcastle University College, The University of New South Wales—The Agent General for New South Wales, 56–57 Strand, London, W C 2, and The Appointments Section The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (London and Australia, January 13)

Professor of Physics at Newcastle University College, University of New South Wales—The Agent General for New South Wales, 56–57 Strand, London, W C 2, and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (January 13)

Lecturer or Assistant Lecturer in Physics at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 15)

Lecturers (2) in Psychology at the University of Sydney, Australia —The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 15)

Lecturer in Histology and Embryology, and a Senior Tutor/Demonstrator in Histology and Embryology at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 16)

Lecturer (with an honours degree in physics and some teaching and/or research experience) in Physics at the University of Queensland, Australia —The Secretary, Association of Commonwealth Universities (Branch Office) Marlborough House, Pall Mall, London, S W 1 (London and Brisbane, January 17)

Senior Lecturer and a Lecturer (with an honours degree in mathematics, and preferably a higher degree and some experience of research) in Mathematics at the University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (London and Brisbane, January 17)

Senior Lecturer (with a higher degree in biochemistry and considerable teaching and/or research experience in this field) in Biochemistry at the University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (London and Brisbane, January 17)

Chair of Biology (in the field of animal biology) at the University of Sydney—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 31)

Chair of Mathematics—The Secretary, University of Lancaster, Bailrigg House, Lancaster (January 31)

Lecturer in Educational Psychology—The Registrar, The University, Manchester 13 (January 31)

Second Chair in Applied Psychology at the University of New South Wales, The Agent General for New South Wales, 56–57 Strand, London, W C 2, and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (January 31)

Senior Lecturer (preferably with medical qualifications) in Pharmacology at the University of Hong Kong—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Hong Kong and London, January 31)

Foundation Chair of Mathematics (either Pure or Applied) at Wollongong University College—The Agent-General for New South Wales, 56–57 Strand, London W C 2, and The Appointments Section, The University of New South Wales Box 1, Post Office, Kensington, New South Wales, Australia (February 28)

Professor (with high academic qualifications in chemical engineering or related fields, considerable research experience, and preferably industrial experience in the fields of petroleum refining and/or petrochemicals) of

CHEMICAL ENGINEERING at the University of New South Wales—The Agent General for New South Wales, 56–57 Strand, London, W C 2, and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (March 31)

BIOLOGIST (aged 24–35, with an honours degree in zoology with post-graduate experience in animal ecology) with the Government of Tanganyika, to carry out investigations connected with the management of wild life and to advise the Chief Game Warden—The Director of Recruitment, Department of Technical Co-operation, Eland House, Stag Place, London, S W 1, quoting Ref RC 346/145/03/T

MASTER TO TEACH MATHEMATICS, including Sixth Form work—The Headmaster, Bolton School, Bolton, Lancashire

RESEARCH ASSISTANT (graduate in zoology, physiology or biochemistry), to work under the Professor of Zoology on the physiology of coelenterates and/or the water and ionic balance of invertebrates using radioactive isotopes—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W 8

RESEARCH ASSISTANT IN THE DEPARTMENT OF EDUCATION—Department of Education, The University, Old Aberdeen

TECHNICIAN FOR THE ZOOLOGY DEPARTMENT—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey

Pedigree

The "Mistral 6L" is developed from the MSE "Major Refrigerator" Centrifuge—famous throughout the world for its dependability and performance.

The New MSE "MISTRAL 6L" General Purpose Refrigerator Centrifuge

The MSE "MISTRAL 6L" represents an outstanding advance in design and performance of large capacity refrigerator centrifuges. It incorporates the following new features of great practical importance to the user:

- 4x1250 ml and 6x1000 ml Swing-out Heads up to 2,500 r p m.
- Wide range of other Swing-out and Angle Heads for large numbers of smaller bottles and tubes at high speeds.
- Exceptionally fast acceleration to top speeds.
- Electronic speed pre-selection and control
- New type of drive mounting giving vibration-free running, even with some imbalance.
- Compact and space saving—33″ (84 cm) wide, 33″ (84 cm) front to back.
- Stainless steel bowl and working-top lid.

For full details please write to:

APPOINTMENTS VACANT

PLANT PROTECTION LTD

part of

THE GENERAL CHEMICALS DIVISION OF I C I

requires staff for the following senior appointments

Serials 1, 2, and 4 will be located at Jealott's Hill, nr Bracknell, Berkshire

Serial 3 will be located at Yalding Works, nr Maidstone, Kent

Serial 5 will be located at the Company's Headquarters at Fernhurst, Haslemere, Surrey

RESEARCH CHEMISTS

Serial

1 ANALYTICAL CHEMIST or BIOCHEMIST to study the metabolism and mode of action of physiologically active substances and to develop physical methods of analysis Candidates should have a good honours degree and preferably postgraduate experience in organic or analytical chemistry

2 ORGANIC CHEMISTS with research experience and good honours degrees to work on the synthesis and the fundamental physical organic chemistry of novel pesticides They should be interested in the study of relationship between chemical structure and biological activity or in the elucidation of the mechanism and kinetics of chemical reactions

3 FORMULATION CHEMIST with industrial experience to work on problems connected with the formulation of pest control chemicals This man must have the ability to convert his findings into manufacturing practices for large-scale production An honours graduate in either chemistry or pharmacy would have a suitable academic background for this job

RESEARCH BIOLOGIST

4 BOTANIST with research experience, good honours degree, a thorough knowledge of plant physiology, and preferably some knowledge of plant pathology and mycology He will work on projects aimed at the discovery and development of new fungicides

DEVELOPMENT AND TECHNICAL SERVICE BIOLOGISTS

5 An ENTOMOLOGIST and a BOTANIST who should have good honours degrees and preferably postgraduate research experience The department is involved in the development of new products as well as in technical service for the existing range The work necessitates close collaboration with the Research Department, but will involve laying down and assessing independent trials, both at home and overseas

Written applications should be addressed to the Staff Officer, Plant Protection Limited, Fernhurst, Haslemere, Surrey, and need give brief details only

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF CHEMISTRY

Applications are invited for two Lectureships in Physical Chemistry in the Department of Chemistry Preference may be given to applicants with a special interest in the study of synthetic high polymers or in the application of radioactive tracer techniques Initial salary in the scale £1,250 by £60 to £1,670 by £80 to £1,830 , £1,830 by £80 to £2,150, according to age, qualifications and experience, together with F S S U and family allowance benefits

Applications (three copies), naming three referees, should be sent by December 31, 1963, to the Assistant Registrar (Science), the University, Birmingham 15, from whom further particulars can be obtained

AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF SOILS

PLANT PHYSIOLOGIST OR MICROBIOLOGIST

Applications are invited for appointment to a position of Research Officer (Plant Physiologist or Microbiologist) with the Organization's Division of Soils, located in Adelaide, S A

The Division of Soils is concerned with research on soils, including pedological, chemical, physical, microbiological, and mineralogical studies, together with the integration of these in investigations of soil fertility and the relationship between plant growth and soil environment

The Microbiology Section of the Division is well equipped to undertake studies in soil microbiology, biochemistry, organic chemistry, and plant physiology Equipment includes normal microbiology and biochemical requirements and in addition fluorescence microscope recording oxygen analyser, gas chromatograph infra-red and ultra-violet recording spectrophotometers, mass spectrometer, radioactive isotope counting equipment and glasshouse The Section is currently engaged on the oxidation of sulphur in soil, mycorrhizal associations on pine trees, phytotoxic substances from soil and from decomposing plant residues, microbiological prospecting for oil, microbiology of the rhizosphere, bacterial inoculation of crops, and the chemistry of soil organic matter

The successful applicant will investigate the chemical nature of plant root exudates, mechanisms of exudation under different environmental conditions, and the importance of exudates in the nutrition of micro-organisms in the rhizosphere

Applicants should possess a Ph D degree in plant physiology, biochemistry, or microbiology, or should have had postgraduate research experience of equivalent standard and duration supported by satisfactory evidence of research ability

Salary Dependent upon qualifications and experience within the range £A1,674 to £A2,511 per annum (but not less than £A1,979 per annum)

Salary for women will be £A188 per annum less than corresponding rates for men

Promotion within C S I R O is by merit and may go beyond the upper limit of the scale within which the original appointment is made

Fares paid for the appointee and his dependent family Further particulars supplied on application to Mr W Hartley Chief Scientific Liaison Officer, Australian Scientific Liaison Office Africa House, Kingsway, London, W C 2, to whom applications (quoting Appointment No 270/254) should be addressed by January 11, 1964

THE AUSTRALIAN NATIONAL UNIVERSITY

HEAD TECHNICIAN FOR DEPARTMENT OF GENETICS

Applications are invited for the position of Head Technician in the Department of Genetics, The John Curtin School of Medical Research, Australian National University, Canberra A C T The successful applicant will be responsible to the head of the Department and his duties will include supervision of technical staff, ordering of chemicals and apparatus, general administrative duties and laboratory service The Department is concerned only with research A wide experience of bacteriological and biochemical laboratory practice is required, and experience in the handling of laboratory animals would be an advantage The salary offered will be within the range £A1,884 to £A2,324 per annum The University will pay reasonable removal expenses and will provide assistance in obtaining housing for an appointment from outside Canberra The position carries superannuation long service leave and normal fringe benefits

Applications should be forwarded to the undersigned at Box 4, G P O , Canberra, A C T , Australia by December 20, 1963

W S HAMILTON,
Bursar

UNIVERSITY OF MANCHESTER

Applications are invited for two posts of Lecturer in Pure Mathematics in the Department of Mathematics in the Faculty of Science Salary scale £1,250 to £2,150 per annum, initial salary according to qualifications and experience Membership of the F S S U and children's allowance scheme

Applications should be sent not later than December 28, 1963, to the Registrar, The University, Manchester, 13, from whom further particulars and forms of application may be obtained

UNIVERSITY COLLEGE

GALWAY, IRELAND

PROFESSORSHIP OF PHYSIOLOGY

Applications are invited for the above Professorship The latest day for receiving applications will be February 20, 1964

Further information may be had from the Secretary of the College

BAKELITE LIMITED

one of the Bakelite Xylonite Limited group of companies, have a vacancy in the LIBRARY of their Research and Development Department, Birmingham, for a CHEMIST (male or female) with an Honours degree or A R I C , who would when necessary deputize for their Librarian The position offers good prospects, and candidates must have a genuine interest in the literature of pure and applied science, a logical mind for its classification and retrieval and the ability to co-operate with other members of the technical sales staff

Starting salary will be in accordance with age, qualifications, and experience There is a pension and life assurance scheme and a five-day working week

Applications should be sent to

Research and Development Manager,
Bakelite Limited,
Redfern Road, Birmingham, 11

UNIVERSITY OF GLASGOW

LECTURESHIP IN BACTERIOLOGY (SCIENCE)

Applications are invited for a Lectureship in Bacteriology (Science) Salary scale £1,250 to £2,150 per annum Initial salary according to experience and qualifications F S S U and family allowance benefits

Applications (eight copies) should be lodged, not later than December 23, 1963, with the undersigned, from whom further particulars may be obtained

ROBT T HUTCHESON,
Secretary of the University Court

APPLICATIONS ARE INVITED FROM Physicists with Ph D for a position in the Department of Physics, at the University of Victoria Victoria, British Columbia, Canada Duties, which will include teaching and research, will commence on September 1, 1964 Salary will depend upon qualifications and experience Salary floors at present are $12,000 for Professor $9,000 for Associate Professor, and $7,000 for Assistant Professor —Applications and inquiries should be addressed to the Head of the Department of Physics

Return to Research in Britain

Are you a British scientist in the U.S.A. thinking of returning to work in Britain? You may find what you are looking for, without having to go home first, in the Civil Service, the United Kingdom Atomic Energy Authority, or the Central Electricity Generating Board.

Research Fellowships and Permanent Appointments
There are openings in all branches of science. The order in which they are most numerous is (i) physics, mathematics, engineering, and metallurgy; (ii) chemistry and biochemistry; (iii) biology. The research ranges from the most fundamental to the most applied.

Assistance with fares to the United Kingdom will be considered.

A selection board of scientists will be coming to Washington, New York and San Francisco from March to May, 1964. If you would like an appointment with them, would you write by 31st January, 1964, to: Dr. J. A. Saxton, Director, United Kingdom Scientific Mission, British Embassy, Washington, D.C.

Issued jointly by the Civil Service Commission,
the U.K. Atomic Energy Authority, and the Central Electricity Generating Board

Scientific Civil Service

MATHEMATICIANS IN GOVERNMENT SERVICE

The following are examples of existing vacancies which may be filled at SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER level.

NATIONAL PHYSICAL LABORATORY, Teddington, Middlesex.
Mathematician or physicist for the development and application of methods of NUMERICAL ANALYSIS, research on problems of applied mathematics, physics and engineering, or research on problems of the solid state, liquid state, polymer physics, etc.; in each case with the APPLICATION OF HIGH SPEED COMPUTERS particularly in mind.

ROYAL AIRCRAFT ESTABLISHMENT, Farnborough, Hants.
Mathematicians for theoretical and operational studies of AIR TRAFFIC FLOW and control systems; using mathematical models, digital simulation, statistical and operational research techniques.

PROOF AND EXPERIMENTAL ESTABLISHMENT, Shoeburyness, Essex.
For theoretical and experimental investigation of the ACCURACY AND RELIABILITY of proposed and existing instrumentation systems, including data processing.

POST OFFICE RESEARCH STATION, Dollis Hill, London.
Mathematician to assist Engineers and Physicists in STATISTICAL AND NUMERICAL METHODS and programming of scientific calculations; access to electronic computers.

ADMIRALTY SURFACE WEAPONS ESTABLISHMENT, Portsdown, Hants.
Mathematician for ADVANCED COMPUTER PROGRAMMING investigation for radio/radar weapons systems.
There are many other vacancies in most scientific disciplines. Recruitment by the Civil Service Commissioners is to permanent and pensionable posts.

APPLICATION FORMS from Civil Service Commission, 23 Savile Row, London, W.1, stating age and qualifications.

MINISTRY OF AVIATION

ELECTRICAL INSPECTION DIRECTORATE, Bromley, Kent.

SENIOR SCIENTIFIC OFFICER to start and lead a small Statistical Advisory Section to advise and assist in the collection, analysis and interpretation of numerical data in connection with inspection, testing and reliability assessment. The applicant appointed will also arrange and give courses on statistical quality control methods to Inspectorate staff. Some years' experience in the application of statistical theory, preferably in statistical quality control methods necessary. Knowledge of electrical engineering an advantage.

APPLICATION FORM from Ministry of Aviation, Est. 2/3.A.3, Room 516, Adelphi, John Adam St., London, W.C.2.

WAR DEPARTMENT

ROYAL MILITARY COLLEGE OF SCIENCE, Shrivenham, Wilts.

LECTURING APPOINTMENTS in Mechanical Engineering, Chemistry and Physics for teaching at University level and lecturing to degree and specialized courses and to assist with laboratory classes. Research is encouraged and work would be suitable for publication and submission for higher degree. Extensive well-equipped laboratories.

QUALIFICATIONS: First- or second-class honours degree or equivalent qualification in appropriate subject; membership of professional body an advantage. For the chemistry post, radiochemical experience is desirable, but not essential. SALARY on scale £1,438 to £1,772 (Senior Lecturer) or £791 to £1,309 (Lecturer) according to age, experience, etc. F.S.S.U. Prospects of permanency and promotion for the posts in Mechanical Engineering and Chemistry. Accommodation provided for single man; prospects of house for married man. Further particulars and forms from the Registrar at the above address.

ROYAL NAVAL SCIENTIFIC SERVICE

GOVERNMENT COMMUNICATIONS HEADQUARTERS, Cheltenham, Glos.

SCIENTIFIC OFFICERS/SENIOR SCIENTIFIC OFFICERS:
MATHEMATICIANS required for computer application and programming, and for combinatorial and statistical research.
PHYSICISTS and ELECTRONIC ENGINEERS for research, development and design work in telecommunications field involving use of latest equipments and modern techniques.

EXPERIMENTAL OFFICERS/ASSISTANT EXPERIMENTAL OFFICERS:
MATHEMATICIANS for computer programming.

APPLY to S.S.P., Admiralty, Empress State Building, London, S.W.6.

SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

SALARIES: S.O. £791–£1309
(Increments and special £95 award for approved post-grad. experience).
S.S.O. £1438–£1772
(Starting salary may be above minimum).
Salaries are supplemented in the London Area.

QUALIFICATIONS:

S.O.: 1st or 2nd Class Hons. Degree or Dip.Tech. in appropriate subject. Age under 29.
S.S.O.: As above plus at least 3 years post-graduate research. Age 26 to 31.

ASST. EXPERIMENTAL OFFICER/EXPERIMENTAL OFFICER

SALARIES: A.E.O. £490 (age 18) – £691 (age 22) – £858 (age 26) – £1053.
E.O. £1164–£1431.
Salaries are supplemented in the London Area.

QUALIFICATIONS:

Degree, Dip.Tech., H.N.C. or equivalent in appropriate subject. Under age 22, minimum qualification is 2 G.C.E. 'A' levels in Scientific subjects. A.E.O.: age 18–27. E.O. 26–30.

Full details of careers in the SCIENTIFIC CIVIL SERVICE are available on request from Civil Service Commission, 23 Savile Row, W.1.

AUSTRALIA

THE UNIVERSITY OF NEW SOUTH WALES

invites applications for appointment to the position of

PROFESSOR OF INDUSTRIAL ENGINEERING

SCHOOL OF MECHANICAL ENGINEERING

Salary will be £A4,605 per annum. The Professor will take charge of the Department of Industrial Engineering within the School of Mechanical Engineering. The Department offers both undergraduate courses (B.E., B.Sc.(Tech.)) and postgraduate courses (postgraduate diploma, M.Tech.) as well as providing facilities for research leading to higher degrees. Applicants must have extensive industrial experience as well as high academic qualifications and research ability. Subject to the consent of the University Council, Professors may undertake a limited amount of higher consultative work. The University reserves the right to fill the position by invitation.

Details of conditions of appointment, including superannuation, travel arrangements, study leave, housing scheme, may be obtained from the Agent-General for New South Wales, 56-57 Strand, London, W.C.2. Four copies of applications should be typed and forwarded, together with the names of three referees and a recent photograph, to the Agent-General before February 17, 1964. A copy of the application should be forwarded by airmail to the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N.S.W., to reach there before the above-mentioned date.

AUSTRALIA

THE UNIVERSITY OF NEW SOUTH WALES
SYDNEY

SENIOR LECTURER/LECTURER
in
INDUSTRIAL CHEMISTRY
NEWCASTLE UNIVERSITY COLLEGE

Salary: Senior Lecturer, £A2,755 range £A3,255 per annum. Lecturer, £A1,905 range £A2,605 per annum. Commencing salary according to qualifications and experience. Applicants must hold an honours degree in science, applied science or chemical engineering or have equivalent qualifications. For appointment as Senior Lecturer a higher degree is essential. Teaching or research and industrial experience would be advantageous. The successful applicant, if a Senior Lecturer, will be responsible to the Head of the Department of Chemical Engineering and Industrial Chemistry for undergraduate instruction in industrial chemistry to the fourth year honours level and for the supervision of postgraduate research in the same subject.

Details of conditions of appointment may be obtained from the Agent-General for New South Wales, 56-57 Strand, London, W.C.2, with whom four copies of applications and names of two referees, should be lodged before February 17, 1964, and a copy of the application forwarded by airmail to the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, to reach there before the above-mentioned date.

AUSTRALIA

THE UNIVERSITY OF NEW SOUTH WALES
SYDNEY

invites applications for appointment to the
FOUNDATION CHAIR OF MATHEMATICS
(either Pure or Applied)
WOLLONGONG UNIVERSITY COLLEGE
(An associated College of the University of New South Wales)

Salary will be £A4,605 per annum. Candidates should have strong research interests in one or more branches of mathematics. The courses offered at the Wollongong University College lead to the degrees of the University of New South Wales and, within the framework, the Professor will be expected to develop at the College undergraduate and graduate studies in mathematics. The College was established in 1961 and is situated in the most rapidly expanding city in Australia. Wollongong is fifty miles from Sydney and there is ready access to adjacent universities and research establishments. The College is expanding and in 1964 will commence offering courses in Arts and Commerce. Subject to the consent of the University Council, Professors may undertake a limited amount of higher consultative work.

Details of conditions of appointment may be obtained from the Agent-General for New South Wales, 56-57 Strand, London, W.C.2. Four copies of applications should be typed and forwarded, together with a recent photograph and the names of three referees, to the Agent-General before February 28, 1964, and a copy forwarded by airmail to the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales.

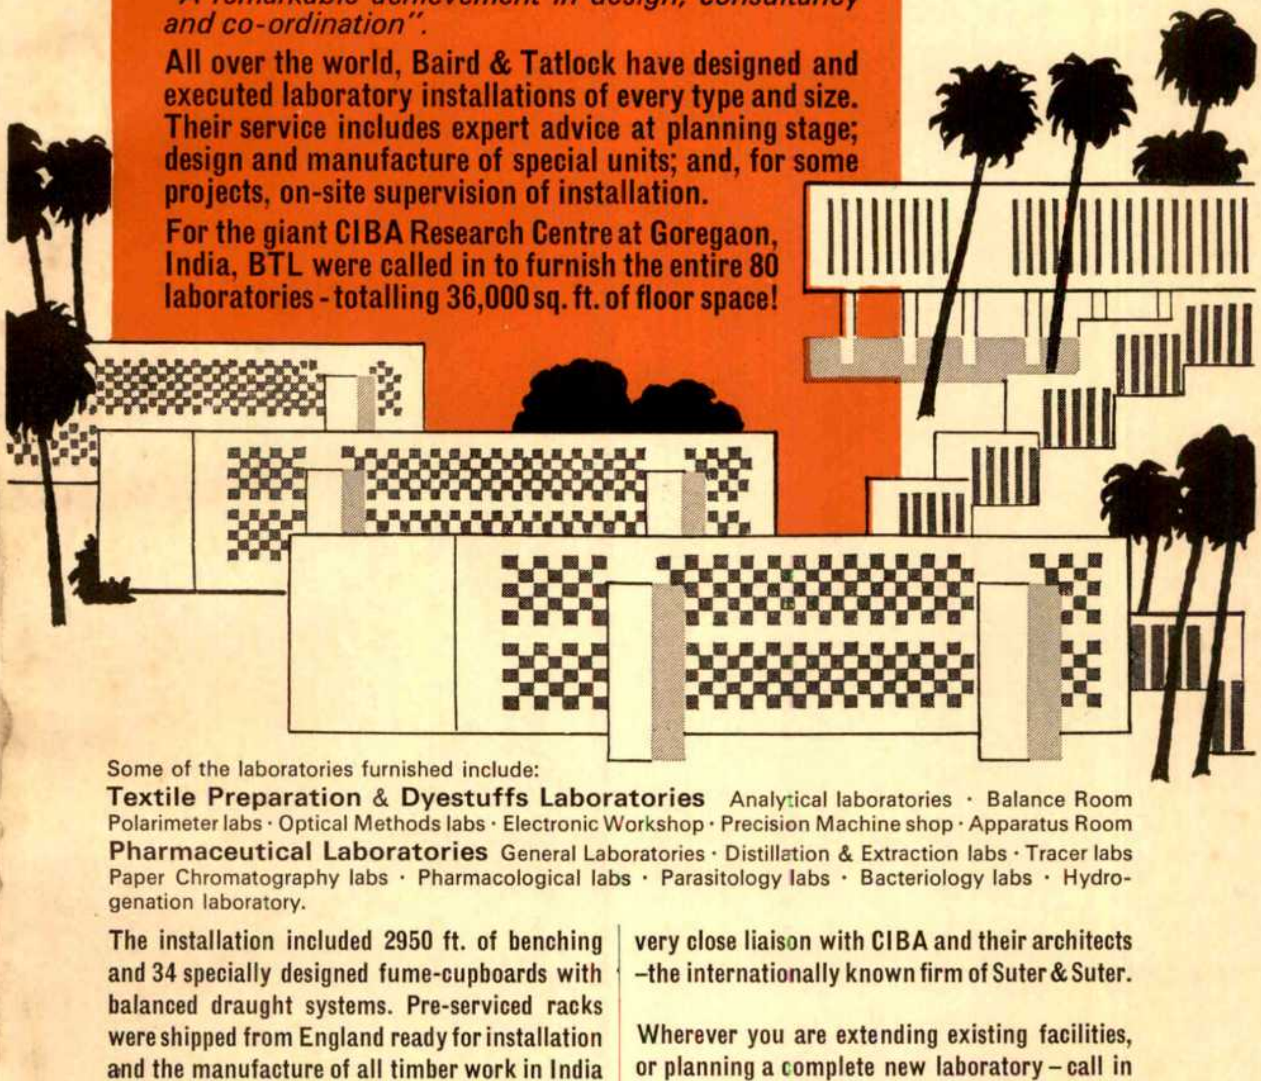
COMPLETELY FURNISH THE LABORATORIES OF SOUTH ASIA'S LARGEST RESEARCH CENTRE!

"A remarkable achievement in design, consultancy and co-ordination".

All over the world, Baird & Tatlock have designed and executed laboratory installations of every type and size. Their service includes expert advice at planning stage; design and manufacture of special units; and, for some projects, on-site supervision of installation.

For the giant CIBA Research Centre at Goregaon, India, BTL were called in to furnish the entire 80 laboratories - totalling 36,000 sq. ft. of floor space!



Some of the laboratories furnished include:

Textile Preparation & Dyestuffs Laboratories Analytical laboratories · Balance Room Polarimeter labs · Optical Methods labs · Electronic Workshop · Precision Machine shop · Apparatus Room **Pharmaceutical Laboratories** General Laboratories · Distillation & Extraction labs · Tracer labs Paper Chromatography labs · Pharmacological labs · Parasitology labs · Bacteriology labs · Hydrogenation laboratory.

The installation included 2950 ft. of benching and 34 specially designed fume-cupboards with balanced draught systems. Pre-serviced racks were shipped from England ready for installation and the manufacture of all timber work in India was closely supervised by BTL's design consultants, who, at all stages of the project worked in very close liaison with CIBA and their architects —the internationally known firm of Suter & Suter.

Wherever you are extending existing facilities, or planning a complete new laboratory — call in the BTL Furnishings Division! This is the first step towards the speedy and successful completion of your laboratory project.

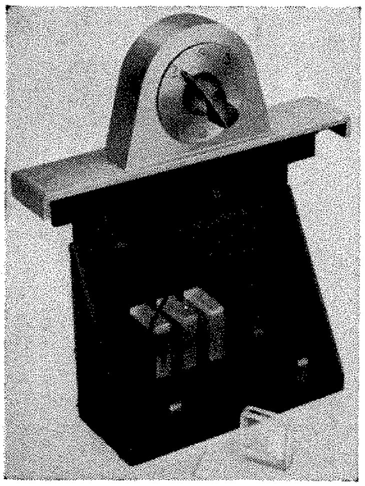
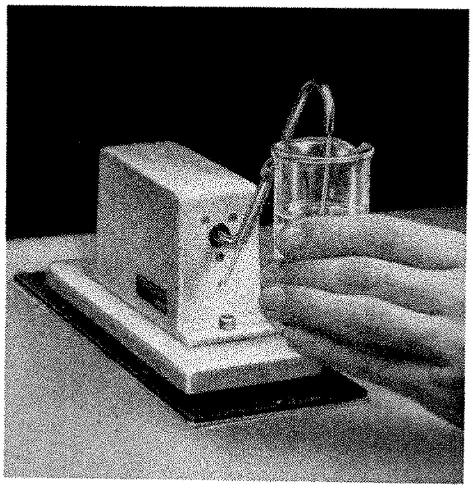
UNICAM

SP.600 with AUTOCELL

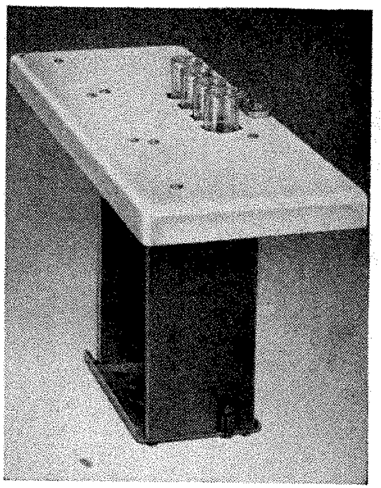
MICROCELL ACCESSORY AND TEST TUBE HOLDER



SP.680 MICROCELL ACCESSORY



SP.625 AUTOCELL



SP.630 TEST TUBE ACCESSORY

The Unicam SP.600 Visible Spectrophotometer is now available with the SP.625 Autocell Accessory; a unit which greatly reduces sample handling time. Also available is the SP.649 Power Supply Unit. This replaces the dry batteries normally supplied and provides an all-mains operation.

These latest developments, together with the SP.680 Microcell Accessory and the SP.630 Test Tube Holder, make the SP.600 Spectrophotometer the most versatile instrument for all absorption measurements in the region 360-1000 mμ.

The Autocell, Microcell and Test Tube Accessories are easily interchangeable and each is designed to fit into the cell well of the main instrument—no special fitting arrangements are necessary.

SP.625 Autocell

The new Unicam Autocell provides a completely automatic means of filling and emptying the special sample cell. One control is provided (see illustration above) and the operator can fill and empty the sample cell without any risk of cell breakage, sample spillage or contamination. This speeds analysis and greatly improves accuracy and reliability. The minimum sample volume required is 5 ml. Tests have shown that less than 1 per cent of sample volume remains after emptying. The sample comes into contact only with fine bore polythene or stainless steel tubing.

SP.649 Power Supply Unit

The Power Supply Unit has been designed to replace both H.T. dry batteries and can be easily fitted to every SP.600. It will appeal to those who require the extra convenience and reliability of an all-mains operated instrument. The unit consumes less than 5 watts and its output is unaffected by mains voltage fluctuations of +12½ per cent.

Full information on the SP.600 and its accessories will gladly be sent on request.

CHAPMAN & HALL

Some Recent Books

Industrial Ceramics

F SINGER & SONJA S SINGER

"It is likely that for many years to come this book will be regarded as the most authoritative in the vast field it covers All branches of industrial ceramics have been dealt with in such a way as to make the book equally valuable to the specialist and non-specialist. The material is presented clearly and straightforwardly, with a wealth of explanatory data and tables" *Ceramics* 1,455 pp Illus 12 gns

Molecular Stills

P RIDGWAY WATT

"The book is intended to provide a comprehensive guide to the design, construction and performance of open-path distillation units It fulfils this function admirably" *Industrial Chemist.* 360 pp Illus 70s

Industrial Applications of the Organometallic Compounds

J. H. HARWOOD

"The book is, in fact, much more than a literature survey of applications There is a great deal of well documented information on preparative methods and properties The author has made a most valuable contribution to the literature of this subject and his book is certain to be widely used in both industrial and academic research laboratories" *Chemistry & Industry* 462 pp. Illus 60s

The Shock Tube in High Temperature Chemical Physics

A. G. GAYDON & I. R. HURLE

"An excellent book on a relatively new and exciting topic The book has all the earmarks of a standard work in the field and bears the stamp of experience and authority" *Proceedings of the Physical Society* 307 pp. Illus 65s

11 NEW FETTER LANE, LONDON, E C 4

PRECISION INSTRUMENTS

Direct Reading Wavelength Spectrometer

This is just one of the many fine instruments of our manufacture that can be found in daily use throughout the world As a large range of accessories can be supplied with this spectrometer it is a really universal instrument

We will be pleased to recommend the equipment most likely to meet special requirements

Please write for full details to Dept N

A STIMULANT FOR BRITISH SCIENCE

THE sixteenth annual report of the Advisory Council on Scientific Policy *, covering the year 1962–63, was published shortly after the report of Sir Burke Trend's Committee on the organization of civil science †, in which the report of Sir William Slater's Committee on Research into National Resources appended to the Advisory Council's report, is discussed Even in that respect, the Trend Committee, while anticipating, does not lessen the interest of the Advisory Council's own report, which may indeed be scrutinized even more closely in the light of the Trend Committee's proposal to reconstitute the Advisory Council itself as a more authoritative and independent body Apart from this, however, the Advisory Council's report has features of particular interest in its comments on the European High-Energy Physics Programme, on scientific documentation and on research in oceanography and marine biology A brief note on the emigration of scientists is supported by a copy of a memorandum on the subject submitted to the Minister for Science last May

The report of the Advisory Council on Scientific Policy opens with a discussion of the report of the Committee on Scientific Manpower on *Scientific and Technological Manpower in Great Britain*‡, published early in October This has recently been discussed in these columns (*Nature*, 200, 297; 1963), and no more need be added here than that the Advisory Council reiterates its concern over the preference for science over technology which continues to be shown by the more promising entrants to the universities and the need for greater emphasis on post-graduate research in technology The Council's continuing concern over an adequate supply of supporting staff in the shape of technicians has now led it to institute an enquiry, under the chairmanship of Sir Willis Jackson who has now succeeded Sir Solly Zuckerman as chairman of the Scientific Manpower Committee, into the supply of and demand for such staff (see also p 1145 of this issue)

During the year, the Advisory Council was invited to advise the Minister for Science on the attitude the United Kingdom should adopt to the proposals in a report from a representative body of nuclear physicists, with Prof B H. Flowers as chairman, set up by the Joint Consultative Panel for Nuclear Research on the Department of Scientific and Industrial Research and the National Institute for Research into Nuclear Science The Advisory Council does not dispute this working group's belief that physics is to-day on the threshold of far-reaching developments which will come to fruition with a new theory of the nature of matter and of its fundamental interactions It is possible that, either at this stage or later, gravitation, the creation of matter and the problems of cosmology may be unified with high-energy physics Nor does the Council deny that Britain's national facilities for high-energy physics are now, or will be in the near future, bettered only by those of the United States, while through the European Organization for Nuclear Research, Britain has opportunities second to none The working group accordingly wishes Britain to continue to play a full part in European collaboration in high-energy physics even in the enlarged programme now proposed, which envisages *inter alia*, capital costs of £120 million over an 8 5 year constructional period, followed by operating costs of £20 million upwards, compared with the capital costs of the existing installation at the European Centre for Nuclear Research of some £20 million and current operating costs of £8 million, of which Britain's contribution has been slightly less than 25 per cent

The Advisory Council recognizes that nuclear physics is much more expensive than most other types of scientific work, but it recognizes also that Britain's expenditure on other scientific research is too low There is also a serious deficiency in provision for university research, the expenditure for the Research Councils is expected to increase at more than 10 per cent per annum In the circumstances, unless the Government is prepared to provide the relatively small sum needed to satisfy the legitimate needs of general scientific research in the universities by supplementing departmental research budgets, increasing the supply of technical assistance of all grades and creating more senior posts, the Advisory Council considers that it will not be justified in supporting the expenditure required to further these research proposals, good as they are in themselves It stresses, instead, the urgent need for international co-operation in this area and in that of space research

It is impossible not to believe that the Advisory Council is right to insist that these needs of the universities are primary and must be met first, not merely to avoid distortion of Britain's research effort in general but equally to avoid serious consequences in the universities and other institutions of higher education Nor is this opinion invalidated by the effects of the National Institute for Research in Nuclear Science and of the European Organization for Nuclear Research in attracting the return of physicists from the United States to use the new opportunities—which is noted in the Advisory Council's report, though not in its memorandum to the Minister for Science on the emigration of scientists That memorandum, after reviewing the report of the Royal Society's committee and other evidence, made six specific proposals for Government action, all of which are under consideration and on some of which action has already been taken

A review of salaries in universities by the National Incomes Commission is already well advanced Research Councils are already authorized to pay the university scientific departments an additional £200 per annum in respect of each holder of a postgraduate award, and the responsible bodies have already taken steps to minimize delay in the award of student grants and grants for specific research projects Besides increasing the number of senior posts in universities, the memorandum also suggested increasing the scale of technical assistance at all levels for university research, and awarding post-doctoral fellowships, to be held on their return, to outstanding men before they leave for research experience overseas, or placing a member of such fellowships at the free disposal of universities and governmental research laboratories

In these two matters alone, on the evidence of the present report, the Advisory Council is displaying a vision and an energy that has been lacking in some recent reports and which should preclude any hasty acceptance of proposals for its reconstitution—though not for strengthening its authority On scientific documentation, too, the Advisory Council shows a greater awareness of its responsibilities and opportunities, and although during the year the Department of Scientific and Industrial Research made its first grants to universities and colleges for research into problems relevant to scientific documentation, there is no doubt that the Advisory Council does, as it is already constituted to do, take a wider view than the Department The proposal to transfer such responsibilities to the Office of the Minister for Science, which will presumably be in close touch with the Advisory Council, is fundamentally sound and should also stimulate that essential wider conspectus of library resources and responsibilities which embraces the contribution of the National Central Library, the public library service, the university libraries and others, not to mention the new National Reference Library of Science and Invention, which is not mentioned in this report

This aspect could well be illuminated by the survey, which has already been put in hand, of the sources of information used by a representative sample of research chemists and physicists, and those working on the borders between these two subjects The survey asks for critical appreciations of the limitations of these sources and suggestions for improvement, and it also covers the storage and retrieval of information The Institute of Physics and the Physical Society, the Chemical Society and the Royal Institute of Chemistry have co-operated in selecting the sample and ensuring that it is representative

The Advisory Council also refers to the recommendation in 1963 by the British National Committee for Astronomy, following discussions between British and Australian scientists, that the urgent need for British astronomers to have access to a large-diameter optical telescope in the southern hemisphere could best be met by a joint British–Australian project for a 150-in instrument, sited in Australia, and working in close association with radio-astronomy. In reviewing in its 1959–60 report the balance of scientific effort in Britain, the Advisory Council noted the neglected position of optical astronomy and the interest and importance of the relatively unexplored southern sky No firm proposal had, however, previously emerged which could be put to the Government for decision, but the Advisory Council now strongly supports the view of this Committee and recommends that a design study should be undertaken as soon as possible

In view of the Trend Committee's recommendation regarding a National Resources Research Council, based essentially on the proposals of Sir William Slater's Committee, which has already been fully discussed in these columns (*Nature*, **200**, 1031, 1963), there is little to add by way of comment on the present report The Advisory Council agrees with the main conclusions of the Slater Committee but disagrees with the majority's view that responsibility for research in terrestrial ecology should be separated from responsibility for the establishment and management of nature reserves It considers, rather, with Sir Solly Zuckerman, that the whole of the Nature Conservancy's work should fall within the ambit of the proposed Council

Apart from this, it should be added on the subject that, besides its general discussion of the case for a new Research Council for Natural Resources, the Slater Report gives separate sections to the discussion of fisheries research, oceanography, hydrology, land use, terrestrial ecology, forestry research, soil science, and to the work of the National Resources (Technical) Committee The latter Committee was set up in 1950 in succession to the Imports Substitution Panel of the Committee on Industrial Productivity, and at present advises the Minister for Science and the Chancellor of the Exchequer on technical problems of the development, use and conservation of natural resources arising from considerations of the United Kingdom import and investment programme This Committee, the Slater Committee suggests, should come under the new Research Council and, with its staff, form an operational research unit in this field While agreeing that the laboratories of the various fisheries departments should also be transferred to the new Research Council, the Advisory Council was undecided whether the responsibility for the Torry Research Station should be transferred to the new Research Council or to the Agricultural Research Council, though it was satisfied that it should no longer rest with the Department of Scientific and Industrial Research Moreover, in view of the blindness of the Trend Committee regarding overseas research, it should be noted that the Slater Committee recommends that the proposed Research Council should be empowered to support or undertake research overseas, and it directs attention to the urgent need of many developing countries for expert advice in this wide field It is also to be noted that it visualizes the resultant important contribution to technical aid as being of benefit to British scientists as well as to the developing countries themselves

The Slater Committee, as just noted, discussed the organization of research in oceanography although this was not included in the list of subjects which it was originally asked to consider The final section of the present Advisory Council's report considers at some length the question of research in oceanography and marine biology However, it does not comment specifically on the recommendations of the Slater Committee in this field In these recommendations it was proposed to place the administrative responsibility for the National Institute of Oceanography with either the Admiralty or the new Natural Resources Research Council, which should, in any event, take over the scientific and financial interest of the Development Commission in the Institute and should be authorized, directly or through the Institute, to undertake or support oceanographic research in any part of the world

The Advisory Council on Scientific Policy has not, however, completed its own survey of oceanography and marine biology, and its comments in the present report are limited to the work of the institutions already considered In 1961, the Council was requested to consider the Royal Society's proposals concerning Britain's participation in the International Indian Ocean Expedition and for general expansion in the marine sciences. Twenty nations and some forty research vessels are participating in the Indian Ocean Expedition, in which Britain is playing a full part in the form of a well-diversified investigation of the north-western area of the Indian Ocean The principal geophysical aim is to establish the crustal structure of the Arabian Sea and to determine its relation to the surrounding continental land masses, while the biological programme, besides covering the descriptive biology of the Arabian Sea, aims at investigations of the cycle of events in a typical upswelling region, and of variations of fertility in relation to present-day boundaries and crater layering

Commenting specifically on the National Institute of Oceanography, the present research programme of which covers a wide range of physical, chemical and biological investigations, the Advisory Council points out that its grant-in-aid has increased from £175,000 a year in 1961–62 to £360,000 for 1963–64, and that in the period 1961–63 the new R R S *Discovery* was built at a cost of £800,000 The Institute's staff of 25 in the scientific officer class on April 1, 1960, is expected to total 35 on March 31, 1964 On the work of the Development Commission, the Advisory Council points out that total grants by the Commission to the independent marine biological institutions at Plymouth, Edinburgh, Millport on the Clyde, Port Erin and Cullercoats, have risen from £209,500 in 1960–61 to an estimated £257,900 in 1963–64, while contributions to university research in oceanography in 1962–63 exceeded £4,000, some £90,000 being allocated for this latter purpose by the Department of Scientific and Industrial Research There were 654 students in 1962–63 taking special subjects related to marine biology as part of honours courses compared with 450 in 1959–60 and 81 postgraduate students compared with 39, while six universities were providing undergraduate courses in oceanography

The Advisory Council is much impressed with the progress which has been made in what it regarded in 1959–60 as a relatively neglected field, but, as already indicated, its full comments are reserved until it has completed its survey of other institutions supporting work in this field, on which the aggregate research expenditure in 1962–63 was a further £725,000 Meanwhile, here again it seems clear that the Advisory Council is fully competent to discharge the responsibilities that are already placed on it for co-ordination and advice over the whole field of science It would seem that given the adequate staff stressed by the Trend Committee it should be able to meet any further responsibilities which may fall to it from the expansion of those of the Minister for Science

There may be real substance in the recommendations of the Trend Committee that its authority should be strengthened and that its value would be enhanced by widening the basis of appointing its members and ensuring that they were independent rather than official representatives Nevertheless, there is much in the Advisory Council's present report to restore confidence in the judgment and independence of the Council which some of its recent reports have shaken and to demonstrate that it can be an effective instrument if wisely and firmly used The Advisory Council is to be congratulated on a fine report, which should be carefully studied by all responsible for taking decisions on the future organization of civil science in Britain If in the event this report should prove to be the 'swan song' of the Advisory Council as at present constituted, it is not one of which the Council need fear reproach

THE WONDERS OF PSYCHOTHERAPY

A Study of Brief Psychotherapy

By D H Malan (Mind and Medicine Monographs, No 8) Pp xiv+312 (London Tavistock Publications (1959), Ltd , Springfield, Ill Charles C Thomas, 1963) 35*s* net

Therapist–Patient Expectancies in Psychotherapy

Dependency in Psychotherapy

A Casebook By Prof William U Snyder Pp viii+424 (New York The Macmillan Company, London Collier-Macmillan, 1963) 70*s*

RESEARCH in psychotherapy has for long been the despair of experimentally minded psychologists, and while there are some gleams of light contained in the books under review these are not really sufficient to consider the gloom any less inspissated than before The crucial question that confronts psychotherapists is a very simple one, does it work ? Curiously enough this is precisely the question that psychotherapists have always avoided, relying on assumptions, persuasion and sheer accumulation of clinical anecdotes, rather than scientific demonstration Gradually the repeated criticisms of this unverified assumption have caused more and more analysts to acknowledge the sad deficiencies of their discipline, and now even the Tavistock Clinic, previously among the most reluctant to admit the point, joins the majority by admitting, in the words of D H Malan, the senior hospital medical officer "that there is not the slightest indication from the published figures that psychotherapy has any value at all" If the acknowledgment of ignorance is the beginning of the acquisition of wisdom, then we may perhaps regard this as one of the few rays of light mentioned above

For the rest, alas, Dr Malan's book falls into all the traps which have beset the task of previous workers who have tried to produce evidence in favour of psychotherapy in general or a special type of psychotherapy in particular Malan tries to show that brief psychoanalytic therapy is possible even with relatively severe cases of neurosis; he does this on a very small group of about twenty cases, which he admits to have been very highly selected indeed There was no control group and consequently no assessment of the likely role of spontaneous remission was possible Malan argues, not entirely without reason, that the short duration of the treatment and the chronic nature of the disorders militate against an argument based on spontaneous remission, in view of our lack of detailed knowledge of the occurrence of spontaneous remission in the type of case treated, this argument will appeal more to the converted than to those whose minds are still open

Malan's reasons for accepting the efficacy of psychotherapy appear to be based on the belief that the standards of cure adopted by analysts are higher than, and different from, those used by behaviour therapists This may be so, the example he gives does not suggest, however, that this is very likely, and the fact that many behaviour therapists started out as trained psychoanalysts would also seem to speak against it In any event, if psychoanalysts adopt different criteria we must ask for some evidence that these criteria are relevant and refer to something which can be demonstrated to exist, if a patient complains of impotence, it would require a good deal of demonstration to show that to relieve him of this impotence is not to cure him, and that what is required in addition (and possibly in lieu) is to give him insight into his Oedipus complex !

Malan gives some statistical treatment of his data, undeterred by the small number of cases (which he acknowledges as making this enterprise rather hazardous) or by the fact that the very curious method of selection does not make them representative of any conceivable universe of patients, thus making the application of statistical methods relatively unrewarding Altogether Malan is clearly not very sophisticated in the use of statistical methods, his assertion on p 173 that two-tail tests must be used when a prediction has been made but the correlation found is of the opposite side to that predicted is quite fallacious The reader obviously cannot rely for statistical guidance on the author of this book, and this makes it all the more difficult to evaluate his conclusion that brief psychotherapy is useful in certain types of cases, or his attempted demonstration of some of the correlates accompanying improvement However, when all is said and done this is nevertheless an interesting book, sophisticated in many ways, and more aware than most of the pitfalls and difficulties attending rigorous demonstration in this field It is a pity that Malan has fallen prey to the prevailing belief among psychotherapists that to acknowledge a deficiency in a research design makes it unnecessary to improve the research design in such a way that the deficiency is removed

Goldstein's book is a purely argumentative one containing no new material It has an unusually high ratio of references to text, there are 121 pages of text and 342 references In parts the book reads as if the author had handed his secretary his reference cards with a few comments scribbled on each, with the instruction of typing it all into one consecutive text The theme that seems to run through some of this display of erudition seems anchored in the placebo effect—and it is characteristic of the author that he cannot even tell the reader what the word means in English without having to put in a reference to somebody else

What Goldstein says in brief is that the notion of spontaneous remission is erroneously labelled and that expectations on the part of the patient aroused by such things as registering for assessment, being administered personality tests, etc , have an important part to play in his recovery These placebo effects are indeed important, but it is difficult to think of anybody who has written on spontaneous remission who has not held a similar view Obviously while spontaneous remission occurs in time it is not effected through the passage of time alone, it has always been regarded as a task for further research to establish just precisely what are the agencies responsible for spontaneous remission Learning theorists, for example, have implicated extinction as a possible mechanism, but this whole school is completely neglected in Goldstein's discussion What the notion of 'spontaneous remission' maintains is essentially that the remission occurs without benefit of explicitly formulated and planned psychotherapy on the part of a trained psychotherapist, by using his own notions of what might be meant by spontaneous remission, and by disregarding the accepted usage, Goldstein manages to build up a man of straw which he then demolishes amidst universal merriment It is not obvious what useful purpose is served by this exercise

Snyder's book rouses one's worst fears, indeed, in some ways it had better be called a non-book Recent developments in American psychology had led one to a nightmare of patients' outpourings under psychotherapy being taken down on a tape recorder, typed out by a secretary and immediately rushed to the publishers without intervention of any form of critical reasoning This book approaches the ideal although not quite reaching it, the two cases recorded are edited rather than being quoted in full, but nine-tenths of the book is still made up of the tape recordings as they came from interview They are meant to illustrate the principle of 'dependency' in psychotherapy which I myself found too nebulous to state in brief, their purpose, apart from acting as an illustration, appears to be to help in training future psychotherapists It is difficult to see what they can possibly learn from this agglutination of verbiage, or what relationship, however tentative, there can be between what apparently goes on in this 'dependency' relationship and science Strictly speaking this book cannot be reviewed at all, not being a book in the ordinary sense, it will presumably be studied and acted on by Snyder's students, but it is unlikely that anyone else would want to read it or derive any benefit from doing so There is, it should be added, a brief introduction dealing with some research accounts in this field, but these do not enlighten at least one reader as to the meaning and usefulness of this book H J EYSENCK

NUCLEAR INSTRUMENTATION

Proceedings of the Symposium on Nuclear Instruments, Harwell, September 1961

Edited by J B Birks Pp vii+251 (London· Heywood and Co , Ltd , 1962) 60s

Nuclear Instruments and Their Uses

Vol 1 Ionization Detectors, Scintillators, Cerenkov Counters, Amplifiers Assay, Dosimetry, Health Physics (National Academy of Sciences—National Research Council) Edited by Arthur H Snell Pp 494. (New York and London John Wiley and Sons, Inc , 1962) 57s

WE have moved a long way from the ionization chambers and Geiger counters which were used with the 37-in cyclotron at the time of Rutherford's death in 1937 Progress has been far more rapid in the sophistication of the experiment and the saving of the physicist's time than in almost any other branch of human affairs, and the meeting in Harwell which succeeded the Rutherford Conference reviewed the armoury of techniques now available for a renewed attack on the outstanding problems of nuclear physics There were three main sessions two on particle recording devices, operating either by the light emitted or, in the case of the semiconductor, by the conversion of particle energy into an electrical pulse, the third session was on recording of complex data

Prof McGee described the construction and output of photo-electric image intensifiers to record the faint light emitted by high-energy particles passing through scintillation chambers, some show a light gain of a thousand, some have been developed as gates shutting in a microsecond, phosphors may be chosen to store for a microsecond or a minute, but these devices are at present restricted to a few special experiments—a typical use is given in the recording of weak interactions of mesons There is some useful information on the statistical properties of scintillation counters, the time taken to deliver a signal from one photo-electron, and the total time of operation of the photo-multiplier Recently liquid helium has been shown to be a good scintillator, emitting light in the far ultra-violet which is not seriously attenuated in the liquid and may be absorbed by a phenyl to give a visible light pulse

The semiconductor particle counters are being developed at high speed, but the Conference did not devote much time to descriptions of these, one paper discusses the effect of imperfections of a liquid-air-cooled silicon crystal on the current pulses released by fast ions passing through the crystal in different directions, but energy resolution can be disappointingly small Very thin counters can be used to distinguish between the ionization of particles of different mass but of the same total energy before they enter a detector to measure their total energy Neutron counters depending on neutron induced reactions in the counter have been developed in Harwell, they can be so compact that they cause little modification to the neutron flux, the proton recoil counter has a polythene layer in contact with a silicon surface barrier detector, the helium-3 counter is a gas layer of helium between two silicon detectors

There are several papers on the spark discharge chambers used for tracking multiple events arising from cosmic rays or high-energy particle accelerators, one simple application is as a speedy check on the exact location and shape of the beam emerging from a machine operating at hundreds of cycles per second High efficiency of discharging is essential if a multiplicity of events is to be recorded over a large volume, yet spurious sparking must be suppressed Neon/helium mixtures have been shown to be the best with methane to quench the discharges, and these have an efficiency of nearly 100 per cent and are markedly superior to the earlier argon-filled chambers For work involving merely deflexion in a magnetic field thin-plate electrodes are used with a $\frac{1}{4}$-in spacing, but absorption experiments may be performed with thicker plates of various elements There seems to be a difference in experience with chambers sealed, or flushed continuously with gas

The third and fourth sessions were devoted to improvements in the recording of complex electrical signals derived from the detection of nuclear events Three papers from Saclay review the conditions to be satisfied in setting up automatic experiments in nuclear physics, and extreme reliability of components is emphasized with repeated checks on the operating accuracy of the computors used An ingenious improvement in the storage of information on a magnetic tape by the use of a multitrack recording head was described and papers were given on sophisticated multi-channel pulse height analysers

The second book is a really comprehensive text-book on nuclear instruments compiled by seven authors, mainly from the Oak Ridge Laboratory, and each chapter is extremely well supported by bibliographical references so that the book will serve the advanced student and also the research scientist very satisfactorily Ionization chambers proportional counters, Cerenkov counters and scintillation counters are described in great detail with full accounts of the theoretical considerations on which they are based, and these chapters are followed by a detailed account of the construction and operation of electrometers and amplifiers The last three chapters concern the measurement of radioactivity, dosimetry and personnel monitoring, chapters invaluable to the scientists in many disciplines using trace elements and responsible for the safety and health of operatives in laboratories, factories, or at nuclear power stations The seven authors and the editor have generously contributed their efforts on a royalty-free basis, and the 500-page book is commendably cheap for the wealth of information it contains

The fundamental processes involved in creating ionization in gases by fast and slow electrons and charged atoms are described in detail in the opening chapters, with attention directed specially to the importance of gas purity if true distinctions are to be drawn between ionization in different gases Fast counters only collect the electrons produced in the gas. ignoring the positive and negative ions which have far lower mobility, so gas purity is also important to avoid electron capture by electro-negative gases, a full account is given of the factors including geometric which affect electron collection The importance of purity is enhanced in chambers operating at high pressure, for example for γ-ray absorption experiments, and details are given of methods to purify the gases commonly used The proportional counter which operates by amplification of primary ionization in the high field surrounding the collector electrode has found its greatest application in recording quanta of low energy, for example from 250 eV upwards, and the chapter discusses resolution, proportionality and calibration of counters operating on this principle

The application of the scintillation counter to the efficient detection and spectroscopy of nuclear radiations arises because charged and uncharged particles and gamma-rays having a wide range of energies can be wholly absorbed in the scintillator and the light output is nearly proportional to the absorbed energy Moreover, the light is emitted in an extremely short time, so resolutions in the millimicrosecond range can be obtained Brief accounts of the growing of inorganic crystals are given together with the scintillation properties of the most important with their activators, why some halides are efficient scintillators and others are not is still a mystery Organic crystals of the aromatic hydro-carbons are efficient scintillators if very pure and plastic scintillators can be made by dissolving in polystyrene made from the very pure monomer freed from dissolved air· as they can readily be made very large they are efficient detectors of fast neutrons A second solute may be used to convert the fluorescent radiation to a spectrum more acceptable to the photo-cathode utilized in the multiplier For very large volume detectors for very fast particles organic liquids may be used, the solvent acting as the stopping medium, the solute, the fluorescent or wave-length shifter Extreme purification is necessary, oxygen must be removed for reasons not fully understood Many solutes have been tried and the solvent may be loaded with boron or cadmium salts if neutron detection is required or with heavy elements for γ-ray detection

The latest addition to the scintillation detector is the family of noble gases, but they need to be very pure and then to be mixed with wave-length shifters Their use is specially for the heavier charged particles, the light output per unit energy being insensitive to the charge or mass of the particle stopped in the gas

The optical coupling between scintillator and photomultiplier tubes is briefly treated, together with characteristics of many tubes, and there is a long and informative account of many types of experiments using these counters

Cerenkov counters find their application in detecting particles of extremely high energy They use the shock wave emitted when particles travel through them with speeds higher than the velocity of light in them, and the angle of emission depends on β n (refractive index, *n*) They therefore at once discard all particles below a threshold velocity, and typical of their use is the detection of mesons in a high background flux of neutrons and knock-on protons Focusing and non-focusing types of detectors are well described, transparent liquefied gases. and water may be used to record electrons from 300 keV upwards and heavier particles in the multi-MeV range Wave-length shifters may be used, and then the light emission is isotropic A careful analysis of the efficiency of collection of light in the counter concludes an invaluable chapter

The chapter on d c measurement of the outputs from ionization chambers and the pulse amplification for spectral analysis of the output from the many counters is very comprehensive, advanced theoretical analysis is coupled with many practical details to be observed in the choice and assembly of components

The last three chapters deal with the techniques used in radiation measurements and will be of value to a wide range of users who may not necessarily be specially concerned with the physical principles of particle detection and the circuits of recording devices, other physicochemical methods of radiation measurement are not dealt with β-Counting is dealt with first, as the many disturbing factors such as absorption. back reflexion, sample covering and geometry are perhaps more important than for α or γ-rays The application of the 4-π counting technique has been greatly enhanced by the crystal and liquid scintillation counters, as samples may—in certain cases—be placed in the scintillator or in a cavity within it The points needing extreme care for absolute measurements are most clearly stated with adequate references to original work where the greatest precision is expounded For α-counting the problems are similar, though less onerous than for β- and for γ-counting the scintillation method is rapidly replacing all others due to its high (nearly 100 per cent) efficiency There are important corrections to be made for geometry and γ-escape, and the 'total intrinsic efficiency' of a scintillation counter is exhaustively treated

The chapter on dosimetry is confined to fundamental concepts and present trends when dealing with physically (physiologically) significant doses, and in Chapter 7 most explicit details and instructions are given for people working with sources of and in excess of microcuries There is a short historical account of the way the 'safe' exposure dose has been arrived at over the past thirty years culminating in the 1959 recommendations for operatives exposed to different kinds of radiations, it is good to note that the author and most health physicists dealing with people continuously employed in a radiation field divide even these conservative figures by a further ten The improved film meter is advocated for personnel monitoring, and many instruments for surveying are described General guidance is given for waste disposal and accidents The health physicist—a new and rapidly growing profession—needs to know every word of this account T E Allibone

WORKING UNDER PRESSURE

Solids Under Pressure

Edited by William Paul and Douglas M. Warschauer (McGraw-Hill Series in Materials Science and Engineering) Pp xvii + 478 (New York McGraw-Hill Book Company, Inc ; London McGraw-Hill Publishing Company, Ltd , 1963) 116*s* 6*d*

A WIDE variety of investigations, which have been conducted at high pressures, is reviewed in this book, but descriptions of high-pressure techniques are excluded almost entirely—apart from a special bibliography at the end

Having chosen a connecting thread, the editors would seem to have pulled it, but the result is a book which is unusually easy and entertaining to read This is in part due to the fact that, with a new parameter to be varied, the simplest properties of the simplest solids are the first objects of exploration The bases of familiar theoretical models are, therefore, probed afresh, and most of the chapters in this book involve re-statements of these basic models from slightly unfamiliar points of view (hence the entertainment)

My guess is that many physicists have the notion that the results of measurements at high pressures are only rarely of much significance, and that the experiments themselves are always of the brute-force varieties This book would dispel such views There are great difficulties in the way of achieving hydrostatic conditions at pressures in the megabar range, but up to 30 kilobars there is standard and not too elaborate equipment now available and measurements of high resolution and of several different kinds can be made The same is true of pressures up to 100 kilobars in specialist laboratories Pressure might not rival temperature as a parameter, the variation of which can produce large and significant changes in the behaviours of solids, but it is clearly catching up This is a timely situation, because there is an increasing need to separate those parts of a change in behaviour with temperature which are explicitly temperature-dependent, on one hand, and implicitly temperature-dependent (for example, via lattice expansion) on the other Ancillary measurements at high pressures make this possible and there are several examples in the book The present-day theoretical concern with interactions between quasi-particles (lattice-waves and spin-waves in particular) makes this separation particularly desirable

Eighteen authors contribute fourteen chapters on equilibrium, transport and activation properties, and phase transitions, involving descriptions of optical, magnetic elastic, thermal and other measurements The whole book is addressed as a tribute to Prof Bridgman, whose death regrettably preceded the publication He contributed the introductory chapter, and the rest of the book illustrates the first steps in his vision of the future of high-pressure research as a progressive delocalization of electrons in successive atomic shells

D H Martin

TEXTILE PHYSICS

Physical Properties of Textile Fibres

By Prof W E Morton and Dr J W S Hearle Pp xxi + 608 (Manchester The Textile Institute, London Butterworth and Co (Publishers), Ltd., 1962) 105*s*

A COMPENDIUM of information, dealing with a subject wide enough for no one to be master of all of it, tends to be received with opposite comments according to the self-control of the reader He is tempted to look first at the part dealing with his own speciality The result will be a criticism—none of us approve of encyclopædia articles on our own subjects (unless, indeed, we have written them ourselves) But this is to misuse the book, its proper role is to help us to look up other people's subjects as may be necessary, even if superficially, so that we do not have to pester our colleagues Who, then, could safely write a book like this ? Obviously a teacher, for he alone in our sadly specialized world has to maintain more than a passing interest in all branches of his subject *The Physical Properties of Textile Fibres* is just such a book, and it is fittingly written by a professor and a senior lecturer at the Manchester College of Science and Technology It made a good first impression, and was accordingly subjected to the stringent test of being lent to various colleagues of mine with a request for their opinions on parts dealing with their own topics In no case was there an adverse report—this is high praise

After an introductory chapter on fibre structure, which may be regarded as setting the background for the rest of the book, there is a long section on fibre dimensions and their measurement, followed by sections on density, moisture relations and effects, mechanical, electrical, optical and thermal properties, and, finally, one on friction Throughout, the treatment preserves a good balance between methods of measurement, results specific to particular fibres, and discussion of their meaning The accounts of methods are critical where required, and attention is given to that especial plague of textile physics —variation in results—and how to deal with it The methods of measurement described are not only those used in research laboratories, methods used in industry are given a fair share of attention, though in all cases the emphasis is on principles rather than on practical details (which are available elsewhere)

The book is well supplied with diagrams, and data are presented by graphs rather than tables wherever possible Here arises one of the few criticisms that can be made where data are to be read from graphs in a book, it is convenient if the scale of reproduction is such that the units are simply related to centimetres or inches so that a ruler can be used without paper calculations This is not often done, but it would be a welcome novelty In the present book some 50 per cent of the graphs do comply with this requirement, but the remaining 50 per cent are reproduced just a little too big or too small When the book comes to a well-deserved second edition, may we have these adjusted ?

The lists of references, always an important part of a book like this, are adequate so far as can readily be seen, where faults are usually those of omission

Occasional blemishes occur, for example, at the bottom of p 105 some of the instrumental parts referred to by letter are not present in the appropriate diagram, and there are a few rash statements such as that in the last sentence on p 522, where the authors speak of " the hygroscopic salts which are the most effective anti-static agents . ", but these lapses are few In general, the book can be warmly recommended to all textile physicists who can afford to pay the price P S H Henry

THE CRIPPLED MIND

The Biology of Mental Defect

By Prof L S Penrose Third edition, completely revised with the assistance of J M Berg and Helen Lang-Brown Pp xxiv + 374 + 8 plates (London Sidgwick and Jackson, Ltd , 1963) 42*s* net

THIS book is a new edition of Penrose's classic revised by the author and two of his assistants, J M Berg and Helen Lang-Brown It is an excellent book, and gives the latest knowledge of this difficult subject

Forty years ago mental deficiency was regarded as more or less an impenetrable mystery Not that many felt it was worth while spending their time trying to investigate it Indeed, it was the most disregarded waste-land of a neglected area of medicine Psychiatry was considered unworthy of the orthodox physician's interest and mental deficiency more or less hopeless from the start Imbeciles were herded into vast buildings which were little better than prisons, and idiots put into special hospitals where they were merely kept alive There was practically no attempt to understand the condition, and any idea of treatment or prevention would have aroused ridicule

Naturally, the literature devoted to such a condition was on a similar level Text-books were few and devoted mainly to anecdotal cases on which were built theories based on conjecture These were copied from one text-book to another and dated back to such theorists as Lombroso with his celebrated ideas of 'degeneracy', which was an inherited state and condemned the sufferer not only to a hopeless life but also any progeny he might have to a similar fate Indeed, according to Mott, any children of a defective were due to an even worse end because of his theory of 'anticipation' which implied that once the germ plasm was damaged it tended to deteriorate more and more through the generations Another theory of that time was 'blastophoria', or damage to the germ tissue, put forward so enthusiastically by Forel He believed that this damage was caused by alcohol and similar poisons, in spite of the fact that in many cases there was no particle of evidence that the parents had ever used alcohol or suffered from any form of poisoning

These theories became modified by time, and it was thought that mental defect was due to injury to the brain through trauma or infectious disease This was usually attributed, since it was possible to detect that the child was abnormal at birth, to some intra-uterine condition The alternative view was that defect was caused by 'neuropathic diathesis' which was inherited, and was only a more scientifically sounding name for Lombroso's 'degeneracy

All these theories were blown away by the patient work of Penrose, who produced statistics which shattered them In 1933 he published his book, *Mental Defect,* and suggested that the condition was due to a multiplicity of causes He followed this up with statistical proof in his *Colchester Survey* for the Medical Research Council in 1938 His *Biology of Mental Defect,* published in 1949 and revised in 1953, was soon a classic, and the new edition will be unchallenged In it he reviews the new developments The great discovery that such conditions as mongolism are due to cytological abnormalities, the commonest being the extra chromosome Again the revelation of the biochemical factor, phenylketonuria, is likely to lead to other advances

J B S Haldane, who writes a foreword to the new edition, suggests that these discoveries will finally lead to the elimination of a quarter of the defectives This is true, but the discovery of where to look and the sort of advances which can be made will inevitably lead to other points of progress

One can sum up by saying that this excellent book should be in the possession of every psychiatrist, geneticist and research worker interested in mental defect He will find in the descriptions valuable ideas, and in the forty-one pages of references material for a great deal of future work

The book is well bound in dark blue cloth, has clear print, and a full index Clifford Allen

ARCHÆOLOGY IN THE TRANSVAAL

Prehistory of the Transvaal

A Record of Human Activity. By Revil Mason Pp. xxiv + 498 (257 figures) (Johannesburg Witwatersrand University Press, 1962) R 6; 60*s* , 8 70 dollars

DR MASON'S book is unfortunate in that it is published at a time when inter-disciplinary studies of archæological remains are opening up new possibilities of understanding prehistoric peoples. The application of scientific techniques, such as pollen analysis and radiocarbon dating and the statistical analysis of assemblages of artefacts, are together forming a basis for future studies of the relationship of man to time and environment

It is, therefore, disconcerting to read that in Dr Mason's opinion little reliable work has been done in the Transvaal on phenomena which indicate climatic change and that prehistoric remains are also not likely to provide an accurate reflexion of environment In consequence, environment is discussed in terms of a simple territorial division for descriptive purposes only Elsewhere, he states that it seems doubtful if the radiocarbon dates from the Transvaal can be accepted and also that geological interpretations so far put forward are often unsatisfactory It is, therefore, apparent that this book does not offer the fuller picture of prehistory to which archæologists in recent years have become accustomed and that, by and large, Dr Mason has not been able to apply in full the correctives of available scientific techniques to typological hypotheses

There is, however, an analysis of the artefacts from many sites in the Transvaal For the most part this is a simple numerical analysis of defined tool categories In defining these categories Dr Mason is faced with the dilemma of whether to make them so wide that essential differences may be obscured or so numerous and narrow that they may be ill defined He has chosen the former alternative and on this basis has attempted even an inter-continental comparison between Transvaal sites and two Mousterian sites in France Without geographical limitation or environmental comparison it is doubtful whether or not comparisons based on such a small sample are of value Indeed, simple numerical or metrical analyses of tool types are not likely to be regarded in future as sufficient, in view of the more complex statistical analyses now used in Europe and the United States There is, however, a body of information of use to research workers

There are, in addition, many drawings and photographs of artefacts, some imaginative drawings of life in the Stone Age which may have some popular appeal and which have been executed with attention to the known facts, and some excellent reproductions of rock art There is a good bibliography

On the whole the book may appeal more to the layman than to the professional archæologist, but Dr Mason's resolute refusal to accept ready-made conclusions drawn from evidence which he believes to be inadequate or wrongly interpreted is of value to African archæology, and so are his attempts to solve debatable field problems by direct personal action E S Higgs

La Mesure des Températures au Laboratoire et dans l'Industrie

By M Terny Pp xv+320 (241 figures) (Paris Dunod, 1962) NF 48

THE emphasis in this book is much more on the industrial than on the laboratory problems of temperature measurement. For example, though the interpolation formulæ used for standard resistance thermometers are given, the only thermometers described are industrial types with which these formulæ are not normally used Moreover, it is implied that the potentiometric method is the only way in which an accuracy of 0 001° C can be attained, whereas this method is being steadily displaced by bridge methods in all parts of the world.

The book has much too large a number of errors, ranging from typographical slips to definite mis-statements On p 11, for example, it is stated that the maximum difference between the International Practical Scale and the thermodynamic scale up to temperatures of the order of 500° C is 0 01° C In fact, measurements by different workers with the gas thermometer at 444 6° C show differences ranging from 0·07° C to 0 10° C We are told that the wire method for the determination of melting-points is used for silver and gold in practice, it is used for gold and palladium, and it would certainly be difficult to use it for silver.

From p 9 one infers that the International Scale dates from 1948 (when it was revised) instead of 1927, though the correct date is given on p 117, where the lower limit of the scale is given as −190° C. This was in fact true in 1927, but it was soon found that extrapolation below the oxygen boiling-point was unreliable, and the scale was limited to −182 97° C at the earliest opportunity On p 293 the triple point of benzoic acid is incorrectly given as 112 36° C, while the correct value (122 36° C) appears on p 110, but is ascribed to the melting-point

It is a pity that a book which contains a good deal of information that might be useful to the industrial user of temperature-measuring equipment should have so many errors (those cited here are only a representative sample) that one can have little confidence in it J. A. HALL

Chemical Calculations

An Introduction to the Use of Mathematics in Chemistry

By Prof Sidney W Benson Pp xii+254 Second edition (New York and London John Wiley and Sons Ltd , 1963) 23*s*

CHEMICAL Calculations contains problems covering the Advanced and Scholarship Levels of the General Certificate of Education A large number of these are realistic and interesting; those on atomic and molecular dimensions are particularly attractive and are introduced early in the course—a most valuable idea Unfortunately they are mixed up with mere arithmetical exercises such as: "What is the weight in tons of 120 mg of radium?" Chemistry teachers often find it necessary to teach sixth formers a little arithmetic, but to do it by purchasing books like this would prove very expensive

There are sections dealing with basic mathematical techniques such as using indices, logarithms or obtaining approximations These are quite unnecessary for pupils studying mathematics for Advanced Level examinations, and would prove inadequate for the person who needed to read them A serious attempt is made to help those who have difficulty with the notion of proportionality, which after all is involved in most calculations at this level The rigorous use of units is to be recommended

The laws and theories of the subject are stated clearly and are illustrated by worked examples Laws are often derived and the whole appears to progress in a logical manner Often the derivations are unsatisfactory and there is insufficient stress on the experimental nature of chemical laws

The book seems to fall between two stools On one hand it is a most expensive source of problems, on the other it is a very inadequate physical text

D C FIRTH

Interfacial Phenomena

By Prof. J T. Davies and Prof. E K Rideal. Second edition Pp xiii+480 (New York Academic Press, Inc ; London. Academic Press, Inc (London), Ltd , 1963.) 107*s* 6*d*

THE second edition of this excellent and stimulating work has appeared barely two years after the first (see *Nature*, 193, 408, 1962) this is of itself a striking tribute to its value and importance Changes from the first edition are not great, the sections on circulation in moving drops and on wave-damping have been re-written, and some corrections and clarifications have been made The pagination is practically the same, except for the subject index which has been rearranged and enlarged In the heading of one chapter, on transport of material across interfaces, the word 'diffusion' has been altered to 'mass-transfer'

The great merit of the book is in its clear and original presentation of modern developments, not a few of which are advances made by Davies The electrical properties of interfaces are introduced quite early in the book· the treatment of adsorption at liquid interfaces is largely original There is a very good chapter on chemical reactions at interfaces, a subject very largely due to Rideal and those inspired by him Two topics of much practical importance, to which Davies himself has contributed a great deal, are the movement of material across interfaces, and surface viscosity and its importance in wave-damping All these topics are put into proper perspective against the classical, older parts of surface chemistry, which is concisely and adequately given, though in less detail than in some other books

This book is the result of some forty years' pioneering research by the senior author, and about twenty years' by the junior author it is a very well-considered exposition of much of their work, put into clear relation with the work of many others N. K ADAM

Five Years' Work in Librarianship 1956–1960

Edited by P. H Sewell Pp viii+559 (London The Library Association, 1963) 180*s* , non-members, 135*s* , members

LIKE its predecessor for the years 1951–55, this volume covers developments in librarianship over a period of five years and follows much the same pattern It draws to a large extent on sources not readily accessible, and in the large section on archives almost entirely on material not previously published Moreover, the value of this assessment of developments in Britain during the period derives largely from the standing and experience not only of the contributors but of other librarians who have read and commented on different chapters. As a result, the report is an authoritative as well as a comprehensive and concise source of reference on numerous subjects, and the value of the information thus made accessible is enhanced by full references to each chapter Besides the section on archives already mentioned, there are six others between which there is some, but not excessive, overlapping These deal with national and academic libraries; special libraries; public libraries, library practice and library service; bibliography and documentary reproduction, and the library profession and professional organizations In the final section, separate chapters are now given to the Library Association, to the Association of Special Libraries and Information Bureaux and the International Federation for Documentation, and to international librarianship There are also new chapters on public relations and on the acquisition and use of periodicals in libraries

HISTORICAL RELATIONS OF SCIENCE AND TECHNOLOGY*

By Prof RUPERT HALL

Department of the History of Science and Technology, Imperial College of Science and Technology, University of London

IT is splendid that a great scientific and technological institution, such as the Imperial College of Science and Technology, has found room among the many facets of its expansion for a branch of historical investigation which has been, until lately, too often neglected I am happy also to acknowledge the great contributions to the study of the history of science which have come from our sister College (University College, London) over a period of more than forty years, and recently not only from the ancient universities in Britain but from the more newly founded ones also In Britain there is the nucleus at least of a proper professional body, so that the time for pleading the cause of history of science, and perhaps even for justifying its study, has already passed. Perhaps even in Britain, as already in the United States, the obstacles to the further increase in the number of university posts arise less from failure of demand than from insufficiency of supply

The history of technology, however, is in little better case now than the history of science was half a century ago—indeed, it is rather worse off since it cannot even to-day produce a scholarly eleven equal to that made up by Tannery, Sudhoff, Duhem, Heath and the rest, all at the wicket in the years before 1914 Yet societies have been formed, specialist journals have been founded, and within the walls of the great national museums the work of conservation and research goes steadily forward Here in Britain—with such leading figures as H W Dickinson and his successors—the Science Museum, South Kensington, has carried almost the whole burden of stimulating interest in the history of technology In France the Conservatoire Nationale des Arts et Métiers has been almost equally pre-eminent, and I think the situation has been much the same in Germany and Italy also, as indeed in the United States until very lately Despite spirited efforts to the contrary, this infant subject has not flourished in academic thickets, and in a measure less in Britain than elsewhere, perhaps because here (with the residua of the Industrial Revolution so thick on the ground around) the problems of conservation have seemed especially pressing and the tendency towards antiquarian enthusiasm peculiarly strong Just as Imperial College has its Queen's Tower, so Britain (I suspect) will never lack its last devoted tram-road and consecrated slag-heap The Flemings have Brueghel we have Lowry Not to push the point too hard, let me illuminate it in another way· on the Continent and in the United States small groups of scholars—altogether, admittedly, a very small band of medieval historians, archivists, palæographers and so on—have begun to take a constructive interest in the crucial, though slow, evolution of techniques which occurred in Europe during the Middle Ages It is perhaps strange that the pre-history of Western civilization is to be reconstructed from Lombard charters or the disputed meanings of words of obscure etymology, but so it is It would be pleasant to see more British scholars joining in this work, since it is necessarily in their province rather than that of the engineer or technologist The economic historians have already done a good deal, especially for modern times, but the particular alliance of interests and skills I am thinking of has scarcely yet occurred in Britain.

Perhaps I should try to explain why this kind of investigation into medieval technology (or one might as well say any technology which prevailed much before 1850) seems to me significant It might be condemned by applying to it any of those pejorative epithets which are attached to activities neither obviously utilitarian nor flattering to the speaker's particular tastes dull, esoteric, academic and so forth. Yet I think that it is broadly agreed that universities should provide something more than courses in survival, if life-jackets are to be the only wear and the only music that of the alarm-bell, then we should indeed end all frivolities That was the attitude of the medieval university But I presuppose a society which has leisure, surplus production, and free intellectual energy in such a society, it seems to me, at least the naive question, "How did things come to be as they are ?" is natural, widespread, and of general interest among men It is answered in a variety of ways, including the mythical, the poetic, and the religious scrupulous historical enquiry is that way which most closely resembles the scientific exploration of the natural world It is difference in logical structure, not (as is commonly supposed) difference in the methods used for the establishment of facts, which causes the expression of historical enquiry to be distinct from the expression of scientific enquiry, it is this (for example) that renders the discussion of historical 'laws' very different from that of scientific laws But this contrast is one which I need not pursue

Perhaps it is still worth emphasizing again that, if necessity is the mother of invention and altruism its maternal aunt, nevertheless the social conscience by itself has not proved a powerful spur to creative innovation. Pity may impel a man into medicine or inspire a humanitarian invention, but in general the creative faculty has been, so to speak, more highly introverted than extroverted Whatever may be the case now—and I do not really believe it to be different—certainly in the past the feelings in this respect of a literary investigator were not very different from those of a scientific research worker You may recall G H Hardy's observation that "A physiologist may indeed be glad to remember that his work will benefit mankind, but the motives which provide the force and inspiration for it are indistinguishable from those of a classical scholar or a mathematician" To which I would add, "or a historian" and I would further say that (setting aside the direct usefulness of applied science) Hardy's point can be extended to the appreciation of the work of physiologists and classical scholars, mathematicians and historians That is, the ultimate private intellectual satisfactions—disregarding altruism, which of course has no necessary nexus with the intellect at all—have profound common qualities, for the intellectual satisfaction of understanding something, of having intellectual command over something, is much the same whether the thing be differential equations, or the Romantic Movement, or Norman feudalism I take it to be in part the object of life (after the needs of survival have been met) to enlarge and enrich in a kind of Benthamite calculus the sum of intellectual satisfactions, and this has traditionally been considered a major function of education I have no wish to involve myself in a discussion of the philosophy of education, and so I shall simply assume that the traditional view is a just one, and if it is, then I think it follows that an interest in our past, in all its manifold aspects, is proper and deserving of encouragement

---

* Substance of the Inaugural Lecture delivered at the Imperial College of Science and Technology on November 19 (*Nature*, **196**, 319, 1962)

To be more specific, and to return to my point about medieval technology, its fascination is that of potentiality. It is possible—though I do not think this has yet been proved—that we can push back to a very early stage in the evolution of European society after the collapse of the Roman Empire (which was a Mediterranean civilization) those changes in both the quality and quantity of technological innovation that were to prove decisive notably, of course, the effective use of power It is a question of discerning whether a growth-curve is linear or exponential If early medieval technological development possessed only linear characteristics it is not terribly exciting If it possessed an exponential quality as the origin of the curve that was to shoot almost vertically upwards in the nineteenth century, then the technology of the early Middle Ages truly contains the historical mainspring of our own world, and the origin of the challenging events of our own time

The history of technology, like the history of science, is a study so multifarious in its demands that the proportion of scholarly to technical or scientific content is almost infinitely variable I have just mentioned an area where the scholarly skills are much in demand, but modern scientific and technical knowledge less so For in historical studies of the period before the past two centuries the 'language barrier' is as important as the 'mathematics barrier' in modern education Not to mention the most ancient languages in which the beginnings of all civilization are shrouded, nor the languages through which alone the oriental civilizations may be reached, nor Greek, there is the obstacle of Latin The Roman tongue, of course, was never nearly so important, intellectually speaking, as it became after Latin had ceased to be a living language The last major scientific contribution to be described in Latin which springs readily to mind is that of Karl Ernst von Baer, the discovery of the mammalian ovum, announced in 1827 There may be others of later date yet, and Latin certainly remains, to-day, a feeble vehicle of scholarly communication In spite of the immense volume of translation into English and other modern vernaculars, he who is ignorant of Latin must still see the thought of the past darkly and partially only the Babel of the past two hundred years is accessible to him This is the result of that eclipse of Latin as a universal language which the seventeenth century lamented and the growth of science, I fear, accelerated When the first *History of the Royal Society*, compiled by Thomas Sprat seven years after its foundation, was presented to Cardinal Leopold dei Medici in Florence, he complained (as did nearly all Continental scholars) because it was printed in English, to him a barbarous and unknown tongue But there was a ready retort to hand Leopold himself had permitted the *Saggi di Naturale Esperienze* of his own Accademia del Cimento to go abroad in Italian only a few months before As with us all, so with the French too they disliked the publication of the *Philosophical Transactions* in English, but they themselves, in their new Royal Academy of Science, adopted the vernacular

The story of the first phase in the battle between man and Nature, of course, is not recorded in language at all, the archæologists, with all the force of the scientific aids they can muster, must reconstruct it for us The story of the second phase is dominated linguistically by Latin, and operationally by the techniques of historical scholarship. The transition from the end of the second phase into the beginning of the third, long as two or three hundred years seem to us, has been brief on this historical time-scale Since we ourselves have but just now embarked as protagonists on phase three it is impossible to say how its history will be related We can only hope that the archæological methods used for the first phase may prove unnecessary, as we may guess that the scholarly ones used for the second phase will seem inappropriate For those terrifying statistics about the 90 per cent of all scientists being those now living, and so forth, will render that virtually certain

Historians of science and technology have so far been chiefly concerned with the second phase, and with the earlier part of the transition period signalized by the 'scientific revolution' of the seventeenth century The latter stages of this transition in the nineteenth century and the 'scientific revolution' in Sir Charles Snow's sense (introducing the third phase in the twentieth century) they have so far done little to explore It is easy to see why when we reflect that the kind of problem which has interested such historians into very recent times was actually determined about the end of the nineteenth and the opening of the present century I do not mean that there has not been great change in methods and ideas, and that in detail the modern academic conspectus of the history of science is not altogether different from that prevailing about 1890 but the overall shape is much the same, and indeed what we are doing now is built on what was done then, and that in turn was conditioned, I believe, by late-Victorian optimism and security, in the world of the solid atom, the steam-engine and (curiously enough) the horse

Although Wells and a few others foresaw the catastrophic potentialities latent in scientific and technological development, historians took a complacently progressive view Despite episodic retrogressions, sometimes lasting for centuries, the course of human history in the West seemed to show neither a Fall from a Golden Age (as men had once supposed), nor that stagnation which was attributed to the oriental empires, but, by and large, a steady increase in verifiable (or positive) knowledge, and constant enlargement of man's dominion over his environment What the seventeenth century had aspired to, through the mouth of Bacon and others, the late nineteenth century European had at last secured Not a few scientists of stature proclaimed that no more momentous discoveries were to be expected, historians on the whole concurred in regarding the views of their own times as the truths to which their predecessors had approximated It is needless to say that the same anticataclysmic attitude prevailed in the study of the history of technology the steam-turbine was simply a wonderfully more efficient Watt engine as the Watt engine in its time had been a wonderfully more efficient horse No one—or very few—who admired the work of Parsons and Edison and the rest regarded even the social forms of their own society as being under severe pressure

All that has been changed Speculation about what was progress and what was retrogression has been overwhelmed by the fact of change The secure world of the Victorian historian has disappeared He could tolerate—though I do not think he quite understood—the swiftness of scientific evolution in the seventeenth century because it could be accommodated the notions of Aristotle, Ptolemy and Galen were 'wrong', and the contradictory notions of Galileo, Copernicus and Harvey were 'right' With false truths dethroned, the enthronement of truth occurred once for all But it was impossible to repeat this—or at least it became very repugnant to repeat this—when it became a question of declaring that Galileo and Newton were wrong because Planck and Einstein were right For to admit this was to destroy the conception of truth's progressive revelation and the idea of complete developmental consistency

As my friend Tom Kuhn* has considered this matter of small jumps and big leaps in the history of ideas, I need not pursue it further I want to point out that there are now a few people—a very few—who are getting to grips with the start of the third phase, at least so far as pure science is concerned This means tackling, very directly, this problem of intellectual quantum-jumps on one hand and their immense cultural repercussions on the other For technology the beginning has still to be made, and should be made while change is still vivid in the minds of many men I think it important that the beginnings made, or to be made, should be expanded by many willing hands, for exactly the same reason that I believe political or social historians should interpret for us not only the fall of Troy or the wool-trade of medieval England, but also the events that middle-aged people like myself never properly understood and have already half-forgotten I hope something of that will be done in Imperial College, itself a product of the nascent third phase in the natural history of man

---

* Kuhn, T S , *The Structure of Scientific Revolutions* (Chicago, 1962)

But I must confess that, as an ingrained historian of the great transition, the story of this present scientific revolution is beyond me and I must leave it to younger men I have found some incursions into the first scientific revolution, that of the seventeenth century, sufficiently absorbing and complex I am not sure that on the purely intellectual plane (leaving aside the impact of science on technology and hence on society) there are not significant parallels between them For example, the Pascal syndrome—the reluctance to depart from an ordered, familiar world of the intellect to one that appears inchoate and strange—was apparent after Copernicus as after Einstein The shift from macrophysical modes of explanation to microphysical ones was a feature of the seventeenth century as of the twentieth The assertion that a new science demanded a new philosophy was common to both, and so on not least, there is to-day a revival of that appeal to a technological social conscience which was a marked feature of the seventeenth century I hope this evokes no absurd notion of 'history repeating itself'. nothing is further from my mind, what I mean to indicate is simply that the kind of intellectual gear-changing which was so constructive (and destructive!) three hundred years ago has analogies of form—not of content—with what has happened more recently Certainly—as I have already hinted—I believe the twentieth century revolution to be enormously helpful in understanding the seventeenth

In this earlier period my own chief interests have lain I had the advantage of setting to work under one of the finest English historians of that period, Sir George Clark, investigating the then quasi-mathematical science of ballistics and the interesting case of interaction between theory and craft that its early development presents I was seeking to vindicate neither the contention that the scientific revolution was the result of a drive for technical mastery, nor the opposed opinion that science is purely an intellectual game for scientists, the more beautiful as it is the more useless, this rivalry of argument was not my main concern Nevertheless, I learned something about this debate (to which I have again returned quite recently), which was a matter of warm concern until about twenty years ago, but has died down since Other issues have come to the forefront, rightly so, I think, because the attempt to assess the relations of science and technology in the seventeenth century on the basis of a still inadequate examination of the inward history of both the sciences and the techniques was necessarily premature

Historians are allowed, and indeed encouraged, to be a good deal less strict in their allegiance to one type of enquiry than scientists I have ranged fairly widely in the matters I have looked into here and there over the whole period from the early sixteenth to the early eighteenth century, with a fairly strong concentration on the English scientists associated with the first years of the Royal Society May I just say here how generous the officers of that venerable institution are to all who delve into their superb collections of books and manuscripts? My wife and I together have done a fair amount of work on the greatest of all that group, Isaac Newton, who is at last receiving the attention he deserves, rather than the praise which was much easier to give, and yet—if I may digress again—it is astonishing how little national pride we seem to have in the Englishmen who belong to all humanity except, apparently, to their fellow-countrymen

Perhaps I can again illustrate what all this is about by dwelling on Newtonian studies for a moment Into Laplace's time, ± 1800, Newton's was still a living influence much (one might say, because time moves faster now) as Bohr's is with us His printed works, but little more, were piously collected in one edition by Bishop Horsley a decent half-century or so after Newton's death—a Latin edition, of course Although the Bernoullis, and Leibniz, and Euler, not to say Laplace himself, had found some pretty weak spots in the Newtonian fabric, it was only the work of Young and Fresnel in optics that really upset a major piece of Newton's scientific work This fact won general recognition at a time when there was, for other reasons, a rather wide interest in the process by which the tremendous changes in thought between (say) Leonardo's day and Newton's had been brought about Some people, believing that early nineteenth-century science had lost this pristine vigour, sought to discover its origins Naturally, Newton was a focus of renewed, critical interest How had he been able to do so much? What was the history of his discoveries, and the nature of his thought? For whatever Wordsworth might say, Newton accompanied is much more interesting than Newton alone One result was the best of our early scientific biographies, Sir David Brewster's life of Newton—an important source-book even to-day

There, essentially, the matter rested until our own time Brewster, with Edleston, Rigaud, and De Morgan, had done much to make Newton a human and intelligible figure, neither a god nor a computor But they had scarcely scratched the surface of the mystery of intellectual power, of which Newton is a supreme and, as it happens, a well-documented example Brewster had been privileged to dip into that great mass of Newton's personal papers which had passed through the husband of his niece to the noble family of Portsmouth By a generous gift, the then Earl presented the scientific portion of the Portsmouth Collection to the University of Cambridge in 1872 A Cambridge mathematician and historian of mathematics, W W. Rouse Ball, was the first to make use of this open treasure in a little book that is still valuable, after that, I regret to say, it was almost totally neglected until some twenty-five years ago For long no writers on Newton attempted to go beyond his works and other printed sources Unfortunately, just as this position was about to change—and the event indeed stimulated the change—that part of the Portsmouth Collection which the family had retained was put up for sale by auction and dispersed That was in 1936 Only the energetic personal action of Lord Keynes prevented a complete tragedy by securing much for Newton's University The loss was the greater because the dispersed papers, though indeed containing little enough relating immediately to Newton's achievements in science and mathematics were capable of throwing much light on his mind and thought Fragments in Newton's hand now command high prices on the open market, and they will never again be reassembled for study

Meanwhile the intact portion of Newton's documentary legacy preserved at Cambridge has been subjected in the past few years to very intensive examination it has proved full of riches We can now know Newton's thoughts more intimately than any of his contemporaries knew them, and discern his personality with a clarity obscured by the rival partisanships of his friends and enemies We can see, as those could not for whom Newton was a miracle, more precisely what he owed to the giants on whose shoulders he stood, and how his own thought was interwoven with that of his age We can see, too, and perhaps most fascinating of all, a good deal of the development of Newton as a scientist from his very early twenties, as a student, to his last defences against the ghost of

Leibniz. There are still many gaps and problems, but it is possible to begin to reconstruct—as only study of copious and intimate manuscript material permits a historian to reconstruct—the movement of Newton's mind from his reading in Galileo, Descartes, Boyle and so on to the brilliant but partial truths of 1665–66 when he was "in the prime of his age for invention" and so to the full maturity of his major writings.

What is the historian after in dealing with such materials, both printed and manuscript? Certainly not just the human story of a life, fascinating though this may often prove to be. In the first place, he is after information; at this level he can share the satisfaction of a biologist in the discovery of a new species or that of a chemist in recognizing the intermediate steps in a reaction; the more information the more complete the picture, and the greater the verifiability of interpretation. But, above all, the historian of science and technology, like the research scientist, seeks for order or logic among the facts. He seeks to frame an intellectual scheme which is equivalent to, but less formal than, a theory in science. The object of such a scheme is to reduce apparent paradox, to show that the seemingly incompatible is compatible, and to relate the previously disparate. What did Newton mean by condemning hypotheses, when he himself made statements that he qualified as hypotheses? How could Newtonian space be a vacuum and yet action at a distance be a manifest absurdity? How did Newton come to be the author of both the *Principia* and the *Observations on the Prophecies of Daniel and John*? This is the kind of question that immediately suggests itself. Clearly the perfect scheme resolving these and other problems must be logically consistent, all-inclusive, and sequentially exact; it will remove out of the arbitrary realm and into the pattern of order what Newton pronounced here, the error he committed there. The essence of pattern, of course, is that it extends this side and that in space, or forwards and backwards in time; if it is true, as Karl Popper has taught, that explanation and prediction are logically equivalent, then perhaps I may add that one has a sense of historical understanding—the desideratum of historical enquiry—precisely when one achieves this Janus-like unity of the forward and backward view. That is, when we take our stand (say) at the year 1680 and see, on one hand, Newton's early thoughts as entailing his future achievements, and on the other these great achievements as no less accounted for by his early intellectual development.

No doubt history will never attain such perfection—not for Newton, nor for Galileo, nor Lavoisier, nor Darwin, to mention only a few of the giants intensively examined in recent times; and perhaps I seem to be expressing too personalist a view of history. I confess that to me it does seem that in the history of science and technology the history of men and their activities must figure largely; the anonymous idea yielded by a fictitious 'spirit of the age' is pretty much an excuse for inadequate research. One can usually find someone who pushed it. Of course, the man whose idea enthralls posterity may, like Mendel, have seemed dim to his contemporaries (though this is rare enough); but it is broadly true that to trace an idea, an experiment or a technique one must discover and comprehend the relevant individuals.

There is, however, another side to this coin. The fate of ideas and methods is no less interesting than their early evolution. Hence it is instructive to put the giants in their local settings: to discover the significance of Newton's philosophical naivety as Leibniz saw it, or how it was that Johann Bernoulli could accuse Newton of not knowing how to take a second differential. This is a type of case that is especially interesting just because one cannot simply say that men like Leibniz or Bernoulli were unable to adjust their conservative habits of thought to Newton's newer views—as we might at first feel inclined to say of Priestley and Cavendish with respect to Lavoisier—because it was rather the case that, to his opponents, it was Newton who was insufficiently *avant-garde*. This is the sort of situation which forces one to look particularly closely at both the historical and the logical relationships between ideas.

Gravitation furnishes but one example of the confrontation of an idea and a universally prevailing conviction: it would be easy to instance others. I should emphasize that in such confrontations the prevailing conviction is not just an opinion, however dignified—like one's preference, say, for neo-Georgian as against Bauhaus, or Bartok against Beethoven—but a psychological rock. Max Planck said that opponents of scientific innovation were never converted: they merely died. For Darwin, acknowledging his belief in evolution was like confessing a murder. So much of one's intellectual make-up, one's ego, can be involved in the falsehood of one idea, or the rectitude of another.

In a sense we may call this a social phenomenon, for it is the community through its educational system, its religion, and other more subtle influences that conditions the degree of flexibility or rigidity that governs a given area of scientific discussion, and moulds attitudes towards it. By 'community' I mean here essentially the scientific community, though one would sometimes need to take the word in the widest sense, too. So that if one side of the historical coin is the genetic evolution of scientific ideas, as I have already mentioned, this other side involves the sounding and surveying of the scientific community to see what sort of a culture it is in which the ferment of new ideas works. Perhaps I may just mention the activity which we are pursuing here at this level, namely, the editing of the correspondence of Henry Oldenburg, the active secretary of the Royal Society from its origins in 1660 until his death in 1677. Oldenburg was in touch with an immensely wide range of correspondents from the most sophisticated scientists like Newton or Malpighi to bucolic doctors and rural deans. In this great collection of letters one can see not only how science lived from day to day and year to year, but also who the men were by whose efforts science lived. Here, too, as in the study of such a giant as Newton, through his manuscripts, it seems to me that the adequacy of the whole picture depends on the sharpness of microscopic images. We hope that when our work on Oldenburg is finished we shall have done something to increase the resolution of our picture of the early Royal Society in action, of the relations between British and Continental science, and of the scientific movement in Britain. But I do not wish to dwell on this so much as to direct attention to the even greater relevance of this kind of treatment to the early progress of technology.

It is easy to overlook the smallness of the scientific community in the past. In seventeenth-century England the average number of men elected in each year to the College of Physicians was five or six; one more physician on the average took a degree abroad each year. Thus the number of men living in and about London with a keen, active interest in the medical sciences can never have been much more than a score, a number so small that each could be intimately acquainted with the others. It is doubtful whether, in Newton's day, the number of competent mathematicians in the whole country was so large as that, and certainly there were not half as many capable astronomers. I am conscious of the relatively large numbers of amateurs and of those who (like opticians or distillers) practised empirical science in a commercial way: yet, in fact, the average number of elections to the Royal Society before 1700 (neglecting the 115 original Fellows) was only about ten, and so on. That means that the impact of any question of abstract science on a human brain was exceptionally infrequent—it could only happen to, say, one individual in a hundred thousand. It is therefore easy for the historian to know this tiny fraction of the population quite intimately—

better than one can know, say, the composition of the contemporary House of Commons But in the history of technology the situation is very different, the proportion of human beings who have been very well acquainted with hand-mills and ploughs and textile- and horse-gear has always been very large indeed, until the last century or so in the West Very few of these ever effected the slightest variation in any technique but the potentiality for effecting a variation was virtually universal It is only when the use of relatively uncommon machines or techniques is introduced that the potentiality for innovation becomes restricted Moreover, we have not much reason to believe that in the early stages, at any rate, learning or literacy had anything to do with it, on the contrary, it seems likely that virtually all the basic techniques of civilization up to a couple of hundred years ago were the work of men as uneducated as they are anonymous. Moreover, while it is one thing to examine, say, the reaction of a small group of medical men to the notion of the blood's circulation, it is quite a different thing to investigate the attitude of a whole population to a new plough, or a new military technique, on which, nevertheless, its economic or political survival may depend Hence, to choose yet another example from our own continent, it is often difficult to determine whether delay in change is due to ignorance or inertia Were the Saxons defeated at Hastings because they just had no knowledge of the new continental ways of fighting, or because they had obstinately refused to practise them ? Without wishing to be utilitarian, it is obvious that discussion of this kind of issue is by no means lacking in contemporary relevance we certainly do not know much about the factors that cause a society either to make good use of its technical potential or to neglect it History cannot solve such problems as these, but it can make us better informed

I shall conclude with a question "What is the role of historical studies in a scientific and technological college ?" The Robbins Report expresses the opinion that such colleges should develop "related subjects such as social studies, operational research and statistics on a significant scale, and languages will be needed at least as auxiliary subjects" The Report does not firmly pronounce on the much-debated question of recent years, whether or not steps should be taken to break down the segregation between arts and sciences that is so typical of first-degree work in British universities as it is untypical in the United States Nevertheless, its view is warmly in favour of greater educational breadth than we now have, and it specifically mentions history of science as an appropriate combining subject Again, I avoid deliberately opening that issue, though perhaps I may state my personal view that early specialization either way is indeed productive of intellectual sterility I remember a good many natural science students from Cambridge days who found history and philosophy of science a relief from memory-loading, and for whom discussion of ideas was a revolutionary experience The sheer expansion of numbers now approved will itself enforce a change in methods of teaching—in the schools as well as in the colleges—and a slowing down of the tempo The alpha-plus student, given books, can virtually teach himself or herself any subject, large numbers will demand the meticulously worked-out, highly-organized and very thorough course-work that is commonplace in the United States but not in Britain—at any rate, it was not a few years ago No one dare predict, but it is on the cards that when this happens the pair of contradictory arguments one has so often heard—according to which students of science (1) acquire culture by osmosis and (2) have no time for anything but science—will disappear at the same moment

In any event, what may happen here in the future will be governed by future discussion Will Imperial College, like the Massachusetts Institute of Technology, develop its department of humanities ? Experience in the United States has shown that attempts to force culture on those who are straightforwardly eager to secure a professional qualification and embark on practice are not very successful For my part, knowing my own limitations, I make no pretence of being a cultural physician, and I boast no desire to serve as the spoon that administers some unwelcome dose As for bridge-building, I would rather leave that to the civil engineers On the other hand, I believe history of science, and history of technology and philosophy, too, have a large role waiting for them in the more liberal scheme of British education that I hope will come, and at all levels, in schools, in undergraduate work, and in postgraduate study History, whether of science or of industry, seems to me like the history of politics, of society or of literature, part of our common culture Newton, Tolstoy, Renoir, Beethoven, Gauss, whatever one's profession or one's tastes, one should not greet any one of these names with a blank stare of vacuity Ideally, history of science at the university should find its natural and leading place in a general pattern of education that is bifocal rather than one-eyed, as one among a number of elective subjects for study I think the Americans have something there At the present time, however, it will be the chief task of the new Department in Imperial College to reinforce others in training those who, in various capacities, can promote this liberalization in education. Many here, as everyone knows, have long been striving towards the same end May I say that we look forward to close co-operation ? Wherever we can play a part in the life and activities of the College that is not directly devoted to pre-stressed concrete, catalytic crackers, or electron multipliers, I hope we may be able to do so But, like children, we would rather be heard as well as seen, for, in the immortal words of Archdeacon Spooner "It's beery work preaching to empty wenches"

SCIENTIFIC, TECHNOLOGICAL AND TECHNICAL MANPOWER*

By Sir WILLIS JACKSON, F.R.S.

Department of Electrical Engineering, Imperial College of Science and Technology, University of London

IN his recent presidential address ("Investment in Man") to the British Association for the Advancement of Science (*Nature*, 199, 877, 1963), Sir Eric Ashby, following Sir John Cockroft's preceding presidential address on "Investment in Science", said "The pre-requisites for investment in science are, first, scientists, and, second, a public opinion sufficiently well-informed and enlightened to give financial support to scientists Both these pre-requisites are acquired through education To invest in science you must first invest in man"

I wish to develop a variation or extension of this theme It is that, generally speaking, the impact of science on the life of the community, and in particular on its economy, is not a direct one but comes from the technological exploitation of its results Unless, therefore, we are strong in our technology, which requires that this need is recognized throughout the community, there is a danger that the economy may fail to provide for expanded scientific pursuit the increasingly expensive facilities and resources which this pursuit nowadays demands

---

* Substance of the tenth Fawley Lecture delivered in the University of Southampton on November 21

A recent report by a committee of the Institute of Physics and the Physical Society entitled "Problems facing the University Physics Departments" details in an extremely convincing manner the needs of these departments if they are to meet their increasing teaching obligations satisfactorily and to remain in the forefront of international research in physics

I have no wish to argue against the claims put forward in this report in relation to what is good for physics Indeed, I am very sympathetically inclined towards them because, as an electrical engineer, I have good reason to be conscious of, and grateful for, the periodic stimulation of progress in my branch of technology which has come from fundamental work and discovery in physics Moreover, I am in no doubt that outstanding physicists, and those who show promise of becoming such, must be free to follow the directions which their scientific curiosity dictates without any necessary direct concern for the possible technological significance of the results of their work This freedom has been a well-safeguarded characteristic of university science in Britain, and I hope it will remain so It can be tampered with only at risk to the seed-bed from which important contributions to the future progress of technology will spring It follows also that these outstanding scientists must, so far as is practicable, be provided with the most up-to-date tools of investigation, and with adequate supporting assistance and technical staff, if they individually—and through them the country—are to remain in the forefront of scientific endeavour and achievement

But physics is only one branch of science Other branches could, and some already have, put forward similar claims for much expanded support, and I, as a comparative outsider, cannot but be impressed by the pertinency of such remarks as those of the Editor of the *Times Educational Supplement* who commented on the aforementioned report "The money that is just enough to make a significant difference to physical research would finance the whole of the national effort in biology" To which I am inclined to add—may not biology bear the same relationship to the next major technology as physics does to several present ones, and may not our neglect of the human sciences be the most serious unbalance of all ?

Acceptance of the unpredictability inherent in scientific pursuit, and of the necessity to maintain the freedom of enquiry which has been the traditional prerogative of basic science, affords no escape from such questions as Have we yet devised an effective means of making overall assessments of, and judgments on, the claims of the various branches of pure basic science ?*, Have we yet established satisfactory arrangements for the distribution of the available funds for this basic work ?, Are we anywhere near knowing on what criteria to decide how much of our national resources must be made available for its pursuit ?

It is not my intention here to seek answers to these questions They are matched, of course, by a number of related questions concerned with objective basic research* and applied research*, questions which are perhaps more difficult to resolve So far, decisions in these fields have been taken within the respective spheres of the establishment of the Government and public services and of industry, without significant co-ordination in the national sense It will not be easy to find, and many will no doubt argue that it is neither necessary nor desirable to find, a more effective alternative way of dealing with these problems

Nevertheless, the hoped-for devotion of increasing funds from central sources to research would seem to lead inevitably to a need for a clearer concept and formulation of national scientific policy, and for more co-ordinated means for its implementation

My justification for raising these issues is to make the point that the moneys available for devotion to research *for future purposes*, either from the central funds of Government or from the resources of individual industrial concerns, are dependent on the effectiveness with which the results of research *already completed* are translated into goods which can be sold internationally against increasingly severe competition

This raises a whole range of further questions concerning the factors which affect productivity and economic growth, now under consideration by the National Economic Development Council Not all these factors are, of course of a scientific or technical character, as these terms are normally understood—indeed, those which are most difficult to understand and resolve are certainly not But they seem to me to lead equally inevitably to the need for a clearer concept of scientific policy as an integral part of economic policy As put by C E Carter[1] "If we do not have an economic policy about the distribution of scientific resources, we are unlikely to have any policy at all A starting point for scientific policy is the examination of what we know about the pattern of exports ten to twenty years ahead At many points there will be a temptation to suppose that the problem of the distribution of scientific effort is too difficult, complex and vague to be solved Yet a few tentative moves towards rationality may be better than leaving the disposal of a valuable resource to random and undirected influences".

Since research can have military, social and political, as well as economic, consequences, scientific policy is becoming more and more an integral part of national, if not of international, policy in the widest sense In varying degrees the scientist, technologist, economist, sociologist, employer, Trade Union official, legislator and political leader all find themselves involved increasingly in the consideration of—if not in the taking of decisions on—the role which scientific research and technological development must occupy in national affairs, the resources which should be devoted to them, and how these resources should be allocated and balanced in the light of overall national policy

All this leads to the need for a clearer concept of manpower policy involving, for my present purposes, assessments and judgments on the likely future requirements of the community for the varied kinds of scientific, technological and technical manpower, and on the means by which these requirements are to be satisfied

I do not pretend that there is anything new or novel about the preceding Nor do I wish to appear unaware or inappreciative of the prolonged and careful attention which has been given to different aspects of the complex and difficult problems I have touched on by the responsible authorities, and by committees specially appointed by them for this purpose But it is surely right to say that we, and most, if not all, other countries, are still at a very early stage of our systematic consideration of the interrelationships between these various facets of national policy We do not yet know how to plan and implement deliberate changes in one sphere in appropriate scale and time relative to changes in others, so that the evolving needs of the overall situation—so far as we can reasonably hope to foresee them—can be most satisfactorily met Much hard thinking, study and experiment will be required before the largely empirical procedures which have been adopted so far can be much improved on Each country will no doubt evolve its own characteristic approach depending on its national traditions, attitudes, resources, forms of existing institutions, etc This diversity affords a fascinating starting point and opportunity for international co-operation in the resolution of problems which become increasingly matters of joint concern

---

* The Zuckerman Committee on the Management and Control of Research and Development defined these categories of research as follows Pure basic, research carried out for the sole purpose of increasing scientific knowledge, Objective basic, research stimulated primarily by some practical need in a field of potential application, Applied, research differing from objective basic in which speed and the interests of the ultimate user come prominently into the picture

I must now seek to justify this extremely general, perhaps rather diffuse and impractical, introduction by relating to it some problems of scientific, technological and technical manpower which seem to me to give cause for concern The periodic reports of the Committee on Scientific Manpower published over the past seventeen years or so have made a very important contribution to clarifying the national situation in this respect by aggregating the anticipated future demands of industry, the Government and public services, education, etc , for scientists and technologists of various kinds, and by relating these estimates to the expected supply from the universities, colleges of technology, and other sources These reports have assisted the University Grants Committee and the Ministry of Education in the formulation of their plans for a considerable improvement and expansion in the facilities for scientific and technological education within the universities and the colleges of technology respectively, and done much to stimulate the marked change in the pattern of sixth-form work within the schools which has occurred during the post-war period The 1963 report[2] probably gives a better quantitative picture of the distribution of our existing scientists and technologists, and of the expected supply and anticipated demand over the next few years, than is available in any other country

It is evident, however, that we are a long way from knowing how to make an assessment of future *needs* for scientific, technological and technical manpower based on a forecast of the pattern of desirable national development and economic growth Taken literally, this may be asking for the impossible, and in any event such a pattern is only in the early stages of conception by the National Economic Development Council Certainly, as outlined particularly in its 1961 report, the Committee on Scientific Manpower has tried to make such projections, but it has necessarily had to base much of its assessments of likely *demand* on the opinions of individual employing organizations Some of these will not have been well situated, because of a dearth of suitably qualified and informed opinion within them, to judge their future need for scientific and technological manpower and to conceive how to make effective use of it The demand of these organizations is, therefore, unlikely to have reflected an adequate appreciation of the kinds of change which are now possible, and necessary, but which only qualified staff can formulate and carry to successful completion On the other hand, there are no doubt organizations which, though recognizing an expanding need for qualified manpower, may not have been able to foresee the financial possibility of initiating and sustaining desirable programmes of new development

In the second place, we do not yet know how, within a democratic community, to ensure a pattern of *supply* which is commensurate with that of anticipated demand—or need—at the time when this demand requires to be satisfied What we have sought to achieve is an adequate overall supply, subdivided into broad categories and characterized by sufficient flexibility and adaptability to meet unpredicted, or unpredictable, changes in the national situation Nevertheless, the 1963 report reveals a number of discrepancies which illustrate the kinds of problem for which we must surely seek more effective solutions

Thus the report states

"The information now available to us from the 1961 Census enquiry, together with the results of the 1962 Manpower Survey and the employers' estimates of requirements, suggests that we are still some way from a satisfactory balance of supply and demand, particularly as regards technologists

"The relation between supply and demand differs greatly from one discipline to another This has always been so, but in the conditions of extreme overall shortage which prevailed after the war, the first objective was to get near to an adequate total supply of scientific manpower As we approach the first objective, analysis by discipline becomes increasingly important "

In respect of some of these disciplines, the most notable discrepancy on the science side is in mathematics, where—"it seems likely we shall be short of nearly 1,500 mathematicians in 1965", while in physics—"the number of new physicists who will become available by 1965 would suffice to meet the requirements forecast by employers in the sectors covered by the Survey only if there were little or no growth in the employment of such men in other fields" On the technology side, although the number of students qualifying annually in electrical engineering has risen from 1,284 in 1960 to an estimated figure of 1,830 in 1964—"there will still be vacancies for about 4,000 in 1965, even when no allowance is made for the replacement of wastage or for possible growth in sectors not covered by the Survey" The position in mechanical engineering is particularly disturbing The number of students qualifying has fallen progressively over the same period, from 4,574 in 1960 to an estimated 3,385 in 1964 Although the report does not give a figure for the likely 1965 shortfall in this subject, the trend in output is clearly quite inconsistent with the central position which mechanical engineering occupies within technology as a whole

These figures provide one piece of evidence of the unattractiveness of technology relative to science to the scientifically minded products of our schools Much further evidence is given in the recently published booklet *Technology and the Sixth-Form Boy*[3], and it may be of interest to supplement this by the data of Tables 1 and 2 The former gives comparative figures for new entrants to the science and technology faculties of the universities over the period 1954–1962[4], and the latter the 'home' student applications per place in the several university faculties over the period 1960–1962[5]

Table 1 FULL-TIME STUDENTS ENTERING THE UNIVERSITIES OF GREAT BRITAIN FOR THE FIRST TIME

Academic year	Science	Technology	Total
1954–55	4,880	3,199	8,079
1955–56	5,400	3,341	8,741
1956–57	6,079	3,835	9,914
1957–58	6,644	4,269	10,913
1958–59	6,801	4,590	11,391
1959–60	7,043	4,491	11,534
1960–61	7,787	4,446	12,233
1961–62	8,519	5,064	13,583
Oct 1962 (provisional)	8,829	5,103	13 932

Table 2 HOME STUDENT APPLICATIONS PER PLACE IN VARIOUS UNIVERSITY FACULTIES

	1960	1961	1962
Arts and Social Science	6	7	8 5+
Science	7–	7 5+	8 5
Technology	4 5	4 5	5+
Medicine and Dentistry	6	8+	11 5
Overall	6	7	8+

The figures in Table 2 were calculated by Prof J T Allanson, from the annual returns of the Committee of Vice-Chancellors and Principals They embrace multiple applications and also students who fail to qualify for entry, and there may well be differences between faculties in these respects Nevertheless, the difference in respect of technology seems too large not to be significant

In respect of numbers, the technology situation is relieved somewhat by the gratifying growth in entrants to diploma in technology courses, as shown in Table 3 Nevertheless, even when the output from these courses, and from other, mainly part-time technical college, courses which satisfy the examination requirements of the professional institutions, is added to that from the universities, the position relative to science is disturbing This is revealed by the Scientific Manpower Committee data of Table 4

But there is a second discrepancy—that between the performance in the General Certificate of Education, Advanced Level, and related examinations of the entrants to full-time courses in science and technology In supplementation of other published evidence on this point[3]

Table 3 NEW ENTRANTS TO DIPLOMA IN TECHNOLOGY COURSES 1959–63

	1959	1960	1961	1962	1963
Engineering	1,108	1,199	1,211	1,517	1,718
Other technologies	450	570	558	843	979
	1,558	1,769	1,769	2,360	2,697

Table 4 ESTIMATED NUMBER OF STUDENTS QUALIFYING* ANNUALLY 1960–1964

	1960	1961	1962	1963	1964 forecast
Science	7,343	7,569	8,144	8,870	9,645
Technology (total)	9,783	9,916	9,907	9,800	9,910
(Mechanical engineering)	(4,574)	(4,443)	(3,939)	(3,635)	(3,385)

* By degree, diploma in technology and other examinations satisfying the requirements of the appropriate professional Institutions

Table 5 gives an analysis of the subject of undergraduate study chosen by the top thirty candidates in the Imperial College Entrance Scholarship examinations over the period 1954–1963 It will be seen that the ratio of engineers to scientists is about 1 to 3 5 and this has been getting worse, and of electrical and mechanical engineers to physicists 1 to 7 5 and 1 to 9 5, respectively Table 6 gives the mean percentage in the G C E "A" level examinations of all the undergraduate freshmen in physics and electrical engineering over the period 1956–1962

Table 5 ANALYSIS OF THE TOP 30 CANDIDATES IN THE IMPERIAL COLLEGE ENTRANCE SCHOLARSHIP EXAMINATIONS 1954–63

	Subject of later undergraduate study								
Yr	Maths	Physics	Chemistry	Elec Eng	Mech Eng	Civil Eng	Chem Eng	Aero Eng	Metallurgy
1963	6	14	4	–	2	–	2	–	2
1962	5	11	7	4	2	–	–	1	–
1961	9	14	2	1	–	1	–	3	–
1960	5	7	9	2	4	1	1	1	–

Table 6 MEAN PERCENTAGE IN THE GENERAL CERTIFICATE OF EDUCATION, ADVANCED LEVEL EXAMINATIONS OF THE UNDERGRADUATE FRESHMEN IN PHYSICS AND ELECTRICAL ENGINEERING AT IMPERIAL COLLEGE 1956–62

Session	Physics	Electrical engineering
1962–63	68 1	64 2
1961–62	68 5	63 5
1960–61	69 1	62 8
1959–60	68 8	63 0
1958–59	70 3	61 6
1957–58	69 1	65 9
1956–57	68 1	61 9
Overall average	68 8	63 3

I regard this second discrepancy as much the more serious, notwithstanding that I have no great confidence in examinations as a basis for predicting quality in later life Certainly I have no evidence of a close correlation between quality as judged by examination performance at the age of eighteen and quality as revealed later among practising technologists The successful pursuit of technology demands characteristics of mind and of personality which do not lend themselves to assessment by examination, and a quite different environment from that of school and university—and of the research laboratory—for their full development and refinement Nevertheless, if, as many people keep saying and as I believe, our national weakness, taken overall, lies not in our research but in our relative inability to translate its results into technological achievement, it seems to me that we cannot be content with a lower quality of entrant at the technological starting point, as judged by whatever criteria are generally applied at that stage of the educational process

What now are the essential differences between science and technology ? According to a recent definition[6], science is knowledge obtained by observation, by experiment and by subsequent deduction. Natural science is the investigation of the nature and properties of natural bodies and natural phenomena The object of the scientist is the determination of general laws and the deduction of principles from the effects which are observed Technology, on the other hand, is defined[7] as the science of the industrial arts, and the technologist is therefore one who applies scientific principles and imagination to the conception and creation of useful material products required by the community

J T Allanson[5] has drawn the distinction in the words "Just as the painter is judged by his paintings and not by his writings on æsthetics, so the engineer is finally judged by what he makes The making involves him in the social sciences and in relations with other human beings It is not possible for a good engineer to be a 'back-room boy', nor can he believe in that curious battle between the 'two cultures' invented by Sir Charles Snow He must make an engineering unity of the physical and social sciences by the kind of intellectual and moral effort supposedly characteristic of the man who reads 'Greats' With this he must integrate imagination and personal drive, for he is not a scholar but a doer, and the more visionary and far-reaching his ideas the greater must be his struggle to achieve them against the conservatism of the orthodox".

Technology spreads over applied research, development, design, manufacture, and operation, and the technologist may be found within any of these functional activities Scientists, on the other hand—until they also are more correctly described as technologists—are concentrated within the fields of basic and applied research, and of the initiating stages of development. The clear-cut area of demarcation is, therefore, design

In relation to mechanical engineering (and most design has strong mechanical associations) the recently published report of the Feilden Committee[8] defines design as—"the use of scientific principles, technical information and imagination in the definition of a mechanical structure, machine or system to perform pre-specified functions with the maximum economy and efficiency"

In the past, and indeed in the present, the majority of the country's designers have not been educated in degree or equivalent full-time courses, but through long practical experience and part-time courses, and often no courses at all The best of these men were, or are, outstanding in spite of the deficiencies of their educational preparation, and we have much reason to be deeply grateful to them for their inventiveness and their native engineering intuition and competence But this method of preparation will no longer suffice The origins of invention and the foundations of creative design are moving back more and more into science, and demand an educational discipline as prolonged and as searching as that required by the scientist But the discipline involves a different emphasis, for it is an art as well as a science, leads into a different environment with different objectives; and requires a preliminary training within this environment to provide contacts with the practices, the organization and the people necessary for the translation of design into production and operation It raises issues of economics and human relations from which the scientist is largely protected, and increasingly so as it moves beyond design into production, sales, operation and management Technology is not only an exercise in the application of science, but an even more difficult one in the motivation of people towards defined material objectives[9]

From now on, more and more of the equivalents of the men I have mentioned will remain at school until they are eighteen years of age, and will enter full-time university or college courses It is of great national importance that they shall not be lost to technology, for we need many more, not fewer, of them Not all design is concerned with major projects, of course, and even with these much of it is related to small components of the whole But this is no different from scientific research (except that, in the latter, study of the components leads more readily to publications of no great importance which fewer and fewer have time to read), and the sheer professional competence required is certainly of no lower order in one than in the other

I have heard it argued that they will not necessarily be lost to technology if their university education is on the science side, and indeed that a first degree in science is the best preparation for participation in the technology of the future It will be evident from what I have already said that I am in no doubt as to the necessity for strengthening the scientific foundations of technological education, but I have also expressed my conviction that this education involves different emphases than are to be found, or could reasonably or rightly be expected to be found, in pure science courses I am well aware of the substantial participation of physicists in the electronic branches of electrical engineering, but there is no evidence, and not much likelihood, of a corresponding help to mechanical engineering, for example, from this source It seems to me that the argument can be misleading both in respect of strengthening the country's technology at its weakest points, and of the best interests of the careers of the persons concerned—unless, that is, they are prepared to embark on appropriate technological study at the postgraduate stage At present most of those graduates of the university science schools who join industry enter its research departments In this sphere of industrial activity their contributions are invaluable, but, as a generalization, the environments in which research, and indeed development, are conducted, do not by themselves afford the kinds of basic training and experience which are essential to the successful pursuit of the design, production, operational and managerial aspects of technological activity.

Though at the recruitment stage the science graduate may not, of course, be interested in these activities, he may well become so later as his inclinations change, or should his creative abilities in research and his career prospects in it fail to mature It then becomes difficult, and the more so the older he gets, for him to move into other spheres of industrial or related employment, notwithstanding that these spheres may be much in need of men of his intellectual powers Indeed, an extremely sad feature of the research and development departments of industry and of Government departments, seen in both individual and national terms, is the number of men of considerable ability and promise who have become locked up in these environments from an early stage in their careers The immobility of qualified manpower between the interrelated spheres of scientific and technological life is an outstanding defect of our national situation Among those who pay the highest price individually, and are the greatest loss to the strengthening of our technology, are the able men who discover that they are not, as they had hoped to be, outstanding research scientists

I must not pretend that the employment situation for technologists is free from discouragements, knowledge of which has penetrated to levels which affect the choices of young people Those sectors of industry which are most in need of technological stimulation are too often unwilling to establish the conditions of employment for qualified manpower which are a prerequisite for it Other sectors, where this is not the case, are often said to cause frustration and discouragement to their qualified recruits during the necessary phase of preliminary training, to afford inadequate status and salary to their more senior technologists, and inadequate opportunity for those who wish to rise to the top levels of management I do not doubt that there is justification for these criticisms, though I have known them to be much distorted Where they are justified, however, they demand the most urgent attention and correction But it is not difficult to pin-point a number of other, quite different, reasons why we are failing to produce a public image of technology which is consistent with its national importance, and to attract a larger proportion of the most promising of our scientifically minded schoolboys to its pursuit

First, there is the widespread lack of acquaintance with technology among headmasters and their staff colleagues While this may not create, it is certainly not calculated to remove, the serious misconceptions present among schoolboys referred to in *Technology and the Sixth Form Boy*. In paraphrase, some of these are: that engineering studies are all right for boys who are good with their hands, but not for those who are good with their heads, that all the new ideas in engineering come from the scientist, that all the really difficult problems of engineering are solved by the scientist, and that the rest is just straight engineering In more recent comments, at a British Association meeting discussion on this Oxford University enquiry, W. D Hutchings remarked that the main single factor leading to the narrow and often naïve approach of many boys to their future careers is the intense and premature specialization to which they are subjected, causing the best boys to be channelled into the subjects in which they have been most successful at school, with the glamour and prestige of research as a prime incentive.

I find it quite understandable that the science departments of the universities do not discourage the latter trend But what I do not understand is the impression given by many staff members of these departments that they regard the process of translation of the results of scientific work into technological achievement as a markedly lower-grade activity than their own, and what I regret is their stimulation of the belief, which extends well beyond those students who are likely to be well suited to it, that research is the only valuable outcome of a scientifically based education

The situation is not improved by the otherwise quite excellent science programmes of sound and television broadcasting These not infrequently, but no doubt unconsciously, credit scientists with much that is essentially achievement in technology, while other programmes do little to correct the widespread misunderstanding that engineering and a pair of overalls are synonymous—though at a very important, but non-professional, level they undoubtedly are

The university engineering schools have themselves done a dis-service to their cause by differentiating too early between the several branches of engineering, and fostering the concept of narrowness and rigidity in their undergraduate courses. In fact, there are now strong movements, notably within the plans of the new universities, towards more general courses in engineering science This involves, however, an increasing participation in postgraduate courses of study in more specialized fields, and a willingness on the part of employers to sponsor the return of selected graduates for this purpose

The professional engineering institutions have also contributed by retarding the emergence in the public, and indeed in the Governmental mind, of a clear concept of technology and of the position which the profession of engineering occupies within it No doubt each of the many such institutions has a distinctive service to perform in catering for the technical interests of a different branch of the profession, but only since the formation about a year ago of the Engineering Institutions' Joint Council, representative of thirteen specialist institutions, has there been a deliberate approach to the formulation of an overall common policy on such questions as education and training and professional recognition It is one of my hopes that the corporate members of all of them will soon come to be known as 'chartered engineers', and that steps will be taken to ensure that the meaning and significance of this common title is clearly and widely understood

Finally, the Civil Service is also not free from responsibility in so far as the majority of the professional engineers whom it employs form part of the so-called works group of professional classes, a term which suggests that their status is lower—as their career prospects undoubtedly are—relative to the members of the Scientific Civil Service

This complex situation will not be easily resolved However, the considerable attention which the subject has received in reports, speeches and the Press during recent months, and to which the Duke of Edinburgh has made several notable contributions[10], is gratifying evidence of a growing recognition of the need to do so. The next step must be a determination by each of the sectors of the community which I have mentioned to make its appropriate contribution towards this resolution

It seems to me that the most crucial people for this purpose are the scientists, and particularly the outstanding scientists, and, if for no other reason, in the long-term interests of science I have not only in mind the contributions, of which many examples can be cited, which new tools of investigation resulting from technological progress can make to the further progress of science, but also the relationship which must exist between the scale on which new scientific work can be supported and the growth of the national economy, and the dependence of the latter on the economic consequences of the technological exploitation of what is already known in science I would, therefore, ask the outstanding scientists, to whom and through whom the opportunity to pursue new ideas is of outstanding importance, to show a greater readiness to recognize publicly that the speedy translation of the results of research through development, design and manufacture into efficient, reliable and economic pieces of equipment is an activity which can make intellectual demands no less severe, if different from their own; and that these activities justify a public prestige commensurate with the one which their own activities enjoy It is probable that such assertions as these will be really believed by schoolmasters, parents and the best boys only if they are made by outstanding scientists—and one must hope first that the outstanding scientists themselves really believe them

I have already mentioned a number of aspects of the employment situation for technologists which require urgent attention, but there is another which leads me into another category of manpower My experiences and observations of recent years have left me in no doubt that some, if not much, of the work being carried out by professionally qualified people could, with appropriate replanning and the fuller use of modern techniques, perfectly well be performed by persons of lower academic qualifications The process of devolution is, of course, a continuous ,one in any progressive situation It is a process which tends to increase, not decrease, the need for highly qualified people, through stepping up the standard of the overall activity. But it demands for its progression the availability of others, themselves well educated and trained, though to a different level or levels, on whom the work can be devolved

The effects and the demands of technical change in industry and elsewhere are emphasizing the growing significance of the category of manpower lying between the technologist and the craftsman and operative—a category which, in engineering, is coming to be described collectively as that of the technician engineer Regrettably, in our concern for our shortage of scientists and technologists, we have been inclined to overlook somewhat the importance of their supporting contribution and their needs in education and training, so much so that our greater present shortage may well be at this level So far the members of this category have come mainly through promotion from the ranks of craftsmen and operatives, or are men who, having aspired to professional status, have failed to achieve it All too few of the former have pursued their technical studies to a standard adequate for the evolving requirements of their new activities and responsibilities, or have received any specific training in preparation for them This will no longer suffice—if, indeed, it has sufficed so far—to deal with the rapidly increasing technical complexity of engineering equipment and systems, and of the problems involved in their manufacture and operation This does not mean that all the functions performed by the technician engineer call for high qualification in the academic sense, for they vary considerably in their technical demands What it does mean is that more specific steps must be taken in both education and training to ensure adequate preparation for the duties to be performed

The Ministry of Education made an extremely important contribution towards this end in its formulation of a new pattern of technical education in a White Paper issued in 1961 This pattern is now taking shape in technical college courses, with the assistance of the City and Guilds of London Institute, but much remains to be done by many employers in respect of their willingness to afford day-release facilities to their young recruits and to provide associated training of adequate standard within their own concerns

About a year ago the Committee on Scientific Manpower initiated exploratory steps in preparation for a national statistical survey on technicians These are taking the form of sample enquiries involving a small number of firms in selected industries Their purpose is to ascertain the relationships which exist within them between technicians—if so-called—and other categories of personnel employed; the kinds of duties with which the technician is identified, the nature of the responsibilities which these duties involve, and the status attaching to them, the evolving changes in the character of technician employment, the type of preparation in education and training which the present technicians have received, and the modifications to these which are thought to be necessary for future purposes The objectives to be aimed at must be, of course, not merely to state the present position but, so far as practicable, to assess qualitatively and quantitatively the aggregate needs that lie ahead so that the earliest possible preparation can be made for meeting them.

This is a difficult and long-term exercise, but it is obvious that the assessment is integral with the one for scientific and technological manpower—indeed, that neither can be made reliably without the other The pity is that we are only at the beginning of an attempt to interrelate them

In conclusion, I wish to make two points, both of which have no doubt been made many times in different ways

The first is that those young people who choose, or are persuaded, to prepare themselves for careers in science and technology must, as an integral part of their education, have their minds opened to the sociological implications and consequences of scientific and technological progress, and of their special responsibilities towards them, and no less important, that those who choose one or other section of the faculties of arts must be helped to extend their knowledge and understanding of the history, the methods, the achievements and the aims of science and technology well beyond what has been thought necessary in the past

The problem of the arts student is probably more difficult than that of the scientist and technologist, for while the latter can draw on a vast accumulation of literature in the arts, there is as yet little literature in science and technology that is well suited to his purpose Yet, notwithstanding this difficulty, the time has surely passed when the humanist—or so-called humanist—can continue to remain as ignorant as many now are of the scientific and technological origins of the developments which are changing the pattern of life, both nationally and internationally

The second point is a related one—it is a plea for a more serious attempt to establish what are variously called the human, social or behavioural sciences (if it is yet permissible to refer to them as sciences) in a more rational relationship to the physical and biological ones The scale of effort in the physical sciences and in technology is increasing rapidly The innovations which will result will bring further material benefit, and indeed this is greatly needed in many places and by many people But, as in the past, we are likely to be found woefully incapable of resolving the human problems which will also flow from them I would not know how to set about achieving a better understanding of the factors which govern even the rational modes of human response and behaviour The most I can do is to hope that more good people will devote themselves to the search for it—not in expectation of early benefits, but because longer-term ones will not come otherwise

I have tried to portray the need for, and some of the difficulties that beset, the formulation and implementation of a scientific, technological and technical manpower policy This is, of course, only one aspect of manpower policy within the context of national policy as a whole, and here we are far from having reached a clear concept of the kind of country, and society, we would wish to see emerge with the aid of science and technology

My main theme has been the strengthening of technology. This is only one of the means to the achievement of the wider aims that should inspire us But it is an indispensable means, since I am convinced that only through the material benefits that flow from successful technology shall we be able to afford to do the things which most need doing

NEWS and VIEWS

Chemistry at the University of East Anglia: Prof. N. Sheppard

Dr N Sheppard has been appointed professor of chemistry in the School of Chemical Sciences in the University of East Anglia, Norwich Dr Sheppard went to Hymers College, Hull, and was an undergraduate at St Catharine's College, Cambridge, from which he graduated in 1943 During the Second World War he worked with Dr (now Sir) Gordon Sutherland in the Department of Colloid Science, Cambridge, on the infra-red spectra of rubbers. He obtained a Ph D degree in 1947 and then spent a year as visiting assistant professor at the Pennsylvania State University studying Raman spectroscopy with Prof D H Rank On returning to the United Kingdom, he rejoined the spectroscopy group in the Department of Colloid Science, Cambridge, as a Ramsay Memorial Fellow and later as an 1851 Senior Exhibitioner In 1956 he was appointed assistant director of research in spectroscopy in the University Chemical Laboratory, Cambridge, and a Fellow of Trinity College His research interests have been concerned with the application of spectroscopic methods to the investigation of molecular structure and molecular dynamics His group has applied infra-red spectroscopy to the examination of problems in molecular conformation and internal rotation, hydrogen bonding, and physically and chemically adsorbed molecules In nuclear magnetic resonance spectroscopy the group has principally studied the steric dependence of the (H,H) coupling constant in proton spectra of hydrocarbon groupings—particularly those of simple and symmetrical molecules obtained with the help of spectra from ^{13}CH groups Structural investigations of organic natural-product and inorganic co-ordination compounds have been made in collaboration with colleagues at Cambridge and elsewhere Dr Sheppard has taught physical chemistry at all levels and given undergraduate and postgraduate lecture courses on spectroscopy

Mechanical Engineering at the Manchester College of Science and Technology: Prof J K Royle

Dr J K Royle has been appointed to a second chair in mechanical engineering in the Faculty of Applied Science of the University of Sheffield as from April 1, 1964. Dr Royle, after graduating at the College of Technology, University of Manchester, in 1944, became a scientific officer at the Royal Aircraft Establishment, where, among other things, he worked on power plant, aerodynamics and supersonic flow. In 1949, Dr Royle was appointed assistant lecturer in mechanical engineering in the College of Technology, Manchester, lecturer in 1953, and senior lecturer in 1961 He was an associate professor of mechanical engineering at the Massachusetts Institute of Technology for the session 1960–61. Dr Royle's interests have been in the teaching of fluid mechanics and in research into hydraulic servo-mechanisms. He is the author of a considerable number of papers, for one of which he was awarded the Bernard Hall Prize of the Institution of Mechanical Engineers in 1959 He has acted as consultant to many firms and organizations and he holds a number of patents relating to machine tools, to which many of his developments in hydraulic servos have been applied

The National Research Council (Canada) Steacie Memorial Fellowship: Prof. N. Bartlett

The National Research Council of Canada has announced in Ottawa that Prof Neil Bartlett, associate professor of chemistry in the University of British Columbia, has been awarded the first E W R Steacie Memorial Fellowship by the National Research Council (Canada) This senior research award, established by the Council in March 1963, perpetuates the name of Dr E W R Steacie, president of the Council during 1952–62, and one of Canada's most distinguished scientists (*Nature*, 196, 110, 1962) The purpose of the fellowship is to give outstanding and promising young staff members of Canadian universities the opportunity to spend two or three years in uninterrupted research During his tenure of the award, Prof Bartlett will be relieved of all teaching and administrative duties He will receive his normal university salary, paid in equal shares by the University of British Columbia and by the National Research Council Prof Bartlett, who is thirty-one, became well known when, in October 1962, he prepared the first true compound of the rare gas xenon By successfully combining xenon with another gas to form a stable chemical compound, a reaction previously regarded as impossible, Prof Bartlett not only overthrew a number of existing theories on chemical bonding, but also opened up a whole new field of scientific investigation As a result of his work with xenon, the chemistry of the rare gases is now being examined in laboratories all over the world Prof Bartlett is a native of Newcastle upon Tyne, and holds the degrees of B Sc and Ph D of the University of Durham.

The European–American Nuclear Data Committee

Dr E Bretscher, head of the Nuclear Physics Division of the Atomic Energy Research Establishment, Harwell, was elected chairman for two years of the European–American Nuclear Data Committee at the Committee's sixth meeting held in Athens Dr Bretscher will succeed Dr J Spaepen, head of Euratom's Central Bureau for Nuclear Measurements at Geel in Belgium The secretaries of the Committee are Mr R Batchelor, Atomic Weapons Research Establishment, Aldermaston, and Prof H Goldstein, Columbia University, New York The European–American Nuclear Data Committee was set up in October 1959 by the Steering Committee of the European Nuclear Energy Agency in agreement with Euratom, the United States and Canada The Committee consists of fifteen experts from nuclear establishments in member countries of the Organization for Economic Co-operation and Development The work of the Committee includes periodical reviews of activities in the field of neutron cross-sections, and collation, comparison and diffusion of the results of this work It also establishes lists of priority requests for nuclear data measurements, so as to help in directing and co-ordinating research activities in the participating laboratories and to ensure co-ordination in the use of scarce materials needed for such measurements The Committee was responsible for the recommendations which led to the formation of the European–American Committee on Reactor Physics and the European Nuclear Energy Agency's Group of Specialists on Neutron Data Compilation The Committee has also sponsored various symposia

Building up Education in Britain

In a written answer in the House of Commons on December 5, the Minister of Education, Sir Edward Boyle, stated that the two most important recommendations of the Newsom Report on secondary education addressed to him were those relating to raising the school age and to the school building programme He had recently announced a greatly increased level of school building for 1965–66 and 1966–67, and recognized the importance of continuing the improvement of educational provision in secondary schools on which Britain was already engaged He had already promised to make a statement during the Session about raising the school-leaving age Some work was already in hand relating to other recommendations of the Report He was supporting from his research vote an investigation by the Liverpool Institute of Education of the relationship between environment and educational progress and by the London Institute of Education of the relationship between verbal intelligence, learning ability and social class Consideration of how best to follow up other recommendations was continued, and he would be ready to consider supporting from his research vote other proposals for research and development formulated in this way In reply to an earlier question, Sir Edward Boyle had stated that the increasing recognition throughout the building industry of the need for scientific management techniques, and the inclusion of building management in the examinations of the Institute of Builders, had increased the demand for specialist teachers of building management His Department would shortly be discussing this and other problems with the Institute, and the discussions would cover the question of text-books

British Space Research

In a written answer in the House of Commons on December 5, the Minister of Aviation, Mr J Amery, stated that his Department had been carrying out a programme of research into the technology required for the civil and military exploitation of space, and this programme was at present being reviewed The design study of a communications satellite had been completed and its implications were being investigated Twenty separate systems, including fifteen types of satellite, were considered in a co-operative investigation with the Post Office and industry, and discussions with Europe for British participation in a satellite communications system would be followed by talks with the United States and other countries Britain, he said, was keeping in close touch with the Commonwealth and continued to participate in the negotiations for establishing the European Space Research Organization, the Preparatory Commission of which had placed contracts for two preliminary satellite design studies with the Ministry of Aviation The first *Blue Streak* would be launched from Woomera, probably in April 1964, and under the Minister for Science's space research programme, the second Anglo-American scientific satellite awaited launching in the United States His Department had placed a contract for a third satellite in the programme which would be the first British-made satellite and should be ready for launching by the United States in about three years. Development of a stabilized version of the *Skylark* sounding rocket had reached an advanced stage

Telstar and its Problems

A RECENTLY-PUBLISHED booklet, edited by R. M Foster, jun , *Satellite Communications Physics*, is designed primarily as an aid to school science education (Pp 88 By Members of the Staff of Bell Telephone Laboratories New York Bell Telephone Laboratories, 1963) Written by scientists who have participated in the *Telstar* project, the booklet gives a general review of communications by satellite, followed by six interesting individual 'case histories' on specific questions raised by *Telstar* The six topics are the method of calculating orbits; the choice of colour and surface finish to maintain the required temperatures, the use of optical observations to determine the direction of the spin axis, the protection of solar cells from radiation damage; the effects of time delays of up to 1 2 sec in telephone conversations via a synchronous satellite, and, finally, the problem of repairing a satellite in orbit

Research and Design in Engineering

In a lecture entitled "Research and Design in Engineering", originally delivered at the National Engineering Laboratory in October 1962, and which has only been published this autumn, Mr H Clausen renews the plea for a better balance between the science and the art of engineering which he had advanced in earlier lectures on engineering design as the background and basis of contemporary life and on the borderland between science and engineering. Quoting a remark of Sir Henry Tizard that science may make many things possible but does not necessarily make them happen, Mr Clausen suggests that Britain's educational and industrial weaknesses still call for more attention at the point where two disciplines, fields of activity, or techniques overlap The problem is largely one of communication of ideas and media of expression He suggests that the gap between research and the application of its results is due first to the disappearance of the older relation between master and apprentice and then to the failure, in the educational, engineering and industrial fields, to develop some system to replace it effectively Probably arising out of the latter is the failure of Britain's older educational system to realize that national leadership cannot be effective without a full appreciation of the way the country earns, or might be able to earn, its living a mastery of the industrial arts, on which everything depends, and which can no longer be taken for granted Probably, in consequence, the control of much industry has drifted into the hands of men who are mainly interested in finance and profits and have pushed the creative aspects of industry, on which everything depends, so far down in the hierarchy that they are no longer effective, or attractive to men of talent, quality or ambition Finally, he insists that Britain's existence as an independent nation depends on maintaining a proper balance between science and the technologies

Industrial Psychology and Take-over Bids

A STUDY by Mrs W Raphael and Mr M W Zimmerman of the reactions of some 5,500 employees in a group of electrical equipment companies indicates that unrest and anxiety among employees whose firm has been taken over by another could be reduced if they were given more information as soon as possible after the change occurs (National Institute of Industrial Psychology. Report No 15 *After the Take Over—A Study of Reactions of Employees in a Group of Companies* Pp iii+35 London National Institute of Industrial Psychology, 1963) Two surveys were made one shortly after the take-over, and a similar survey about a year later At the time of the first survey, people were anxious about their jobs and initially excited rather than despondent about the future, and willing to co-operate rather than tending to resist all change. The Institute comments that even if few changes are intended, it is better to explain the nature of those that are intended than to say there will be few Employees will be reassured more by knowledge of the direction that affairs will take than by general expressions of benevolence The results of the second survey are treated with more reserve. and a particular distinction is suggested between the purposes of take-overs On the whole, views about the effects on companies and on products and customers remained favourable Ignorance of the procedure by which a take-over is conducted was widespread a circular which explained this procedure and its reasons could help to allay the suspicions to which misunderstandings lead

British Aid to Developing Countries

A FURTHER pamphlet in the series of independent factual surveys of British aid being issued by the Overseas Development Institute, Ltd , reviews the main features of aid to developing countries, completing the picture given in the White Paper issued in September (*British Aid—1· Survey and Comment.* Pp 63 London Overseas Development Institute, Ltd , 1963 3*s* 6*d*) Objectives, organization, financial assistance, technical assistance and, finally, education and training, are discussed in successive chapters, and in the last three chapters the factual survey is followed by critical comments As regards objectives, attention is directed to the need for more public explanation and discussion of the more specific aims of aid if policy is to be deliberate, consistent and publicly supported On organization, establishment of a Ministry for Overseas Development with a senior Minister at its head is suggested This Ministry would take over from the external affairs departments the responsibility for policy-making and allocation of aid An Agency or service department, it considers, should be established to handle the technical aspects of aid, but policy would remain in the hands of the present departments—the Agency acting as adviser—while a senior Minister should be appointed to act as general overseer of aid and its spokesman The pamphlet is critical of some aspects of technical assistance, particularly emphasizing the need for an overseas career service and suggesting also a home-based technical advisory service Accordingly, it suggests that recruitment could be improved by making contracts significantly longer, and more attractive, and by more determined efforts at making an overseas tour of duty an accepted part of a successful career On education, it questions whether the 7 per cent of Government aid devoted to educational assistance represents the right order of magnitude It strongly urges the need for more educational research, particularly in determining the priorities of need in the developing countries and the relative efficiency, and actual costing, of various methods of educational assistance Apart from its value as a concise factual summary, the pamphlet is to be commended for its constructive criticism which, except perhaps in the matter of organization, is sound as well as informed

Conservation of Nature and Landscape

AT the second meeting of the Committee of Experts for the conservation of Nature and landscape, held in Strasbourg during November 12–15, Mr J. P Harroy (Belgium) was elected chairman, and Mr W B Yapp (Britain) and Mr Z Bayer (Turkey) were elected vice-chairmen. The agenda included soil conservation and unwise use of land; preparation of a map of potential natural vegetation in European countries, water conservation; pesticides, sea pollution, criteria to be adopted for the selection of biotopes to be preserved in Europe and list of these biotopes, plant and animal species threatened by extinction, a European label for protected objects; protected areas in Europe, education and information; national legislation on Nature conservation The Committee of Experts asked the Committee of Ministers to recommend that member States (1) take care in pursuing their forestry policies and conifer-planting projects to respect the principles of soil and water conservation and to protect fish and game, (2) ensure the protection of unusual biotopes and the preservation of the character and harmony of the landscape whenever these are threatened by such projects, (3) take preventive measures to conserve aquatic life by reserving a strip of land on either side of water-courses where the natural vegetation must be conserved, (4) hasten the ratification of amendments to the 1954 International Convention for the prevention of Pollution of the Sea by Oil, and the provision of facilities for the reception of oil residues in ports The Committee of Ministers was also asked to repeat its recommendation to Governments to hasten the ratification and full application of the 1950 International Convention for the protection of birds The next session of the Committee is scheduled for July 21, 1964

Systematics

THE Institute for the Comparative Study of History, Philosophy and the Sciences was founded in 1946 to conduct research and other scientific work relating to the problem of human perfectability, or the factors that determine progress or retrogression in individuals and communities Coombe Springs, the headquarters of the Institute, has been a laboratory for studying ideas and methods directed to progress Some of the results of this experimental work have been published, and the desire to bring this work before a wider audience has led to the decision to launch a journal, *Systematics*, which is intended to become the principal medium for the publications of research work conducted by the Institute itself (1, No 1; June 1963 The Journal of the Institute for the Comparative Study of History, Philosophy and the Sciences Pp 1–103 Kingston upon Thames Coombe Springs Press, 1963 Annual subscription 42*s* non-members, 30*s* members Separate issues 11*s* 6d non-members; 8*s* 6*d* members) The title has been chosen as expressing the fundamental notion of integration without rejection, which has been the guiding principle in the work at Coombe Springs For papers to be accepted for publication in the journal they must bear on the systematic hypothesis and show sufficient originality in content or treatment to contribute significantly to the better understanding of human development they may deal with any branch of history, philosophy and science, including psychology Two numbers of the new journal have now been published That for June 1963 includes, besides J G Bennett's paper on general systematics, A. M. Hodgson's short paper on the education of technologists, describing a project of the Integral Science Education Research Group. The September 1963 issue includes a paper, "Systematics of a Manufacturing Process", based on a study by the late C E King, chief engineer of Vauxhall Motors, Ltd , and one by J G Bennett, "Geophysics and Human History", discussing some new light on Plato's Atlantis and the Exodus

Piston Gauge Pressure Measurements

THE dead-weight piston gauge, also called the 'gauge-tester', 'dead-weight tester', 'pressure balance' and 'piston manometer', can be used to measure pressure in terms of the fundamental units of force and area. The piston is inserted into a close-fitting cylinder, and weights loaded on one end of the piston are supported by fluid pressure applied to the other end. The construction varies as to the method of loading, the methods of rotating or oscillating the piston to reduce friction, and the design of the piston and cylinder. Errors in the measurement of pressure with the gauge arise from failure to take into account the parameters of the instrument or environment, or from uncertainty as to their measured values. In National Bureau of Standards Monograph 65, J. L. Cross discusses the variables which affect the pressure measurement and presents a general equation and simplified procedures for the calculation of the pressure (*Reduction of Data for Piston Gage Pressure Measurements*. By J. L. Cross. Pp. iii+9. Washington, D.C.: Government Printing Office, 1963. 15 cents.) Uncertainty of the mass of the loading weights and of measurements of the effective area of the piston and cylinder is an obvious cause of error. Less easily recognized sources of error are air buoyancy on the weights, fluid buoyancy on the piston, the value of local gravity, the force on the piston because of the surface tension of the fluid, thermal expansion and elastic deformation of the piston and cylinder, and the fluid heads involved. In the various appendixes to the monograph, working equations, examples of calculations and guides for compiling correction tables are given.

Farm Motorization, Consumption and Prices of Motor Fuels

Development of Farm Motorization and Consumption and Prices of Motor Fuels in Member Countries is the title of a publication recently issued by the Organization for Economic Co-operation and Development (Pp. 96. Paris: Organization for Economic Co-operation and Development, 1963.) It is essentially statistical in outlook although relieved by pertinent comments on developments of interest to all concerned with European trends in replacement of manpower by machines in agriculture. The report is divided into three sections: (*A*) development of motorization from pre-war until 1960; (*B*) consumption of motor fuels used in agriculture from 1952 until 1960; (*C*) development of prices of motor fuels from 1950 until 1960. In the summary under (*A*), the main conclusions reached are that the number of farm tractors has steadily increased commensurate with the equally steady decline in available active agricultural (human) and draught animal populations. In section (*B*), dealing with consumption of motor fuels in European agriculture during 1952–60, "... it can be stated that the increase by 61 per cent was less noticeable than the rise in the number of tractors by 161 per cent for the same period. Consequently, the annual average consumption per tractor declined for the European O.E.C.D. area as a whole from 2,100 kg in 1952 to 1,600 kg in 1960 and that per horse-power from 82 kg to 66 kg accordingly". It is thought that the future trend will be slowed down because farmers will make a wider and more efficient use of their modern tractors annually compared with past years. As regards prices for motor fuels used in agriculture in countries covered by this report, the conclusion is reached that farmers' expenses for this vital factor in their economy are increasing annually, reaching in 1960 the somewhat staggering total of about 491 million U.S. dollars, naïvely described as "... rather an important cost factor of agricultural production".

Mineral Dust in Industry

THE proceedings of a symposium, *Mineral Dust in Industry*, which was held in the laboratories of the British Ceramic Research Association, Stoke-on-Trent, during December 19–21, 1961, have recently been published (Pp. v+153. London: H.M.S.O., 1963. 22*s*. 6*d*. net.) The symposium was sponsored by the Department of Scientific and Industrial Research which is showing increasing interest in industrial health, which is not unreasonable because of the close relationship between health, the human working environment and the engineering, physics and chemistry of the processes and products which are being handled. In the symposium are papers on pneumoconiosis (dust disease of the lung) in the pottery and foundry industries. The latest magic word 'parameter' comes up in a description of the biological significance of dust parameters but, happily, there is no excess usage of the word 'integrate'. The sampling and control of dust and technicalities of instrumentation are dealt with, as also are ventilation of dusty shops, the design of protective clothing for the workpeople, and the amount of disability which they may suffer if they breathe in dust for long enough. The title of the booklet is a little wide for its subject range, in view of the large areas of the problem unmentioned. The contents possess a medical bias rather than one of fundamental physics and chemistry, and the emphasis is a little on potteries. It is interesting to note that in the study of dusts the physics is well ahead of the chemistry, and little appears to be known, as yet, about what happens on the surface of a particle of dust when it is inside a biological cell. The booklet is well charted and illustrated and will be useful for anyone with either a medical or technical interest in mineral dust.

Nutrient Requirements of Livestock: Poultry

THE first of the Agricultural Research Council's pamphlets on *The Nutrient Requirements of Farm Livestock* has recently been published (No. 1. *Poultry—Summary of Recommendations*. Pp. v+50. London: Agricultural Research Council. Obtainable from H.M.S.O., 1963. 2*s*. 6*d*.) It covers the needs of "all those tame birds reared for their flesh, eggs or feathers, and provides some information about the pheasant". The intention is that the *Summary* shall be brought up to date periodically, and that Technical Reviews will detail the mass of material now abridged. Although special attention has been paid to conditions in the United Kingdom, and therefore to British experiments, the recommendations differ little from those of the U.S. National Research Council since, indeed, American studies predominate overwhelmingly in this field. Feed compounders and farmers will not, therefore, gain an immediate advantage from this statement. However, since each section provides a precise and careful examination of present-day knowledge, it exposes the deficiencies of available information and should stimulate work in these areas. Subsequent issues should profit from this; so, too, should research workers, teachers and students, who will also be grateful for the comprehensive sectional bibliographies. To-day, the poultry industry is changing rapidly both with respect to the breeding of the birds it exploits and in its husbandry techniques. It can be anticipated that its most costly item, feeding stuffs, will be improved concurrently, and that this pamphlet will be a standard reference point in this development.

Folklore in French Canada

Bulletin No. 182 of the National Museum of Canada describes the work of recording folk traditions in the Islands of Saint-Pierre and Miquelon (*Saint-Pierre et Miquelon: Une Mission Folklorique aux îles*. Pp. 192. Par Carmen Roy. Ottawa: Imprimeur de la Reine et Contrôleur de la Papeterie, 1963. 3 dollars.) A description of the area, its history and economy, and its people, introduces the major portion of the Bulletin, which considers the traditions under various headings, including place-names, customs and beliefs, stories and songs. Full transcriptions are given where possible The overall work is an outstanding contribution to folklore studies, and it is hoped to extend this to other areas which also form a part of the Acadian group of French Canada

Bulletin No 188 of the National Museum of Canada describes the moulds of early historic times in Quebec (*Les Moules du Québec* Pp vii+141 (75 plates) Par Robert-Lionel Seguin Ottawa Imprimeur de la Reine, 1963 2 50 dollars) This is the first in a series of *Bulletins d'Histoire* The moulds are classified on the basis of function of their products, and represent the household equipment of a time when manufactured products were otherwise not available The most common are moulds for the shaping of food, maple sugar, butter and pastry Some of these wooden moulds are skilfully carved to produce animal and other figures Moulds for religious purposes, for the making of altar breads, are also included The itinerant tinkers' moulds include sets for religious figures and domestic objects such as spoons, goblets and buttons The report is well illustrated and documented Typical household sets might well have been grouped or listed together Further *Bulletins* in this series should continue to provide more insight into the way of life of seventeenth to nineteenth century Quebec

Archæology in South Africa

THE *South African Archæological Bulletin* for June (17, No 66, 1963), which has recently been published, contains a number of interesting articles Dr J T Robinson describes at some length the Sterkfontein stratigraphy and the significance of the extension site, and later, in part 2, R J Mason describes the tools found, both parts are well illustrated So much has been said about this site, where almost the earliest works of man have been found, that it is admirable that in this number of the *Bulletin* a more or less complete account of the artefacts of these Australopithecines, as well as of where they lived, is now easily available In a supplement to the *Bulletin*, R J Mason pays tribute to the work of the late C Van Riet Lowe and lists his principal publications during the period 1922–57 There is also a report on the Research Unit of the University of the Witwatersrand, to which the Archæological Survey has been transferred

The American Society for the Study of Sterility

THE following three awards will be presented at the annual meeting of the American Society for the Study of Sterility to be held at Bal Harbour, Florida, during May 15–17, 1964 *The Ortho Medal* and a sum of 1,000 dollars will be awarded to a recipient selected by the Awards Committee of the Society on the basis of his outstanding contributions in fertility and sterility or related subjects in recent years. The money is to be used by the recipient for expenses in visiting medical and research centres of his choice *The Rubin Award*, consisting of a certificate of merit and the sum of 250 dollars, will be awarded to the author(s) whose paper is deemed by the Awards Committee to be the most significant contribution among those appearing in the Society's journal, *Fertility and Sterility*, during the year 1963 *The Carl G Hartman Grant-in-aid* of 500 dollars will be awarded to the most meritorious research project in fertility and sterility or related subjects, as chosen by the Awards Committee Applications for the grant-in-aid should be sent to Dr Michael Newton, American Society for the Study of Sterility, 2500 North State Street, Jackson 6, Mississippi, before March 15, 1964, from whom further information can also be obtained

The Night Sky in January

NEW moon occurs on Jan 14d 20h 44m U T and full moon on Jan 28d 23h 23m The following conjunctions with the Moon occur Jan 17d 01h Saturn 2° N , Jan 17d 17h, Venus 3° N , Jan 20d 19h, Jupiter 4° N Venus is in conjunction with Saturn on Jan 9d 22h, Venus being 0 6° S There is a partial eclipse of the Sun on January 14, invisible at Greenwich Mercury is a morning star, but is not well placed for observation Venus is an evening star, setting at 18h 30m, 19h 15m and 20h 5m on Jan 1, 15 and 31, respectively Its stellar magnitude is −3 4, its distance decreases during the month from 128 to 111 million miles, and the visible portion of the apparent disk from 0 862 to 0 786 Mars is too close to the Sun for observation Jupiter sets at 0h 20m, 23h 30m and 22h 40m at the beginning, middle and end of the month, respectively Its stellar magnitude is −1 9 and its distance from the Earth on January 15 is 470 million miles Saturn sets about two hours after the Sun, and conditions for observation are now unfavourable The Quadrantid meteors are active on January 3–4, the radiant being near R A 15h 28m, Dec +50° The Earth is at perihelion on January 2, its distance from the Sun being 91 3 million miles

Announcements

A SYMPOSIUM on "Major Weather Hazard Affecting British Agriculture" will be held in the Department of Geography and Anthropology, University of Wales, on March 18 Further information can be obtained from Mr J A Taylor, Department of Geography and Anthropology, Alexandra Road, Aberystwyth, Cardiganshire Wales

THE eighteenth annual symposium on fundamental cancer research entitled "Cellular Radiation Biology", organized under the auspices of the M D Anderson Hospital and Tumor Institute, University of Texas, will be held in Houston during March 2–4 Further information can be obtained from the M D Anderson Hospital and Tumor Institute, University of Texas, Houston, Texas

THE third European regional conference on "Electron Microscopy", organized by the National Committee for Electron Microscopy of the Czechoslovak Academy of Science under the auspices of the International Federation of Societies for Electron Microscopy, will be held in Prague during August 26–September 3 Further information can be obtained from the Organizing Committee, Albertov 4, Prague 2

A TWO-DAY course on "Expanded Plastics" will be held at the Bradford Institute of Technology during February 6–7 The programme will include chemical aspects of expanded polymers; the physical and mechanical properties of expanded polymers, developments in urethane foams, developments in expanded polystyrene, expanded polyvinyl chloride, expanded ebonite Further information can be obtained from R P Sheldon, Department of Chemical Technology, Bradford Institute of Technology, Bradford 7

A CONFERENCE on "Low and Medium Energy Nuclear Physics", arranged by the Institute of Physics and the Physical Society, will be held in the University of Sussex during September 9–11 Topics under consideration will include nuclear structure, electromagnetic and weak interactions, two nucleon potential and Brueckner theory, nuclear reactions Further information can be obtained from the Administration Assistant, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S W 1

A JOINT computer conference on "The Impact of the Users' Needs on the Design of Data Processing Systems", arranged by the British Computer Society, the British Institution of Radio Engineers and the Institution of Electrical Engineers under the ægis of the British Conference on Automation and Computation, will be held in Edinburgh during March 31–April 3 Further information can be obtained from the Computer Conference Secretariat, Institution of Electrical Engineers, Savoy Place, London, W C 2

POINT DEFECTS IN NON-METALLIC SOLIDS

DIAMONDS, graphite, oxides and phosphides, zeolites and alumino-silicates all came up for discussion at a conference at Leamington Spa organized by the British Ceramic Society through its Basic Science Committee during October 14–16, 1963. The wisdom of making the programme so wide as regards materials examined, and so well defined in limiting the discussions to the properties of point defects, was exemplified by the liveliness of the discussions and the encouraging overlap of the technical terms now current in the field. Despite the wide selection of materials the majority of the audience was interested for the majority of the time. From the point of view of a physicist, one of the most encouraging features was the growth of the recognition that the basic properties of any pure material need to be isolated from those deriving from the defects it contains. This recognition has spurred on the production of purer materials for investigation. Of course, the example of semi-conductors and the immediate pressure of laser and maser requirements has given a real edge to these considerations, and the preparation of large, highly pure crystals of many halides and a few oxides is now possible.

There are two kinds of purity to be discussed for these ionic substances; chemical contamination by extraneous material must be avoided, but also, perhaps less obviously, the proper proportions of the main constituents to produce a stoichiometric crystal must be maintained. It was with two papers on this topic that the conference opened. It was shown that careful density and lattice parameter work can give information on the numbers of vacant lattice sites, and that extra diffraction lines may betray complex ordering behaviour of the defects. The advantages of neutron diffraction over X-rays were brought out clearly by investigations of oxygen defects in compounds between UO_2 and U_4O_9. Another paper in this section showed how the electron microscope can identify small clusters of defects as interstitial atom groups rather than vacancy aggregates.

The difficulties of positive identification of individual defect centres in II–VI compounds were outlined, but the conference quickly settled down on the second day to detailed discussion of recent experimental information on alkali halides, diamond, magnesia and rutile. Most of these papers sought to set up models to account for the electron spin resonance or optical properties. In diamond, magnesia and calcium fluoride, many of the optical bands have now been shown to have sharp, zero-phonon, lines at the high-energy edge of the band. It is often of good intensity and, in one case at least, was split by application of stress to the diamond. There seems no doubt that such lines will repay more detailed investigation than has been possible on the broad bands seen hitherto.

Coloration in rutile under irradiation has been investigated at Brookhaven Laboratories, but virtually no specific effects in the optical spectrum can be identified. A general small rise in absorption is all that has been seen in room temperature irradiation experiments on crystals of carefully controlled stoichiometry. Photoconduction peaks were, however, produced by neutron irradiation.

Impurity coloration due to cupric ion in a number of solvent crystals—ZnO, MgO and ThO_2—was interpreted as demonstrating marked differences in the ion's electric levels in crystal fields of different symmetries. The effects of tetragonal Jahn-Teller distortions from cubic symmetry were identified and values of the crystal field splitting parameter tabulated. The explanation of the susceptibility of the cupric oxide crystal itself seems to demand some significant antiferromagnetic coupling of pairs of spins even in the paramagnetic state.

The next section of the meeting was concerned with atomic mobility in solids. It was interesting to have some discussion at last of the role of anion vacancies and interstitials in simple ionic crystals, and some experimental evidence that they could not be permanently ignored was presented. The analysis of diffusion mechanism has always been fruitful in identifying the most mobile of the possible atomic defects, and it is most impressive now to hear of the delicacy and accuracy of the experiments which allow the relative rates of motion of different isotopes to be followed. The measurements on ^{22}Na and ^{24}Na in sodium chloride have shown again that the most exacting test is still satisfied by the idea that anion vacancy diffusion is dominant. That the fluctuation in the kinetic energy to carry the system to the 'activated complex' state resides mainly on the jumping atom is established by the closeness with which the basic rates are proportional to the square root of the mass of the jumping atom. The discussion brought to light some interesting measurements from the Imperial College of Science and Technology on the charges absorbed on dislocations, which were interpreted as a measurement of the different partial supersaturation of positive and negative ion vacancies in sodium chloride, and hence of their energies of formation. Despite some reservations as to the rigour of the argument, this seemed a promising new departure. Another short contribution from the same group showed how the temperature range, where diffusion rates are intrinsic, can be extended in the alkali halides by adding oxide or sulphate ions to depress the number of non-thermal free positive-ion vacancies. The observed absence of a reduction in diffusion coefficient below the intrinsic line is hard to understand. This section closed with an address dealing with the significance of the non-equilibrium thermodynamic formulation of atomic mobility, which showed that, despite (or because of ?) its generality, it was easy to fall into error by failing to define carefully all the variables and their interdependences. For example, vacancy flux must be introduced with care since it can be deduced from atomic fluxes for some boundary conditions and not for others. It was concluded that it was worth while to develop some familiarity with the formation by translating the results of some atomic models into the language of irreversible thermodynamics, before trying to use the technique in unfamiliar situations.

Prof. Barrer gave a succinct guide to the features controlling ionic diffusion in various zeolite-type structures. In some of these, wide continuous channels exist and diffusion barriers are essentially electrostatic in nature, but in others, narrow points separate atomic cages, and repulsive forces come into play. The connexions between surface chemistry, surface diffusion, and bulk diffusion became obvious, and the practical importance of interdisciplinary conferences of this kind was again emphasized in the minds of those present.

The intricate question of how ionic is a salt was raised by a paper on the E.M.F. of the diffusion cell. It was shown that the transport of charge during diffusion of, say, aluminium atoms through alumina is not necessarily precisely that corresponding to the motion of Al^{+++} ions. The actual value depends on the precise mechanisms of compensation of the charges of the defects responsible for diffusion.

The final section related to the mechanical properties of ionic solids, as affected by point defect. The introductory lecture by Prof. Pratt showed clearly that two main categories of effects could be considered, the direct effects of defects or their aggregates, and the indirect effect of the interaction of the defects with pre-existing dislocation or dislocations formed by mechanical deformation. It appears that in some circumstances a main effect may be the indirect pinning of dislocations by their electrostatic or stress interaction with re-orientable dipole-type defects. A short paper on sodium chloride with controlled concentration of divalent cations supported this view. The nature of the relaxation of dipoles formed by trapped defects was discussed in group theoretical terms in the next paper, and it was shown that except for very short times a single relaxation time appropriate to nearest neighbour orientations of the defect is reasonably accurate.

The effects of irradiation on the plastic properties of sodium chloride showed a rise in yield stress, a tendency to smaller slip-step heights and to simultaneous slip on equivalent planes with suppression of kinking. None of the changes was related to *F*-band colour, but *V* band and interstitial density were not checked. The effects observed in the Youngs modulus of polycrystalline graphite after low-temperature electron irradiation appeared to be due to the pinning of dislocations, but no detailed mechanism could be proposed.

Electron microscope examinations have been made on a number of deformed and defective crystals. The development of oxygen deficiency in titanium dioxide helps the annealing out of stacking faults by a mechanism which may well involve the dissolution of titanium interstitial atoms, after condensation of oxygen vacancies has eliminated planes of oxygen. The titanium interstitials are in fact identified by colour studies. Other dislocation reactions have also been observed. A separate group reported an increase in optical absorption associated with an increase in titanium interstitial content after high-temperature plastic deformation of an already oxygen-deficient titanium dioxide crystal, and also attributed this to either stacking fault elimination or to dislocation climb. In view of the lack of structure in the optical absorption investigations, several comments were made to the effect that an increase in titanium interstitial content could not yet be accepted as proved. Electron microscope examinations were also reported on plastically deformed TiO, and annealing investigations pointed to an activation energy of some 5.5 eV for atomic mobility.

To sum up, this was a good conference to be at. It brought together groups of people who meet too seldom, and showed again the unity of the physical sciences. It was the right size—about 120 people—and the programme was not so packed that it was impossible to find a moment to talk to most of those one meant to. The wisdom of holding the conference during university term, when many people found it hard to be away for three days, and when it was not possible to use the lecture theatres of a university, may be queried. A proper lecture room is really quite important, though not nearly so important as the programme, content and participants. I am sure the success of this meeting will encourage the British Ceramic Society to hold more meetings of similar kind to bring these neglected substances under regular scientific review.

W. M. Lomer

MECHANISMS OF ADSORPTION FROM SOLUTION

An informal discussion of the Faraday Society under the above title was held in the Department of Mechanical Engineering, Imperial College of Science and Technology, during September 19–20, by kind permission of Prof. O. A. Saunders. The meeting was attended by 144 people, 81 of whom came from industrial organizations and 63 from academic institutions. There were 16 overseas visitors.

Sir Eric Rideal opened the meeting and, as the first item, Dr. J. J. Kipling (University of Hull) gave a review of the present position in this subject. After outlining the main historical periods, and the progress which was made in each, Dr. Kipling discussed at some length the problems encountered when, instead of an adsorbing vapour, we have to deal with a two (or more) component liquid system. The basic equation relating changes in the surface and bulk mole fractions of the components was given, and its relation to the Gibbs surface excess and the individual adsorption isotherms for the components was described. The use of adsorption from solution for measurement of surface area was examined critically, and, in particular, the difficulty of selecting an appropriate cross-sectional area for the adsorbate molecule was stressed. The difficulty of satisfactorily taking into account localized site adsorption was also discussed. Finally, Dr. Kipling mentioned the question of chemisorption of molecules from solution and foresaw the problem well known in vapour adsorption of distinguishing between chemically and physically adsorbed molecules.

The first paper was given by Prof. D. H. Everett (University of Bristol) and was entitled "Thermodynamic Models of Adsorption from Solution". The adsorption of the components of a binary liquid mixture on to a uniform surface was described in statistical mechanical terms and a new definition of the activity coefficients of the components in the adsorbed layers was proposed. Prof. Everett showed that the "isotherm of concentration change" may be markedly dependent on the nature of the solution concerned, for example, whether it is a regular solution, or contains molecules of different size. The use of adsorption from solution for the determination of specific surface areas was mentioned and it was suggested that useful results could be obtained from measurements of adsorption from mixtures of molecules of approximately the same size (for example, *cyclo*hexane + benzene).

This was followed by a paper on the "Thickness and Structure of Layers of High Polymers adsorbed from Solutions to Solid Surfaces", by F. Rowland, R. Bulas and Prof. F. R. Eirich (Polytechnic Institute, Brooklyn, New York). The paper was given by Prof. Eirich, who explained the difficulties and uncertainties of investigating the nature of polymer adsorption and then presented results obtained principally by observing the change in flow of liquids through sintered glass disks of known pore size distributions and surface areas. From an analysis of the hydrodynamics of the system, the change in effective radius of the capillaries resulting from polymer adsorption was estimated. Several polymers in different non-aqueous solvents have been examined and it was shown that the film thicknesses were of the same order of magnitude as the diameters of the free coils in solution. A detailed discussion was given of the nature of the adsorption isotherms, of their reversibility and of the influence of good and bad solvents.

A contribution to the investigation of the adsorption of ionized polymers was made by J. B. Craig and Dr. P. Meares (University of Aberdeen) under the title "The Adsorption of Polyacrylates at a Charged Mercury–Salt Solution Interface". Experimental data had been obtained from electrocapillarity investigations, and from derived thermodynamic relations, the surface excess concentrations of polyanions, counter-ions and co-ions were estimated. The plot of surface excess of polyanion against increasing bulk concentration showed a maximum followed by a decrease to an almost constant value. A detailed model was proposed to account for this and related phenomena which was based on configurational changes of the polyanions normal and parallel to the surface. From the calculated co-ion surface excesses an estimate was made of the thickness of the adsorbed polyion film; this appeared, in some cases, to be greater than one monolayer.

On the following morning, under the chairmanship of Dr J. A. Kitchener, Dr C. H. Giles (University of Glasgow) presented a paper on "The Association of Adsorbed Organic Solutes". The adsorption of a number of organic molecules, many of them dyes, on to a variety of adsorbents was described and compared with the surface area indicated by *p*-nitrophenol adsorption. The differences relative to *p*-nitrophenol were expressed as 'coverage factors', and it was shown that these factors bore a simple relation to the molecular weight of the adsorbate. The 'coverage factors' were suggested to arise from the adsorption of the organic molecules as an aggregate or micelle. Some direct evidence for such a phenomenon was presented.

"Adsorption of Cyanine Dyes at Silver Halide Surfaces" was the title of a paper by Dr J. F. Padday (Kodak, Ltd.). The surface areas of specimens of silver chloride, bromide and iodide were determined from argon and benzene vapour adsorption. It was deduced that under conditions of close packing of the cyanine dyes at the crystal surfaces the area per molecule of a given dye was different for the various halides. From this evidence and from measurements of spectral reflectance the manner in which the substrate affected the state of the dye was discussed.

The chairman for the final session was Prof. F. C. Tompkins. In the first part Dr I. T. Smith (Paint Research Station, Teddington) gave a paper on "An Infrared Spectroscopic Study of the Adsorption of Carboxylic Acids on Titanium Dioxide Pigments". After adsorption equilibrium had been established in each case, for a variety of carboxylic acids in benzene in contact with several different samples of titanium dioxide, the oxide was made into disks and examined by absorption spectroscopy. The results suggested that the acids were bound to the oxides, either through a carboxylate ion, or by means of hydrogen bonds. Both types of bonding could usually be found for a given pigment. It was found that on washing the oxide with its adsorbed molecules in pure solvent the hydrogen bonded molecules, but not perceptibly the ions, were removed. Immersion in the original acid solution restored the specimen to its original state.

The meeting ended with an extended discussion on the adsorption of polar molecules on to metal oxides. Dr J. J. Kipling and Dr E. H. M. Wright mentioned that stearic acid molecules adsorbed from benzene on to silica lay flat on the surface, but on alumina and titanium dioxide were approximately vertical. They also showed that for stearic acid on titanium dioxide and alumina the adsorption was close to that expected for a localized adsorption on to lattice points. Dr D. A. Haydon and P. T. Dawson (University of Cambridge) described the effectively irreversible adsorption at 20° C of formic acid from the vapour phase and stearic acid from benzene on three different dry activated rutiles. The possible reasons for a slightly lower adsorption, in all cases, of stearic acid relative to formic were discussed. Both stearic and formic acids gave fractional coverages relative to nitrogen of approximately 0.5. Dr G. D. Parfitt and I. J. Wiltshire (University of Nottingham) discussed the adsorption of a homologous series of aliphatic alcohols from xylene on to a pure rutile. The amount of alcohol adsorbed showed a strong dependence on chain-length, being a minimum at octanol. Prof. Everett commented that such behaviour might be expected from his theoretical treatment of adsorption. The important part played by adsorbed water on the rutile surface in the adsorption process was also stressed.

During the meeting it was announced that it was proposed to hold a further meeting during September 17–18, 1964, in the Chemistry Department, University of Bristol, on the subject, "The Electrical Double Layer in Surface and Colloid Chemistry".

D. A. HAYDON
R. H. OTTEWILL

METABOLISM AND PHYSIOLOGICAL SIGNIFICANCE OF LIPIDS

LIPID biochemistry is one of the scientific topics which have become prominent during the past fifteen years, due both to major technical advances easing their study and to fundamental observations showing their importance. Thus only part of the field could be surveyed at the advanced study conference on the metabolism and physiological significance of lipids, held at Cambridge during September 16–21, 1963, and supported by the Scientific Affairs Division of NATO, although about 150 participants (from institutions in sixteen countries, of which six do not belong to NATO) heard 38 formal discourses given at nine day-time sessions, besides two informal evening symposia, and were admirably provided by the organizers, Drs R. M. C. Dawson and D. N. Rhodes (Great Britain), with time and electronic encouragement for free discussion.

The first major topic was lipid biosynthesis. Prof. S. J. Wakil (United States) began by describing how animals form long-chain fatty acids. First, a reductive synthesis of saturated acids from malonyl and acetyl coenzyme *A* gives mainly palmitate; it, or longer-chain acids, can then be oxidatively desaturated. Secondly, in the most recently examined process, acetyl coenzyme *A* provides two carbon atoms for the reductive chain-lengthening of saturated or unsaturated acids; thus palmitoleate gives *cis*-vaccenate, now known to be an important component of 'oleate'.

According to Prof. K. Bloch (United States), some organisms form unsaturated acids anaerobically by the dehydration of hydroxy acids, but most do so aerobically. Only green plants can make linoleate, which is then further dehydrogenated via α-linolenate; or, in animals, via γ-linolenate. The route used and the type of compound lipid produced by green euglenids depend on whether they are functioning as plants or animals. Photosynthetic bacteria do not produce polyunsaturated fatty acids, which may therefore be specifically concerned in plants' oxygen-yielding type of photosynthesis.

Prof. B. Shapiro (Israel) said that synthesis of triglycerides by the labile enzyme systems of liver preparations *in vitro* is greatly assisted by lecithin or by serum proteins, and closely dependent on the concentration of α-glycerophosphate, which varies enormously under different physiological conditions *in vivo* and may therefore control the process.

Dr G. Popják (Great Britain) then showed how deuterium-labelled mevalonate and tritium-labelled pyridine nucleotides of known absolute configuration have been used to establish the precise stereochemical specificity of the reactions whereby mevalonate is converted via its pyrophosphate and isopentenyl, geranyl and farnesyl pyrophosphates into squalene, the precursor of steroids.

Prof G V Marinetti (United States) had examined glycerol metabolism in rat liver homogenates, important products were dihydroxyacetone, phospholipids and glycerides. Adenosine triphosphate stimulated lipid biosynthesis, with high concentrations, the only lipid formed was phosphatidic acid

According to Dr R O Brady (United States), the first specific precursor of animal glycolipids is palmitaldehyde its acquisition from serine of one nitrogen and two carbon atoms and subsequent dehydrogenation yields sphingosine, which then reacts with uridine diphosphate galactose to form psychosine, reaction of an acyl coenzyme *A* with the amino group to form the amide then completes the biosynthesis of a cerebroside Higher glycolipids probably result from the addition of further sugars, etc , to the cerebrosides

Dr J Asselineau (France) then explained how the very large and complex molecules of the higher fatty acids of mycobacteria are formed by comparatively simple mechanisms, comprising methylations, such as that of oleate to give tuberculostearate, the condensation of propionate residues with each other and with higher acids yielding the phthienoic and mycocerosic acids, and finally, the condensation of long-chain α-hydroxy acids to give the branched-chain hydroxylated mycolic acids of nearly 90 carbon atoms

Two plant fatty-acid-forming systems described by Prof P K Stumpf (United States) resembled animal mechanisms examined by Prof Wakil, one synthesized saturated acids from malonyl coenzyme *A*, while the other lengthened the carbon chain of assorted acids, ricinoleate being one product Thirdly, the safflower seed made linoleate from acetyl rather than malonyl coenzyme *A*, a single gene controlled the synthesis of linoleate instead of oleate

Discussion of the further metabolism of lipids began with an examination of the enzymatic hydrolysis of fats Dr P Desnuelle (France) has developed a simple and efficient means of purifying pancreatic lipase, it requires finely emulsified water-insoluble α-glycerides as substrates, and the liberated fatty acids prevent long-chain β-monoglycerides also produced from isomerizing to α-monoglycerides, which would be poor substrates for mucosal fat re-synthesis Any short-chain β-monoglycerides, however, isomerize and are destroyed

Prof L L M van Deenen (Holland) went on to describe how the unambiguous synthetic work of his laboratory has firmly established the specificities of the phospholipases, which can now safely be used to elucidate the structures of natural lipids Thus it has been shown unequivocally that the plasmalogens and the batyl or chimyl phosphatides are α′-glyceryl ethers, not β-glyceryl compounds as first thought, again, all phospholipases attack phosphatidylglycerol C, yielding a diglyceride and D-α-glycerophosphate

The substrate specificities of several phospholipases have been shown by Dr R M C Dawson (Great Britain) and his colleagues to be matters not only of chemical structures but also of micellar surface charges, which can be measured as electrophoretic mobilities and regulated with suitable counter-ions This can even be demonstrated with the specific phosphatases attacking the polyphosphoinositides, which are virtually water-soluble

The unusual metabolism of these very polar compounds in animal tissues was then discussed by Dr J N Hawthorne (Great Britain) They probably arise from the phosphorylation of monophosphoinositide, which is in turn formed by a unique reaction between cytidine diphosphate diglyceride and free inositol A possible function of the inositol phosphatides may be the transport of divalent cations across mitochondrial membranes

The gaps in our knowledge of the metabolism of plasmalogens were then exposed by Dr E F Hartree (Great Britain), the fatty acid of choline plasmalogen is a major source of energy for mammalian spermatozoa, but little is known about the enzymatic rupture and synthesis of the α′-1-alkenyl ether bond It seems to be formed from a long-chain acyl-coenzyme *A*, yet such compounds can be reduced enzymatically giving free aldehydes which are not incorporated into plasmalogens

At an informal and lively symposium that evening, many examples were given of the great but mysterious physiological importance of the structures of certain fatty acids, which is only partly explicable by their physical properties but also depends on the particular lipids in which they occur.

The conference next examined the digestion and absorption of fat– Prof B Borgstrom (Sweden) explained how triglycerides are emulsified by bile salts and digested by pancreatic lipase to give free fatty acids and β-monoglycerides, this mixture is readily absorbed, helped by the re-synthesis of fat in the mucosa In the absence of bile salts lipase itself catalyses triglyceride synthesis

Dr G H Hubscher (Great Britain) then outlined two other and probably more important processes of mucosal fat re-synthesis, both requiring coenzyme *A* for the acylation of α,β-diglycerides, which arise either directly from β-monoglycerides or by enzymatic dephosphorylation of phosphatidic acids produced by acylation of L-α-glycerophosphate The phosphatic synthesis needs two new co-factors, one thermolabile, the other probably related to carnitine

Quantitative ideas of fat absorption and transport *in vivo* have, according to Dr A M Dawson (Great Britain), been seriously distorted by technical difficulties of measurement It now appears both that free glycerol can be an important source of glycerophosphate for mucosal triglyceride re-synthesis, and that up to a third of the long-chain acids of ingested fat pass into the portal vein in the free state

Drs W M F Leat and T Gillman (Great Britain) then dealt with the absorption, transport and clearance of fat by ruminants, they absorb neutral fat poorly and cannot tolerate it as an intravenous emulsion, but readily absorb free fatty acids which are then kept at a steady level in the plasma by hormonal regulation.

The conference then turned to its second major theme, the physiological significance of lipids in the general economy of animals and bacteria, beginning with a session devoted to large-scale events in living animals

Dr D S Robinson (Great Britain) began by suggesting that only a small amount of fat is supplied to tissues by mammalian blood as free fatty acids, since a large proportion of any available are rapidly converted by the liver into plasma lipoprotein triglycerides, the latter are readily used by the tissues after hydrolysis by lipoprotein lipase, which is probably in the capillary endothelium and is controlled both by the tissues' needs and by the supply of fat

Even in ruminants, said Dr E F Annison (Great Britain), isotope dilution experiments have shown that glucose is the main substrate for respiration *in vivo*, long-chain fatty acids are used anabolically, as in other animals, although acetate is oxidized to some extent

Dr R G Macfarlane (Great Britain) summarized the confused history of theories connecting lipids with blood clotting Two stages in this very complex process still appear to require lipids, even after the elimination of misleading phenomena such as non-specific 'contact activation' and the massive thromboses produced by free fatty acids The lipids' micellar surface charges seem to be more important than their chemical structures

Ruminants have peculiar depot fats because, said Dr A G Garton (Great Britain), all the fatty acids which they absorb arise either by microbial alteration of the dietary lipids or by digestion of the rumen micro-organisms themselves The former process yields short-chain acids from glycerol and galactose, and partially hydrogenated and isomerized long-chain acids, branched-chain acids are derived from bacterial protoplast membranes.

The ruminant's milk fatty acids, on the other hand, have, according to Prof G Peeters (Belgium), been shown by recent experiments *in vivo*, and with perfused isolated udders, to be mostly synthesized from blood acetate, with a small contribution from propionate, long-chain acids, however, can be obtained from the plasma's scarce triglycerides, but will only exchange with its free fatty acids, without net uptake

The next session was concerned with the locations and properties of lipids in the surfaces and internal parts of cells Prof W Bartley (Great Britain) described the lipid compositions of the intracellular organelles of rat liver and brain The fatty acids are characteristic of the lipids rather than of the organelles, except that 'essential' fatty acids are unusually abundant in mitochondrial cardiolipids, which may be functionally important, being the only mitochondrial lipids remaining in oxidatively phosphorylating 'digitonin particles'.

Possible structures of animal cell membranes were then discussed, Drs J A Lucy and J T Dingle (Great Britain) demonstrated that certain lipid mixtures could give electron micrographs showing hexagonal arrays of uniform spherical micelles, on the other hand, Drs. A D Bangham and R Horne (Great Britain) had obtained pictures confirming the more usual idea of a lamellar structure

Dr. M G Macfarlane (Great Britain) then surveyed the lipids of bacterial protoplast membranes, which contain some unique compounds such as the phosphatidyl glyceryl amino-acids and diacyl glyceryl mannose, besides resembling mitochondria both functionally and in being rich in acidic phosphatides Their fatty acids are mostly saturated, but a large proportion have highly branched chains, and hence show physical resemblances to the polyunsaturated acids essential for higher animals

Drs L E and M R Hokin (United States) then described how secretory activity and the turnover of phosphatidic acid labelled with phosphorus-32 in avian pancreas or salt gland are reversibly stimulated by pancreozymin or acetylcholine *in vitro*, when the hormone is removed, the label goes to phosphatidylinositol This may represent the activation and inactivation of a sodium carrier by the conversion of phosphatidylinositol to phosphatidic acid and vice versa

The second evening symposium was devoted to a popular and stimulating discussion of recent progress in the separation and analysis of lipids by chromatographic methods, with perhaps the greatest interest being shown in thin-layer chromatography

Some pathological and endocrinological aspects of lipid metabolism were then examined Dr C R C Heard and Prof B S Platt (Great Britain) reported some deleterious effects of low-protein diets on young animals With the worst diets, even a trace of casein was very beneficial, whereas extra carbohydrate led to obesity, œdema, fatty livers and low glucose tolerance, besides severe regression of the thyroid and, suggestively, of the β-cells of the islets of Langerhans

Dr. K R Rees (Great Britain) then showed how another defect in protein metabolism may be the direct cause of the fatty livers induced by, for example, poisoning with carbon tetrachloride; the poisoned liver converts plasma free fatty acids into triglycerides as usual, but can no longer return them to the plasma in low-density lipoproteins Certain detergents, however, will move this fat into the bloodstream, thus preventing fatty livers

Prof W Fromkel (United States) had found that, *in vitro*, adipose tissue's utilization of glucose for respiration and fat synthesis was greatly and immediately stimulated by insulin, the effect persisting somewhat after the hormone's destruction, while thyroid slices treated with thyroid stimulating hormone oxidized more, not less, glucose when fatty acids were added, and incorporated them into kephalins rather than triglycerides these effects resembled events *in vivo*

Dr G B Ansell (Great Britain) reviewed present knowledge of the effects of electricity and drugs on lipid metabolism in the nervous system, and described some experiments with chlorpromazine It was known to increase the turnover of phosphatidic acid and phosphatidylinositol in brain slices, but decreased that of lecithin, probably by inhibiting the formation of cytidine diphosphate choline

Leucocytes will ingest starch particles by phagocytosis, or, when stimulated by deoxycholate, inulin solutions by pinocytosis Prof M L Karnovsky (United States) reported experiments in which these phenomena, presumably requiring the formation of much new cell membrane and hence expected to stimulate phospholipid metabolism, were indeed accompanied by six-fold increases in the turnover of phosphatidic acid, with smaller increases for other acidic phospholipids

The last afternoon session was devoted to the nervous system Prof R Rossiter (Canada) gave an account of the ability of brain to synthesize phospholipids *in vitro* Preparations from young animals show the usual 'Kennedy pathway', as well as a base-exchange reaction interconverting phosphatidylethanolamine and phosphatidylserine, a decarboxylation of the latter, and an especially rapid synthesis of plasmalogens Phosphatidylinositol is rapidly formed from cytidine diphosphate diglyceride; di- and tri-phosphoinositide are even more actively metabolized.

On the other hand, Dr A N. Davison (Great Britain) and his colleagues have confirmed that the myelin sheathing the larger nerve fibres of the central nervous system does not metabolize in adults, it has a negligible enzyme content, and isotopically labelled cholesterol, cerebrosides, sulphatides, sphingomyelin, ethanolamine plasmalogen, phosphatidyl serine and proteolipid proteins, once laid down in young animals, persist throughout life

Prof R. H. S. Thompson (Great Britain) went on to outline the evidence for a possible explanation of the disappearance of myelin, normally so stable, from the lesions of disseminated sclerosis An observed deficiency of essential fatty acids could cause mitochondrial failure in the metabolically active oligodendroglia, and hence cell lysis with the release of phospholipases, known to occur in brain and to form the myelinolytic lysolecithin, which also lyses cells to release more phospholipase; this autocatalytic process will stop only when the systems removing lysolecithin regain control

Prof L Svennerholm (Sweden) then outlined the complex interrelations between the gangliosides of brain neurones, in connexion with Tay-Sachs disease. The infant victims' brains accumulate excessive quantities of an unusually simple ganglioside, due to a deficiency either of the enzymes normally destroying it or of those which would normally use it for the synthesis of higher gangliosides by attaching further galactose, *N*-acetylgalactosamine and *N*-acetyl-neuraminic acid residues to it

Prof F R N. Gurd (United States) opened the final meeting by demonstrating, from the structure of myoglobin, the specific bonding of 'lipids', such as the non-polar groups of hæm, with the globin's non-polar amino-acid residues, which are collected together away from the protein's polar regions

Dr D. E Green (United States) went on to describe analogous properties of mitochondria, careful extraction with aqueous acetone leaves their protein skeletons intact but abolishes their enzymatic activities, which can then be restored by treatment with aqueous emulsions of the extracted lipids Lecithin will reactivate the dehydrogenases, but both coenzyme *Q* and acidic phosphatides—preferably cardiolipins—are needed for oxidative phosphorylation, which seems to involve stoichiometric reactions between the cytochromes and groups of the lipids' polar 'heads', the hydrophobic 'tails' being attached to the non-polar regions of the protein skeleton.

Taken together with observations by other speakers, including Prof K Bloch, Prof W Bartley and Dr M G Macfarlane, Prof Gurd's and Dr Green's findings suggest one possible aspect of the 'essential' nature of particular fatty acids These acids are prominent in the lipids of the main energy-yielding apparatus of the bacterial, plant or animal cell, perhaps the non-polar regions of certain vital sections of the protein skeleton of this apparatus require specific structures in the hydrophobic 'tails' of the lipids which must be present for full enzymatic activity to be displayed

G. H Sloane-Stanley

CHARACTERIZATION AND USES OF HUMAN DIPLOID CELL STRAINS

A SYMPOSIUM on "The Characterization and Uses of Human Diploid Cell Strains (HDCS)", sponsored by the Permanent Section on Microbiological Standardization of the International Association of Microbiological Societies, was held in Opatija, Yugoslavia, during September 24–26 Ninety-six delegates from 18 countries attended The sessions covered the following topics (1) The management of human diploid cell strains (2) Biochemical, cytogenetic and immunological studies on human diploid cells (3) Virus spectrum of human diploid cells (4) Production of human virus vaccines in human diploid cell strains (5) Results of clinical trials on the use of vaccines prepared in human diploid cell strains

Many laboratories receiving the human diploid cell strains reported their success in propagating the cells and attributed most of their early failures in handling these strains to variations in media constituents The cells showed the classic normal human diploid karyotype until approximately the 40th cell generation

It was reported that, at least for some loci, cultured diploid cells carry and express the genes of their donor The human diploid cell strains retain the donor's chromosomal complement, they also maintain biochemical and immunological properties of the donor cells In a sense these observations are complementary, for they indicate at two structural levels an apparent genetic resemblance between the cultured cells and the somatic tissues of the host

The numerous attempts to isolate latent viruses from these cells have been unsuccessful Dangers from extraneous oncogenic viruses, inherent in the use of primary explants of animal tissue, are largely circumvented in the opinion of many workers when human diploid cell strains are used for vaccine production

Investigations on the virus spectrum of human diploid cell strains indicated their susceptibility to many viruses These strains were thought to be particularly valuable in work with the rhinoviruses which cannot generally be detected in other cell substrates Since different human diploid cell strains vary in their sensitivity to rhinoviruses, it was felt important to use the most sensitive strains

Both live attenuated and killed vaccines for parenteral inoculation or oral administration have been made in human diploid cell strains from poliovirus, rhinovirus, adenovirus, varicella, measles, vaccinia and rabies Following adaptation to human diploid cell strains, all viruses investigated were said to give yields equal to those in other cell systems Investigations with poliovirus showed that they retained their genetic markers when propagated in human diploid cell strains

It was urged that all laboratories using human diploid cell strains for vaccine production limit themselves to a few standardized cell strains, since the use of a well-characterized tissue culture system is as logical and necessary as the use of a well-characterized virus to be propagated in this system

Clinical investigations on a number of virus vaccines are in progress It was reported that an oral poliomyelitis vaccine produced in human diploid cell strains has already been successfully tested in a large-scale field trial and that no untoward reactions have been noted in 7,000 subjects who have received vaccine during the past two years It was also reported that such vaccines proliferated in the gastro-intestinal tract and elicited an antibody response

On the basis of the investigations suggesting the feasibility of large-scale production of virus vaccines in human diploid cells strains, a sub-committee of the conference drafted "Minimum Requirements for Human Diploid Cell Strains to be Used in Vaccine Preparation" These requirements were presented to the symposium participants and adopted at a plenary session

SCIENTIFIC RESEARCH IN NEW ZEALAND

THE report of the Department of Scientific and Industrial Research, New Zealand, for the year ended March 31, 1963*, includes the Minister's statement, the report of the Council, the longer report of the Secretary, to which are attached brief reports from the various Divisions, the Incorporated Research Associations, and on granted-aid research in the Cawthron Institute, Lincoln College, Massey University College of Manawatu, and the Industrial Development Department, University of Canterbury The fifth annual report of the Ross Dependency Research Committee is appended, to which, as to the Divisional reports, a list of publications is attached The Council in its report reiterates the view that a much more comprehensive review of research is needed than was given by the Royal Commission on State Services, but supports the proposal to replace the present Council, which is advisory only to the Department of Scientific and Industrial Research, with a National Research Council responsible for advising the Government on all aspects of research in Government Departments The new Council should be advised by a number of expert committees, but the Department of Scientific and Industrial Research must retain many of the existing expert committees Research and development expenditure in New Zealand in 1961–62 was still only 0 3 per cent of the gross national product or £1 9 per head of the population, the Department's gross expenditure of £2 19 million being 0 163 per cent of the gross national product Staff at March 31, 1963, numbered 1,229, including 455 scientific officers, compared with 1,170 and 442, respectively, the previous year An increase of 60 in the staff has been approved for 1963–64, as well as re-equipment of the Dominion Physical Laboratory over the next three years at an estimated cost of £120,000

---

* New Zealand Report of the Department of Scientific and Industrial Research for the year ended 31 March, 1963 Pp 87 (H 34) (Wellington Government Printer, 1963) 3s

The Council's report also notes the steady improvement in the educational qualifications of the Department's scientific officers, and the present staff now includes 17 with a D Sc degree and 99 with a Ph D The senior research fellowship programme continues to be most successful, and an increase in the number of awards from two to five is recommended Grants to research associations in 1962–63 totalled £169,720, to universities and agricultural colleges £37,070, and to the Antarctic Division £126,607 The highest items in the total expenditure of £2,389,000 are £237,000 on the Dominion Laboratory and £238,000 on the Dominion Physical Laboratory The only other items exceeding £100,000 are £132,000 to the Geological Survey, £154,000 to the Geophysics Division, £114,000 to the Grasslands Division, £105,000 to the Plant Diseases Division, and £137,000 to the Soil Bureau, but £90,000 went to the Crop Research Division

The Secretary's report stresses the value of geochemical prospecting for mineral resources in New Zealand and gives some details of the iron-sand investigations in North Island Field trials are demonstrating the excellent performance, under farm conditions throughout New Zealand, of the new hybrid ryegrass developed by the Grasslands Division over the past fifteen years The Plant Chemistry Division has been seeking to find a culture suitable for bacteria of lucerne, clover and trefoil Two enzyme systems which hydrolyse or decompose sucrose are now being investigated in some New Zealand soils, particularly under introduced pasture With the present-day retreat of the Franz Josef Glacier, the opportunity has been taken to examine the microbiology of a series of soils in process of formation from unweathered glacial detritus Besides investigations on the rate of chemical breakdown, residue and metabolism of demeton methyl, phosphamidon, guthion and dimethoate (Rogor) used to control aphids, a programme of research has been initiated with the view of integrating biological and chemical methods of controlling pests

An Australian method has been applied successfully in the ripening of peaches for canning to prevent loss from brown rot, and field trials have established the considerable scope for mechanical soil fumigation in New Zealand Immediate relief from the chironomid midge in oxidative ponds has been obtained by the judicious use of insecticides, and there seems every prospect of a permanent solution of the problem Reference is also made to the work of the Botany Division in connexion with the control of noxious weeds and on the incompatibility of plants A review has been prepared of the features of the Antarctic ionosphere during calm and disturbed conditions, and the effect of γ-rays and X-rays on certain sugars has been examined with an electron spin resonance spectrometer Five narrow-angle Geiger tube telescopes have been installed at the Institute of Nuclear Sciences to investigate the daily variations in the intensity of cosmic rays coming from outer space, while industrial research has shown that high-grade rayon pulp can be made from *Pinus radiata*, which can be used to manufacture dissolving pulps A simple and effective instrument has been developed for comparing reflexions from opposite surfaces of sheet glass and thus give a measure of its 'waviness' or distorting properties.

TALENT FOR TO-MORROW

A BOW Group pamphlet, *Talent for Tomorrow**, by R Smith and R Eddison, arguing that any policy of reform of higher education must be based both on a thorough understanding of the way in which the present system works and on some attempt to estimate what will be required of it in the future, discusses the problem in the light of higher education as a determining factor in the character and effectiveness of primary and secondary education It is in the universities and colleges that teachers are taught the fundamentals of their profession Such institutions act not only as a vital factor in our economic potential but also as a means of providing a haven for older men to think as well as for younger men to learn Educational policy is not simply a matter for Cabinet discussion and a few crucial decisions at the top it depends on many decisions at many levels, and, while arguing for closer integration of the political machinery at the centre, the pamphlet also insists on the need for considerable devolution in policy making

Surveying in the first of the four chapters of the pamphlet the national need, the Bow Group maintains that the major problem in the next twenty years, given continuing economic growth, will be that of educating men and women to a high enough level, and, allowing some 7–10 per cent places for overseas students, as at present, it estimates that in 1980 some 630,000 places will be required in full-time higher education, including 320,000 in universities These figures compare with 560,000 and 346,000 in the Robbins Report (*Nature*, 200, 925, 1963), and would provide an annual entry of about 180 000 home students, including 72,000 to universities, and about 16,000 overseas students

The present pattern of opportunity is considered in the second chapter, which leans very definitely towards 10,000 as a reasonable maximum size for a university, and stresses the need for careful preparation before institutions are given the right to confer degrees It suggests that three of the colleges of advanced technology should be selected for promotion, providing, with the Manchester College of Science and Technology, the Imperial College of Science and Technology, and the new University of Strathclyde, six technological universities which could lead the way in trying out new ideas in technological education The remaining colleges of advanced technology would keep their present status, but no immediate change in the status of the teacher training colleges is proposed By 1980 the technological universities would have some 70,000 students, and there would be 170,000 in the regional colleges of technology and commerce and 140,000 in the professional and teacher training colleges In the 1970's the opportunity to found another 6–10 universities would be welcomed as well as more professional colleges and colleges of technology Emphasis is laid on the danger of drawing staff from secondary schools in this expansion and on the importance of promoting greater mobility of employment between higher education and other professions, including civil servants and industrial management Lower staff ratios in the universities seem inevitable but could be offset by employing more administrative, clerical and technical staff, by providing better library facilities and by a more imaginative approach to technical teaching aids, especially television The final chapter considers the financial expenditure involved as a national investment, urging that Britain must revise her scale of priorities where education, and especially higher education, is concerned, and be prepared to spend 1 5 per cent of her national income on higher education. At this rate there would be no difficulty in meeting the cost of the expansion plans advocated in the pamphlet

STRUCTURE OF LIQUID SILICATE SLAGS

THE investigation of steel-making slags goes back probably to the 1880's when Fouqué and Lévy experimented with synthetic minerals made from fusion of pure oxides at controlled temperatures. Later, Doelter, Vogt and Tammann carried the work a stage further in their investigations of silicate phase-diagrams. The work of Rankin, Wright and Bowen at the Geophysical Laboratory in Washington, on binary and ternary silicate phase-diagrams, is well known and contributed much to our knowledge of composition and structure of metallurgical slags. It was otherwise, however, with liquid silicates, the 'magma' from which minerals in solid slags crystallized out. This complex problem appears to have been investigated by Vogt in 1902, but his conclusion that the crystalline minerals found microscopically in a slag represented those fundamental to the mother-liquor was later disproved by Schenck in the 1930's. Schenck's thesis was that knowledge of the crystallized compounds found in slags was of little value as a guide to their behaviour in the liquid state. The concentration of oxides of lime, iron and silica in a slag gives no clear indication of its chemical properties because of the ramified chemical changes occurring when they react to form a solution. Later work by Sauerwald and Neuendorff in 1925 demonstrated the ionic nature of liquid silicates by causing deposition of metallic iron from an iron-silicate melt by electrolysis.

In a stimulating article by J. B. Henderson of the Department of Physical Chemistry, Central Research Laboratories, the Broken Hill Proprietary Co., Ltd., Australia (*Technical Bulletin*, 7, No. 2; July 1963), the present-day theories of the constitution of liquid silicate slags are reviewed and their limitations clearly defined. Although brief, this article gives an indication of the technique now being applied in contemporary studies in the elucidation of the structure of the more complex silicate slags. Henderson comments: "Until recently little interest has been evinced in these liquids. There are two reasons for this: in the first place, it has been exceedingly difficult to study these melts under well-controlled conditions in the laboratory, owing to the lack of good refractories and the tiresome techniques involved. In the second, these liquids are themselves so complex that theoretical prediction of their structure has so far proved impossible".

Such knowledge as we have to-day of liquid silicates is essentially founded on the X-ray results of researches by Zachariasen, Bragg and Biscoe and Warren (see F. D. Richardson, "Oxide Slags—A Survey of Our Present Knowledge", *The Physical Chemistry of Steel-Making*, 55, John Wiley and Sons, and Technology Press, New York, 1958). In his article Mr. Henderson reviews some of the modern ideas of liquid silicate structure and shows how such models are derived by reference to "measurements of self-diffusion coefficients". He contrasts by schematic representation (after Richardson) the silicate tetrahedron which is fundamental and the molten silica pattern in which the structure is distorted. The addition of metal oxides, such as lime or magnesia, to the molten silica produces profound structural changes which are indicative of the electrochemical forces at work.

The complexity of this problem of the constitution of liquid silicates is here clearly demonstrated. Present-day theories may help to explain 'qualitatively' the nature of binary melts, but 'quantitatively' they cannot be described nor can the structure of melts of more complicated compositions be predicted. These demand individual investigation and many different types of measurement are needed. The approaches to such research now in train in the Broken Hill Proprietary Company's Laboratories include X-ray, neutron and electron diffraction, absorption spectroscopy, electrolysis, ultra-sonic absorption, density, cryoscopy, refractive index and vapour pressure.

H. B. MILNER

FIBRE OPTICAL PROPERTIES OF ULEXITE

By MRS. E. J. WEICHEL-MOORE and DR. R. J. POTTER

Thomas J. Watson Research Center, Yorktown Heights, New York

THE optical fibre bundle, now a commercially available optical component, requires very high precision in manufacture. It is essential that the optical fibres be assembled in a carefully controlled array such that the position of each fibre with respect to the others is maintained. In many cases, there are hundreds of millions of individual fibres in a given bundle. The manufacture, insulation and assembly of optical fibres are major technological problems which have been overcome by a number of manufacturers.

The early published work on fibre optics by Baird[1], Hansell[2], and Lamm[3] described devices for transmitting images with bundles of bare glass fibres.

In the early 1950's, fibre optics was essentially rediscovered by A. C. S. van Heel[4,5], H. H. Hopkins[6] and Brian O'Brien[7]. Their work is important in the development of the technology. They realized the need for optical insulation, that is, low index cladding between the fibre cores in a close-packed structure.

Since that time, much has been published on the properties of clad optical fibres and the applications of clad fibre bundles. It is significant, however, to note that virtually no important application of fibre optics without cladding has survived. Actually, the technique of assembling and drawing glass fibre bundles was developed by glassmakers in Palestine[8] in the first century B.C. They assembled fibres of coloured glass in the form of a portrait, fused the fibres together, and drew the resulting rod to reduce the portrait in size. The rods were then cut into cross-sections, polished, and pierced to be used as beads. We thank Dr. Dietrich von Bothmer, curator of the Greek and Roman Department of the Metropolitan Museum of Art in New York City, for his co-operation in affording several of these ancient beads for microscopic examination; they were found to be remarkably well preserved. The glasses of which the beads were made are mostly opaque in the bead thickness of approximately $\frac{1}{8}$ in. × $\frac{1}{4}$ in. The fibre structure was eliminated in the

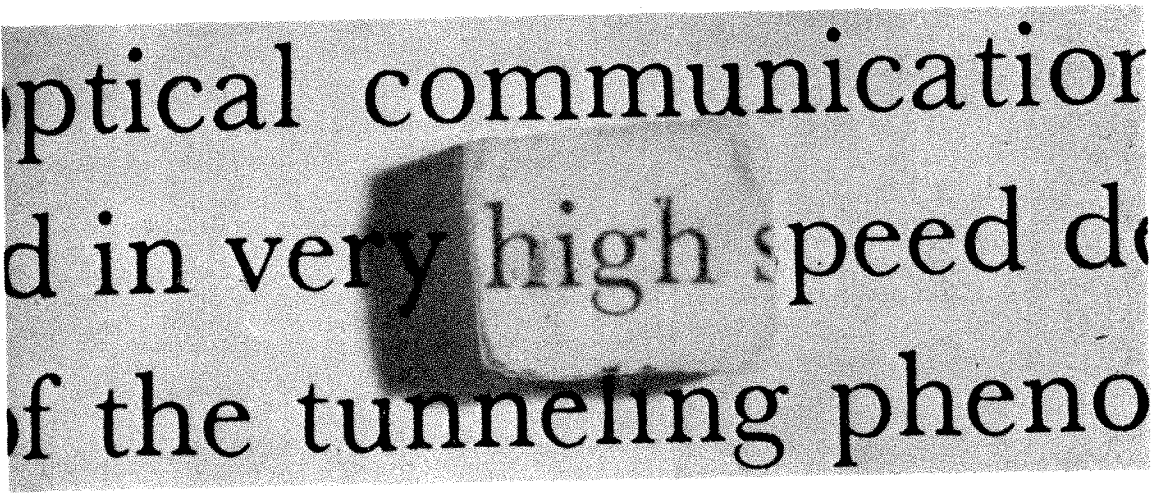

Fig. 1. Image transfer of ulexite fibre bundle

process of fusion so that the final product is not fibre optics, although the fabrication process is presumably essentially the same as the modern method.

With all due respect to the ancient and modern technologies, the purpose of this article is to describe a material known as 'ulexite', found in Nature, which has precisely the same optical properties as a man-made optical fibre bundle. Nature has found another way of solving the cladding problem and has been equally successful in solving the orientation problem. Ulexite fibre bundles are capable of good resolution and exhibit little 'cross-talk'.

Ulexite is a fibrous mineral with the chemical composition, $NaCaB_5O_9{\cdot}8H_2O$ (ref. 9). Ordinarily, the fibres mat together in an aggregate resembling a cotton ball. However, a variety of ulexite is found at Boron, California, in which the fibres are oriented in parallel bundles. Much of the material is pearly and translucent, but some is transparent and of optical quality, yielding samples of 'natural fibre optics'. A small bundle of ulexite, approximately 45 mm in thickness, has been cut and polished perpendicular to the fibre axes; it is able to transmit an image with remarkable clarity, as shown in Fig. 1.

The existence of this variety of ulexite and its fibre optical properties have been known for several years[10], but the phenomenon has not been described in detail. The apparent lack of a low refractive index cladding on the fibres might cause one to believe that the numerical aperture and resolution would be low and subject to the same problems which existed in the early fibre bundles. In fact, however, ulexite has a respectable numerical aperture of $\sim 0{\cdot}3$ and a resolution in excess of 10 lines/mm. In essence, the fibres are cladded because of the random optical orientations of nearest neighbours.

The mineral is triclinic[9], elongated on the *c* axis. Fig. 2 is a photomicrograph of a ulexite fibre bundle taken between crossed polarizers at a magnification of fifty. The adjoining 0·001-in. scale was taken at the same magnification. As the photograph shows, there is tremendous variation in the size and shape of the fibres. Optically, the crystals are biaxial positive[11]. The orientation of the fibres around the *c* axis is completely random, as shown by the variation in extinction between crossed polarizers. X-ray photographs have been taken by Takeda and Donnay[12] of a sliver of the fibre bundle. Their rotation photographs, taken about the fibre axis, show that the fibres are perfectly parallel along the *c* direction. It would be interesting to ascertain the growth conditions which led to such perfect orientation.

According to Larsen and Berman[13], later confirmed by Murdoch[11], the refractive indices of ulexite are $\alpha = 1{\cdot}491$, $\beta = 1{\cdot}504$, $\gamma = 1{\cdot}520$. The intermediate index, β, shows some variation in orientation with respect to the *c*, or fibre, direction. When $y \wedge c = 0^\circ$, β coincides with the fibre axis and the limiting refractive indices in the fibre cross-section are α and γ.

Since the orientation of the fibres is random about the fibre axis, it is possible for the γ direction of a given fibre to be adjacent to the α or α′ direction of a neighbouring fibre; that is, a fibre boundary separates a high- and low-index material. The maximum possible index difference is $\gamma - \alpha = 0{\cdot}029$. Using this value in the expression for the numerical aperture of a perfect, circular, non-birefringent fibre, we calculate a meridional numerical aperture of 0·30. This corresponds to an angular aperture in air of 17·5°.

Actually, the numerical aperture will vary from fibre to fibre depending on the mutual orientations of the high and low refractive index directions at the fibre boundaries. Moreover, the numerical aperture will vary with direction in a single cross-section, since the high index direction, γ,

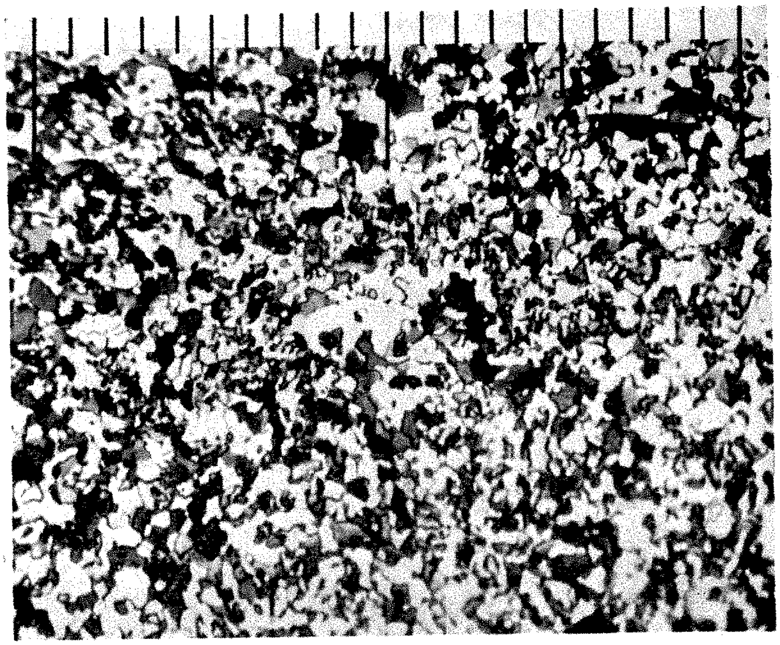

Fig. 2. Fibre cross-section of ulexite, crossed polarizers (× 50; 0·001 in. scale)

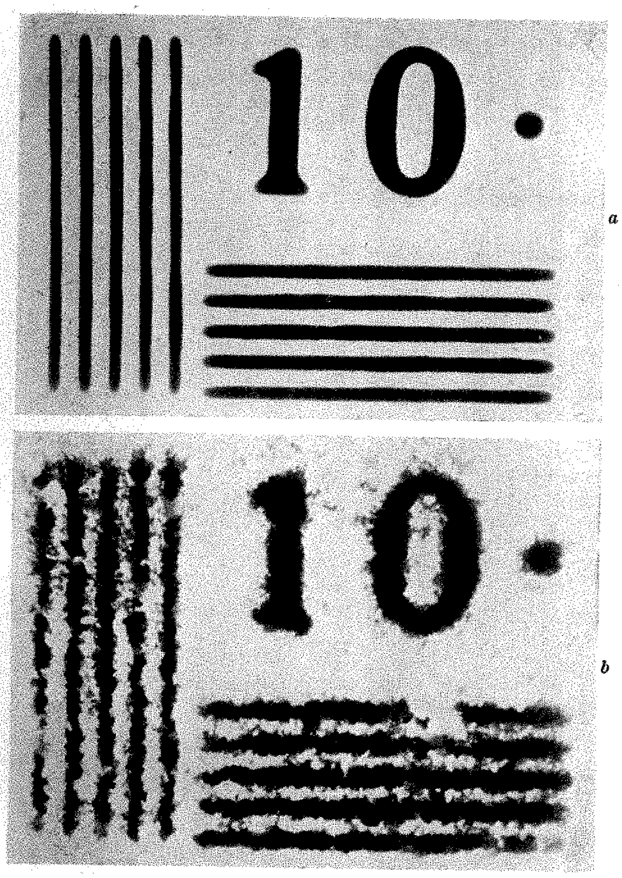

Fig. 3. *a*, National Bureau of Standards, 10 lines/mm (× *c*. 15); *b*, image transfer of National Bureau of Standards, 10 lines/mm by ulexite fibre bundle (× *c*. 15)

can be clad by a lower α or α′ direction, but the α direction cannot be clad by a neighbouring fibre, since there is no lower index available. The numerical aperture of the bundle is a statistical average of the numerical apertures of the individual fibres.

The rays associated with the unclad α direction will always leak into the neighbouring fibre and will thus be unavailable for image transmission in the parent fibre. Rays in higher index directions which are not appropriately clad by a neighbouring fibre will be similarly lost. This can be clearly seen by illuminating the fibre bundle with linearly polarized light and rotating either the polarizer or the sample. The transmission of each fibre varies with respect to its orientation relative to the polarizer, that is, with index direction.

In unpolarized light, the overall transmission of each fibre and the cross-talk between neighbours depend on the number of rays which are appropriately reflected at the fibre boundaries. Because of the random core to cladding index difference between the limits 0–0·029, there will be variations both in the transmission of individual fibres and in the cross-talk between neighbours. These effects are shown in Fig. 3*a*.

The angular aperture of the ulexite bundle shown in Fig. 1 was measured on an Eichner goniometer. As in commercial fibre optics, when one observes an image on the end of the bundle, the transmitted image begins to blur as one exceeds the meridional numerical aperture. The numerical aperture of ulexite was measured by observing the angle at which the transmitted image began to blur. A subjective judgment had to be made; but the measurements were reproducible to ± 1°. The technique was verified using a glass fibre bundle of known numerical aperture and experimentally determining the angular aperture. In this case, of course, the angular aperture was as predicted. The experimental measurement of 18° ± 1° for ulexite compares remarkably well with the theoretical meridional angular aperture of 17·5°. Since the fibres are highly irregular in shape, skew rays probably play an important part in image transmission and influence the average numerical aperture. Because of the skew rays[14], the effective numerical aperture of a circular fibre bundle has been shown to be larger than that predicted by the meridional approximation.

A photomicrograph of National Bureau of Standards resolution chart with 10 lines/mm is shown in Fig. 3*a*. The photograph was taken at 15 times magnification. In Fig. 3*b*, the chart was photographed through the ulexite fibre bundle which was approximately 45 mm thick; the chart is just resolved. Variation in transmission of the different fibres is evident from the photomicrograph, and, as one would expect, some of the fibres do not transmit at all because they are, in fact, not fibre cores but, rather, fibre cladding.

Although one cannot establish a 'fibre diameter', as one would in a commercial fibre bundle, the resolving power of ulexite is measurable, and the numerical aperture is both explicable in terms of optical properties of the material and capable of experimental verification. The discovery and study of ulexite show that it is possible to find in Nature a device almost as good as a man-made fibre bundle.

RELATIONSHIP BETWEEN REFRACTIVE INDEX AND CONCENTRATION OF SOLUTIONS

By F. A. GLOVER and J. D. S. GOULDEN

National Institute for Research in Dairying, Shinfield, Reading

IT is frequently pointed out in light-scattering and other studies that the refractive index of a solution increases linearly with concentration, only when concentration is expressed in terms of weight of solute per unit volume of solution, that is, w/v units[1,2]. In many analytical applications of refractive index measurements, concentrations are normally expressed in terms of weight of solute per unit weight of solution, that is, w/w units, and conversion into w/v units requires a knowledge of the density of each sample. No theoretical justification for the choice of w/v units rather than w/w units of concentration appears to have been published although these relationships can readily be deduced.

Consider a beam of radiation traversing a unit cube of solution, as shown in Fig. 1. The volumes occupied by the solvent and solute molecules, after any interactions during dissolution have occurred, are V_1 and V_2 respectively.

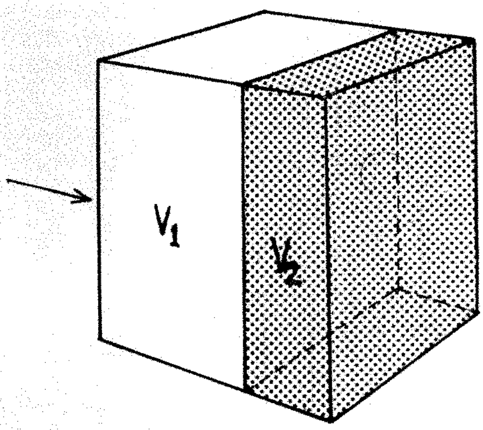

Fig. 1

If at any given temperature the velocities of light in vacuum, solvent, solute and solution are u_0, u_1, u_2 and u_3 respectively, the refractive indices of the solvent, solute and solution are given by

$$n_1 = \frac{u_0}{u_1}, \quad n_2 = \frac{u_0}{u_2}, \quad n_3 = \frac{u_0}{u_3} \qquad (1)$$

In the unit cube the optical path lengths in the solvent and in the solute are numerically equal to V_1 and V_2.

Time taken for light to pass through the solution = time through solvent + time through solute

$$= \frac{V_1}{u_1} + \frac{V_2}{u_2}$$

Velocity of light in the solution is therefore:

$$u_3 = \frac{V_1 + V_2}{V_1/u_1 + V_2/u_2}$$

Hence:

$$n_3 = \frac{u_0(V_1/u_1 + V_2/u_2)}{V_1 + V_2}$$

Using (1) to eliminate u_0, u_1 and u_2:

$$n_3 = \frac{n_1 V_1 + n_2 V_2}{V_1 + V_2}$$

or:

$$n_3 = \frac{V_2(n_2 - n_1)}{V_1 + V_2} + n_1 \qquad (2)$$

If the w/v solute concentration is c_v and the density of the solute in the dissolved state is ρ_2 at the same temperature at which the refractive indices are measured:

$$c_v = \frac{\rho_2 V_2}{V_1 + V_2}$$

Substitution in equation (2) gives:

$$n_3 = \frac{c_v}{\rho_2}(n_2 - n_1) + n$$

or:

$$\Delta n = n_3 - n_1 = \frac{c_v}{\rho_2}(n_2 - n_1) \qquad (3)$$

In the case of w/w concentration units, the density of the solvent ρ_1 must be introduced, so that:

$$c_w = \frac{V_2\rho_2}{V_1\rho_1 + V_2\rho_2}$$

and

$$V_1 = \frac{V_2\rho_2(1 - c_w)}{c_w\rho_1}$$

Substitution for V_1 in (2) and rearranging gives:

$$n_3 = c_w\left(\frac{\rho_1}{\rho_2}\right)(n_2 - n_1)\left[\frac{1}{1 - c_w(1 - \rho_1/\rho_2)}\right] + n_1$$

or

$$\Delta n = c_w\left(\frac{\rho_1}{\rho_2}\right)(n_2 - n_1)\left[1 + c_w\left(1 - \frac{\rho_1}{\rho_2}\right) + c_w^2\left(1 - \frac{\rho_1}{\rho_2}\right)^2\right] \qquad (4)$$

Thus equation (3) predicts a linear relationship of slope $(n_2 - n_1)/\rho_2$ for refractive index increment against concentration in w/v units, whereas equation (4) shows that a curvilinear relationship must hold when w/w units are used.

As shown in Fig. 2, the published data for sucrose[3] confirm these calculations and similar results have also been obtained by Goulden[4] with condensed milk.

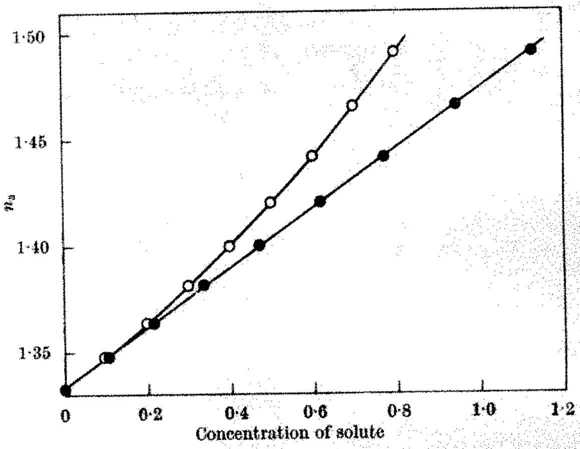

Fig. 2. Refractive index of sucrose solutions n_3) against solute concentration in g/g –○–○–○–, g/ml. –●–●–●–. Wave-length = 0·589 μm; temperature, 20° C

Both equations (3) and (4) contain the density (ρ_2) and the refractive index (n_2) of the solute in solution as distinct from their values in the liquid or solid state, so that neither n_2 nor ρ_2 can be independently evaluated from the variation of refractive index with concentration. In cases such as some protein solutions where linear relationships between density and c_v have been established[5], ρ_2 can be independently evaluated from density measurements and used in conjunction with equation (3) to evaluate n_2. For solutions of strong electrolytes and other cases where interactions with the solute molecules lead to changes in either n_2 or ρ_2 with concentration, deviations will occur from the linear relationship of equation (3).

We thank Dr. R. A. Gibbons for preliminary discussion which led to the mathematical analysis.

A RAPID METHOD FOR DETERMINING THE CORROSIVITY OF THE ATMOSPHERE AT ANY LOCATION

By D. P. DOYLE and HUGH P. GODARD

Aluminium Laboratories, Ltd., Kingston, Ontario

THE use of Sample's 'wire-on-bolt' test to measure galvanic corrosion of metals in the atmosphere has been described[1-3]. This article indicates how the test can be adapted to provide a numerical assessment of corrosivity of the atmosphere in a period as short as three months, as compared with several years required in conventional atmospheric exposure tests.

Two instances where numerical assessment of corrosivity of the atmosphere would be very valuable are when metallic structures are planned for locations where the corrosivity of the atmosphere to the metal involved is unknown, but suspected to be severe, and when metals must be stock-piled in similar circumstances. In the first case, the availability of corrosivity data at an early date permits proper choice of alloy and thickness of sections or sheet, adoption of suitable protective measures if needed, and settlement on design which will ensure as long a life as desired for the structure. In the second instance, the stock-piled metal may be given suitable protective treatments to combat corrosivity of the degree indicated by the test.

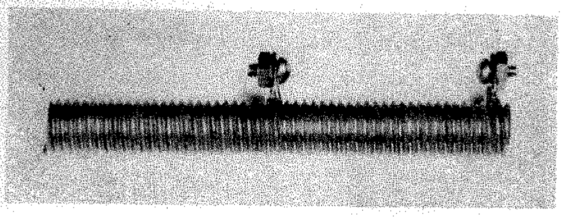

Fig. 1. 'Wire-on-bolt' test specimen

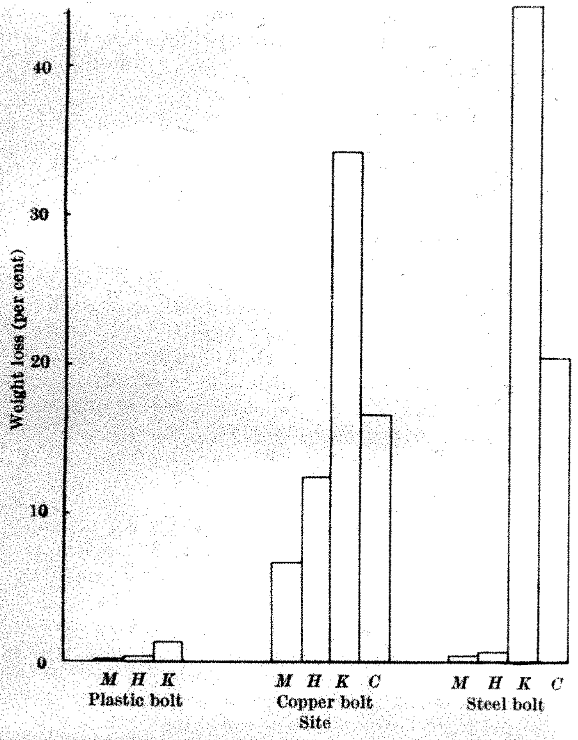

Fig. 2. Weight loss of 0·020-in. diam. 1*S* alloy wire from 'wire-on-bolt' samples exposed for three months at four different sites
M, Montreal; *H*, Halifax—industrial atmosphere. *K*, Kure Beach, N.C.; *C*, Chebucto Head, N.S.—marine atmosphere

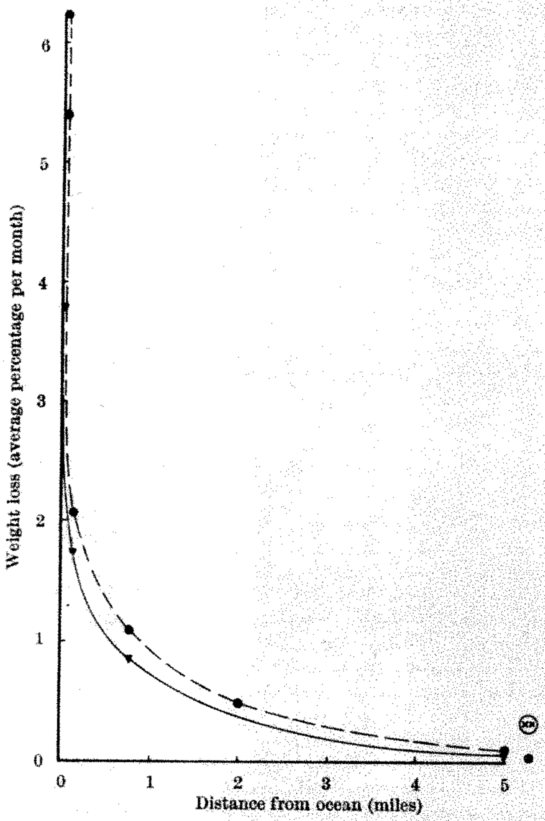

Fig. 3. Graph showing the drop in corrosivity with distance from the ocean at a coastal area of North Carolina, measured by the amount of attack on 2*S* alloy 0·035 in. diam. Aluminium wire wound on mild steel and copper bolts
●, Copper bolt used; ▼, mild steel bolt used; ×, Kingston, Ontario, value—steel bolt (no marine influence); × ×, Montreal, Quebec, value—steel bolt (industrial atmosphere)

In using the test for aluminium, a short length (about 36 in.) of thin (0·035 in. diam.) wire, wound tightly in the threads of a bolt (0·5 in. diam.) or a more cathodic material, is very sensitive to changes in the corrosivity of the atmosphere. The extent of corrosion is assessed by exposing the test piece for three months in the atmosphere being rated, and determining the loss in weight of the aluminium wire. The bolt may be steel, copper or other material the influence of which on the corrosion rate of aluminium is known.

By exposing similar specimens in areas where the performance of aluminium is known and comparing the results the corrosivity of the new location can be judged.

A typical 'wire-on-bolt' test specimen is shown in Fig. 1. The ends of the wire are bolted to 'spade' lugs driven into a snugly fitting hole in the bolt and the connexions are protected from the weather by paint.

Prior to assembly, the aluminium wire is weighed to 0·1 mg. After exposure, the wire is unfastened from the bolt, the corrosion products removed, and the wire re-weighed. The corrosion products are removed by a

30-min immersion of the wire in a hot solution of chromic and phosphoric acids (A.S.T.M.–*B*137–45). A correction is applied for the very small loss of weight during cleaning; this is determined on a similar length of new wire which is treated at the same time.

Comparison of two industrial and two marine atmospheres. Fig. 2 shows the results of an experiment carried out at two industrial and at two marine atmospheres, which demonstrates the relative corrosivity of these atmospheres towards one another, as well as the influence of the bolt material used. It is seen that: (*a*) A copper bolt promoted a high rate of attack on the aluminium wire, but did not alter the relative order of attack, at the four sites, from that which was found for a plastic bolt. Because it is more sensitive, the aluminium–copper couple is preferred. (*b*) A steel bolt promoted a high rate of attack on the aluminium wire, when exposed to a marine atmosphere, and was comparable to copper, but did not do so in an industrial atmosphere. For this reason the aluminium–steel couple may be used to distinguish between marine and industrial atmospheres.

Corrosivity of a marine atmosphere versus distance from shore. Fig. 3 shows the results of an experiment carried out to determine to what distance from the coast the marine corrosive influence is present in the atmosphere. It can be seen that the relative corrosivity drops off very rapidly with distance from the ocean-front. At five miles distance the corrosivity is as low as that of the mild semi-rural inland atmosphere at Kingston, Ontario.

While the examples given here relate to aluminium, other metal pairs could be used for investigating the corrosivity of an atmosphere to any particular metal in wire form which can be paired to a more cathodic metal in bolt form.

Once sufficient data have been accumulated with the 'wire-on-bolt' test it will be possible to dispense with the controls recommended for simultaneous exposure in areas of known performance.

FALSE POSITIVE DIRECT COOMBS TESTS FOLLOWING TOTAL-BODY X-IRRADIATION OF MICE

By OSCAR GARFEIN, NANCY TREACY* and JOHN G. GORMAN*

Department of Pathology, Columbia University, College of Physicians and Surgeons, New York, and Blood Bank, Presbyterian Hospital, New York

NOSSAL *et al.*[1–3] have shown that acquired immunological tolerance can be destroyed by sub-lethal whole-body X-irradiation. If the immunological mechanisms subserving acquired tolerance and natural tolerance are similar, then natural tolerance to auto-antigens may also be destroyed or altered to some extent by treating normal animals with X-ray[4]. To test this hypothesis we treated *A/JAX* and *CBA/JAX* male and female mice with sub-lethal whole body X-irradiation delivered in various dose schedules, and examined serial blood samples from these animals with a direct Coombs test, looking for an auto-immunization to red blood-cell antigens as an indication of breakdown of natural tolerance.

Five test groups were irradiated according to the method described here to examine the effect that fractionation in delivery of a 500-r. dose of X-ray might have on the development of auto-immunity. Group 1*X* received the total dose of X-ray in one exposure; group 2*X* received half of the total dose at one time and received the remaining 250 r. (or 200 r. in the case of the *A/JAX* males) one week later; group 4*X* received one-quarter of the total dose, four times, at weekly intervals; and group 8*X* received one-eighth of the total dose on eight separate occasions, with three and four days alternating between doses. Group 1*X-SP* received the total dose of X-ray in one exposure and, 7 h after this, received approximately fifty thousand isologous spleen cells intravenously. Following the beginning of a course of X-irradiation, serial direct Coombs tests were performed on all mice at 4–6 day intervals.

Each test group, with the exception of one which received isologous spleen cells after its single dose of X-ray, was composed of 2 *A/JAX* males, 2 *A/JAX* females, 2 *CBA/JAX* males, and 2 *CBA/JAX* females. The group given spleen cells after X-irradiation had the same relative composition as the other groups but was composed of sixteen mice. All *CBA/JAX* males and females, and all *A/JAX* females in all test groups received a total of 500 r. whole-body X-irradiation. The *A/JAX* males in all test groups received a total of 400 r. whole-body X-irradiation.

Mice were irradiated in 'Lucite' boxes in groups of 2 (except 500-r. and 400-r. single dose groups which were irradiated 6 per box). The conditions of X-irradiation were as follows: 184 kVp.: 30 m.amp; target—subject distance (from focus to centre of mouse) 72 cm from each of two tubes (cross-fire technique); dose rate 50 r./min; filtration: 0·28 mm copper, 0·5 mm aluminium; half-value layer = 0·6 mm copper.

Five groups of mice identical in composition to the test groups were used for controls. The sole difference in the handling of the control mice was that, once placed in the 'Lucite' boxes used for holding test animals during X-irradiation, they did not receive X-ray but were kept in these boxes for times equivalent to those required for X-irradiating the test animals.

The direct Coombs tests were performed as follows: The mice were tail bled into normal saline and the cells washed 4 times in normal saline. One drop of a 5 per cent suspension of those cells was then added to one drop of rabbit anti-mouse globulin diluted 1 : 32 with normal saline, incubated at room temperature for 30 min and the tubes centrifuged for 1 min before reading. All results were read both macroscopically and microscopically for agglutination.

With each batch of tests the following controls were done and were required to be satisfactory. Saline controls, substituting one drop of normal saline for the rabbit anti-mouse globulin serum, were run simultaneously on every blood sample. To provide an anti-mouse globulin reagent control a Coombs test was performed on known Coombs positive cells and known Coombs negative cells with each batch of cell samples tested. Coombs positive cells were prepared in the following manner: one volume of a 50 per cent suspension of red cells, obtained from a single non-experimental *A/JAX* or *CBA/JAX* mouse, was washed 4 times with normal saline and coated by incubating for 60 min at 37° C with 2 volumes of a 1 : 4

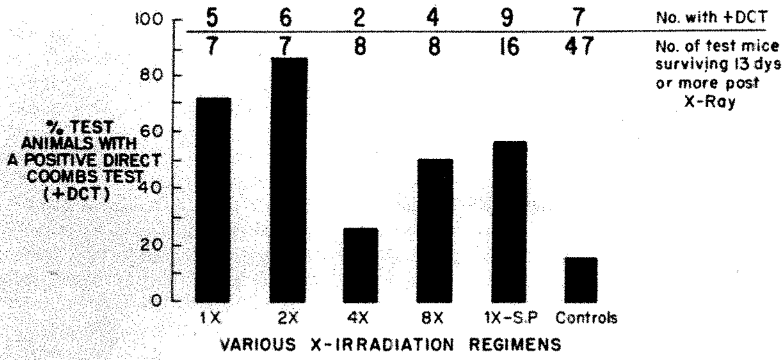

Fig. 1

saline diluted iso-immune mouse serum. This iso-immune serum, used to render both *A/JAX* and *CBA/JAX* red cells Coombs positive, was obtained from *DBA/JAX* mice immunized with *C57/JAX* spleen cells. Coombs negative cells were prepared in the same way except that they were incubated with normal mouse serum. Before use, both coated cells and negative cells were washed 3 times with normal saline and a 5 per cent suspension made. Mouse cells coated in this way gave a strongly positive direct Coombs reaction and cells incubated with normal mouse serum were uniformly negative. Saline controls as described here were also run on these positive and negative control cells. A further negative anti-mouse globulin control consisted of incubating 1 drop of a 5 per cent suspension of 4 times washed *A/JAX* unsensitized cells with 1 drop of the rabbit anti-mouse globulin serum.

The results of the experiment are shown in Fig. 1. 71 per cent of the animals that received a single dose of X-ray developed a positive direct Coombs test. 86 per cent of the animals receiving two equal doses of X-ray became positive, while 25, 50 and 56 per cent of the animals in the remaining three groups developed a positive direct Coombs test. These Coombs tests were transient in most cases, becoming negative spontaneously within seven days. 15 per cent of non-irradiated mice showed a positive direct Coombs test at various times.

In Fig. 2 are indicated the periods in time after the beginning of X-irradiation when the test and control mice that did become positive first showed a positive Coombs test. There were two periods when most of the animals became positive. The first period occurred 14–21 days after the beginning of all X-irradiation procedures. Most of the animals in this group had received single or dual doses of X-ray. The second period occurred at about the 39th day. The bulk of the animals which first showed a positive Coombs test at this time were those animals which had received multiple doses of X-ray. The spleen-protected mice behaved on the whole like the other mice receiving a single dose of X-ray, but tended, as a group, to develop a positive test several days earlier than the mice not receiving spleen cells.

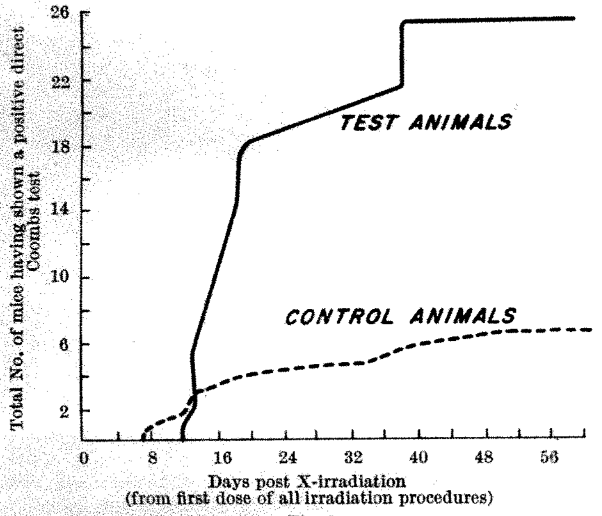

Fig. 2

These results, with special attention to the non-irradiated mice which showed a positive Coombs test, were discussed with Dr. Robert Schwartz of the New England Center Hospital of Boston, Mass. Noting that Muirhead *et al.*[5] have reported positive direct Coombs tests in dogs following phenylhydrazine administration and that Nelken[6] has shown that false positives could occur with human blood samples with high reticulocyte counts, he suggested that this possible source of error in our experiments should be excluded. Such false positive direct Coombs tests associated with reticulocytosis are thought to be due to an anti-iron binding globulin (anti-transferrin) antibody in the Coombs serum reacting with iron binding globulin which is normally present on the surface of reticulocytes[7].

On the basis of this information we repeated, on a much smaller scale, our original experiment and found that of 10 *A/JAX* mice that were given a single dose of 500 r., 8 of 9 that survived 13 days or more developed a 30–50 per cent reticulocytosis and showed a strong positive direct Coombs test when tested with our original Coombs serum. In 5 mice given isologous spleen cells after irradiation, reticulocytosis and false positive Coombs tests were seen as early as 5 days after X-ray. When simultaneous blood samples from these mice were tested with the same Coombs serum absorbed with reticulocytes, negative results in all cases were obtained. We also noted that when Coombs serum unabsorbed with reticulocytes was used, the addition of 1 drop of guinea pig serum (intended as a source of complement) to the test mixture inhibited the false positive agglutination reaction but did not inhibit the positive reaction with our positive control cells coated with iso-antibody. This inhibition is apparently due to the presence of iron binding globulin in guinea pig serum sufficiently similar antigenically to mouse iron binding globulin to inhibit rabbit anti-mouse iron binding globulin antibodies.

To prepare reticulocytes used for absorbing the Coombs serum healthy *A/JAX* mice were given intravenously 0·04 mg phenylhydrazine hydrochloride per g body-weight as a 1 per cent solution in normal saline daily for three days[5]. Three days after the last dose, reticulocyte counts ranged from 30 to 35 per cent and all mice were Coombs positive with unabsorbed Coombs reagent, but were negative when guinea pig serum was added to the reaction and negative with reticulocyte absorbed Coombs serum. In other words, phenylhydrazine produces false positive Coombs tests due to reticulocytosis regularly in mice. Reticulocytes used for absorbing the Coombs reagent were obtained by killing these mice on the fourth day after the last dose of phenylhydrazine.

On checking our non-experimental *A/JAX* mice we found that reticulocyte counts ranged regularly from 10 to 15 per cent. It is probable that occasional reticulocyte levels ranging even higher than this accounted for the few positive Coombs tests seen in our non-irradiated control animals. These levels are considerably higher than earlier published values[8] which still stand as typical of levels being observed at present in reticulocyte counts on *A/JAX* mice at Bar Harbor[9].

It is clear that the positive direct Coombs tests reported here in mice after whole-body irradiation do not indicate the breakdown of natural tolerance to red-cell auto-antigens but rather just reflect the existence of post-irradiation reticulocytosis. In the light of the true nature of these positive Coombs tests it is easy to explain the temporal relationships of the onset of positive tests to the beginning of irradiation. Whole-body X-ray doses of the size that were administered suppress erythropoiesis for 7–10 days[10], after which a brisk reticulocytosis would be expected which might reach its peak in the period of 14–21 days, the period in which we did note most of our positive results. Re-population with unirradiated isologous donor erythroid cells would account for the earlier reticulocytosis and positive Coombs tests seen in mice given spleen cells.

The question of whether natural auto-tolerance is impaired by X-ray, however, remains open for further experimental investigation. It should be noted that in Nossal's experiments[2,3] breakdown of the tolerance mechanism was seen in situations of partial tolerance, where at least a small 'forbidden' auto-immune clone is already established and might quickly grow once free from inhibition by a tolerance mechanism which has been put out of action by irradiation. In cases of complete tolerance as in natural tolerance to red cells, any such emerging 'forbidden' clone would have to be initiated as a new primary response and multiply from a few stem cells[4]. Since the ability to initiate an immune response is severely affected by total-body irradiation[11] and the tolerance mechanism is probably able to repair itself fairly soon after 500-r. X-irradiation[4], it is not too surprising that our test system might fail to detect a breakdown of the tolerance mechanism.

We have demonstrated once again, this time in mice, that high percentages of reticulocytes can cause false positive direct Coombs tests. Coombs reagents by their nature often contain antibodies against serum proteins other than immunoglobulins. If one such non-immune protein happens to be attached to the surface of red cells a false positive Coombs test may be recorded. It is essential that investigators be alert to the fact that positive direct Coombs tests do not always indicate that red cells are coated by immunoglobulins.

This work was supported by grant *U*–1154 of Health Research Council, City of New York.

We thank Dr. Philip Levine and Mr. William Pollack of Ortho Pharmaceutical Co., Raritan, N.J., for the preparation of the rabbit anti-mouse Coombs serum used. We also thank Dr. Douglas Gilmour, Department of Agriculture, University of Cambridge, for a gift of the mouse iso-antibodies used to coat positive control cells and for supervising the absorption of the Coombs serum, and also Dr. Harald H. Rossi and Miss Marlis Wohlfromm, Department of Radiological Research, University of Columbia, for providing irradiation facilities and technical supervision.

TRANSFORMATION OF HÆMOPOIETIC CELLS OF BONE MARROW ALLOGRAFTS INTO LYMPHOCYTES IN X-IRRADIATED DOGS

By I. L. CHERTKOV, M. N. NOVIKOVA, L. S. ROGACHEVA, L. L. SHEPSHELEVICH,
A. S. MAXYMENKO and M. O. RAUSHENBACH

Central Order of Lenin Institute of Hæmatology and Blood Transfusion, Moscow, U.S.S.R.

GOOD therapeutic effects in LD_{95} X-irradiated dogs (600 r.) following transplantation of allogenic bone marrow have already been observed[1]; more than 70 per cent of dogs survived. Examination of the bone marrow action mechanism showed that the graft cells proliferate in the recipient for 2–3 weeks. At this time there was an enlargement in the peripheral blood of the donor's leucocyte count (female in male) and donor's erythrocyte count (by the differential agglutination method with anti-*A* dog's test-serum). After 15–20 days the marrow graft was rejected and simultaneously restoration of the recipient's hæmopoiesis began. Immunological complications were not observed.

In the experiment described here, the dogs X-irradiated with 1,000 r. received bone marrow allograft. The bone marrow was injected intravenously, $5–8 \times 10^9$ nuclear cells on the day after radiation. Bone marrow was removed from the sternum and ribs and suspended in aliquots of '*TC*-199'. The marrow was passed through two layers of gauze. Staining with erythrosine demonstrated that more than 98 per cent of the cells were viable. This was also suggested by the ability of the marrow cells to synthesize DNA (by incorporation of tritiated thymidine).

In these conditions bone marrow transplantation failed in its therapeutic effect; the dogs died 11–15 days after radiation. At this level of irradiation, the white blood cell count invariably fell during 6–7 days. After 2 days there was a considerable fall of all the elements in the bone marrow; only mature myeloid cells could be observed. However, by the fifth to sixth day after irradiation the stem and immature cells appeared, and the number of mature cells fell (Fig. 1). Restoration of the recipient's hæmopoiesis at this time was impossible; moreover, in bone marrow female donor's leucocytes among mature neutrophils were identified, and in peripheral blood by the sixth to eighth day 2–3·5 per cent of the donor's erythrocytes appeared. These results indicated that graft cells had re-populated and differentiated in the normal way. However, after the seventh to eighth day in bone marrow peculiar 'hyperbasophilic' cells were revealed and normal hæmopoiesis stopped. In bone marrow and peripheral blood it was possible to observe hæmocytoblasts transforming into lymphocytes through several transitional forms. The first of them was a hæmocytoblast with basophilic cytoplasm (Fig. 2), and a young laciniate often plicate nucleus. The next form was like a lymphoblast (Fig. 3, left), the nucleus was more mature, chromatin more solid, the nucleoli were distinct. There was a perinuclear zone in these cells. Lymphoblast differentiated into prolymphocyte (Fig. 3, right). The nucleus was round or kidney-shaped; the chromatin more compact. Sometimes remains of nucleoli could be seen, the perinuclear zone more pronounced, basophily usually marginal. That type of cell converted into lymphocyte, at first hyperbasophilic and then normal.

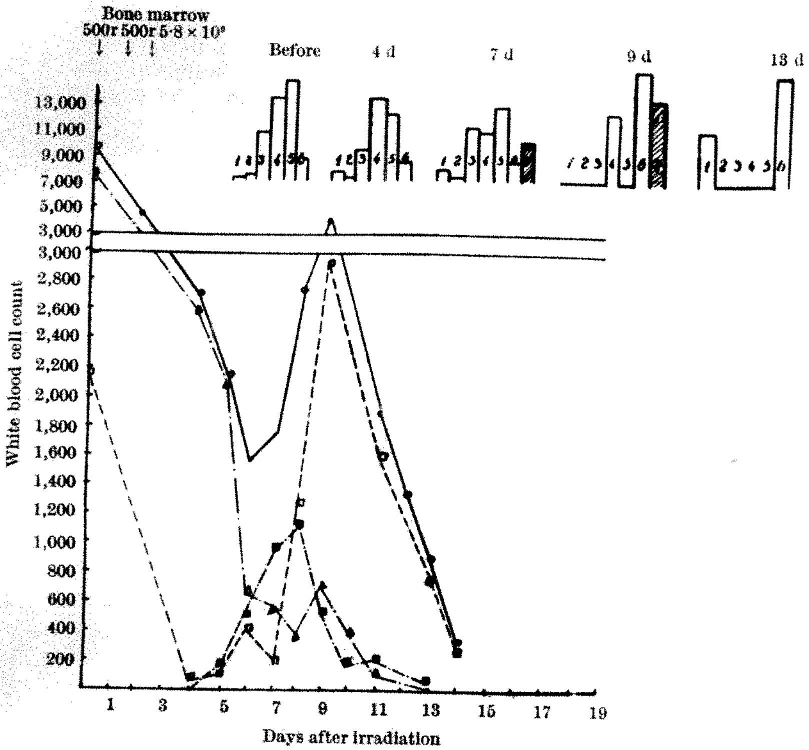

Fig. 1. White blood cell counts and myelograms in a dog irradiated with 1,000 r. for two days. On the day after radiation the dog received allogenic marrow. 1, Reticular cells; 2, stem cells; 3, immature cells of myeloid row; 4, mature cells of myeloid row; 5, erythropoietic row; 6, lymphocytes; 7, hyperbasophilic cells. ○, leucocytes; △, neutrophils; □, lymphocytes; ■, hyperbasophilic cells

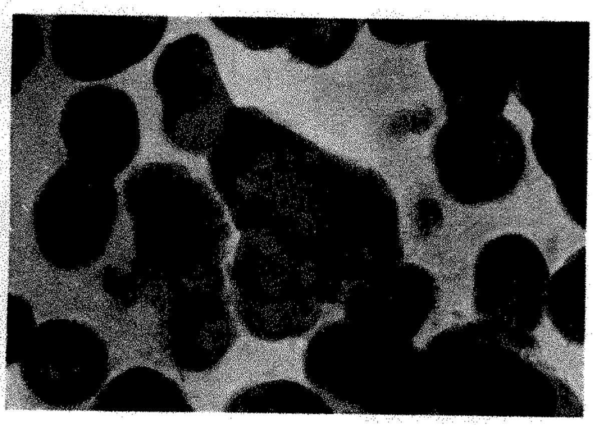

Fig. 2. Hyperbasophilic 'haemocytoblast' from peripheral blood

Consequently, hæmopoiesis was of the lymphoid type. The picture of the peripheral blood reflected this transformation of hæmopoiesis. On the eighth to ninth days the leucocyte count rose greatly (Fig. 1). The rate of proliferation was very high; for 1–2 days the white blood cell count rose 3–4 times (from 400–1,500 to 1,700–4,200 cells/mm^3); moreover, the neutrophil number did not enlarge practically. The effect was caused mainly by hyperbasophilic forms, the number of which was 60–80 per cent from the general leucocyte count on the eighth day. The next day the number of hyperbasophilic cells reduced sharply: simultaneously the lymphocyte count rose. On the following days hyperbasophilic cells disappeared, white blood cells, represented almost only by lymphocytes gradually fell. In bone marrow reticular hyperplasy developed, only reticular cells and lymphocytes were observed (Fig. 1).

Autopsy disclosed massive hæmorrhage in lungs, gastrointestinal tract, and aplasy in lymphoid nodes and bone marrow. Hence supra-lethally X-irradiated dogs had 'takes' of bone marrow allograft which differentiated normally during 3–4 days and then myeloid hæmopoiesis of graft stopped, and hyperbasophilic cells from hæmocytoblast formed. They intensively proliferated for 1–2 days (on the smears figures of amitotic and mitotic division in hyperbasophilic cells were observed); afterwards proliferation stopped and cells transformed into lymphocytes. On the whole this phenomenon is close to that observed in lymph nodes after antigenic stimulation[2]. This suggests that following the strong antigenic stimulation bone marrow allograft transforms into immunologically competent cells which are able to induce the reaction 'graft versus host'. This assumption is confirmed by the fact that transformation does not begin for 3–4 days, this period being necessary for immunization of graft cells. On the other hand, immunological genesis of this graft transformation is confirmed by the similarity of the hyperbasophilic cells described here and of those known as immunologically competent in transplantation immunity[3]. Immunologically inverted genesis of allogenic bone marrow cell is supported by our experiments on screening of dogs' hind-legs during irradiation. No hyperbasophilic cells were seen in the stage of active proliferation of autological bone marrow; hæmopoiesis was normal and the dogs survived.

Special investigations confirmed that hyperbasophilic cells had been formed from the graft's hæmocytoblasts but not from any occasional immunologically competent cells available in the transplant. Intraperitoneal transplantation of 5–15 × 10^9 lymphoid cells derived from donor's spleen and lymph nodes to supralethally X-irradiated dogs was accompanied only by an inconsiderable number of hyperbasophilic cells. These results suggest that hyperbasophilic cells and their derivatives (lymphocytes) are morphological bases of secondary disease and any other reaction of transplantation immunity. Some clinical investigations[4,5] suggest that hæmopoiesis transformation of the type described may occur in bone marrow transplantation in irradiated human beings.

In reactions of 'host versus graft' type, in particular in skin grafts, hyperbasophilic cells are probably formed from stem cells of lymph nodes[3]. It is suggested that some transplantation immunity reactions occur also in disease

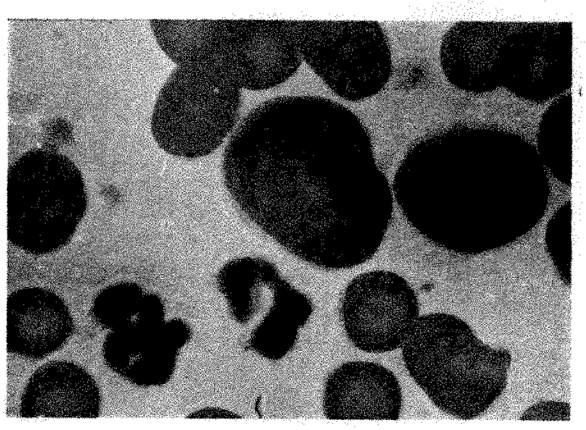

Fig. 3. Hyperbasophilic 'lymphoblast' (left) and 'prolymphocyte' (right) from peripheral blood

accompanied by intensive disintegration of tissues. So we observed the appearance of hyperbasophilic cells in blood of X-irradiated or burnt dogs without any tissue transplantation during the regenerative period.

Transformation of hæmopoietic cells into immunologically competent cells participating in reaction of transplantation immunity is reported here for the first time. Many authors[5–10] consider that the only morphological basis for secondary disease is immunologically competent cells of bone marrow or blood. Our results indicate that secondary disease can be induced by the immunologically competent cells derived from the stem cells of bone marrow, but not by the available immunologically competent cells of bone marrow or blood. In other words, the morphological basis both of protective action of bone marrow transplantation and of immunological complications is identical; that is, stem hæmopoietic cells. Hence it is doubtful whether reducing the number of available immunologically competent cells in the transplant can prevent secondary disease. It is necessary for prophylaxis of secondary disease first of all to prevent transformation of the graft after lymphoid type. The allogenic bone marrow transplantation in supra-lethally irradiated dogs is an excellent model for investigating this problem. The possibility of transformation of hæmopoietic cells into immunologically competent cells following a strong antigenic stimulation suggests that similar processes can also occur in unirradiated hosts. Perhaps this immunological mechanism is significant in pathogenesis of some forms of leukæmia. It is very important to ascertain why in some cases transformation of hæmopoiesis developed very early, and in other cases secondary disease was revealed considerably later if at all[11]. Perhaps the solution of these questions will render possible treatment of the secondary disease, and using of the latter, in leukæmia therapy.

INHIBITORY ASPECTS OF BILE SECRETION

By Dr. TOM HARGREAVES and Prof. GRANT H. LATHE

Departments of Chemical Pathology, St. George's Hospital Medical School, London, S.W.1, and School of Medicine, Leeds

A KNOWLEDGE of the mechanism of bile secretion is probably as important for understanding various types of jaundice, as the mechanism of renal function is the key to understanding kidney disease. Unfortunately, our knowledge of bile secretion is limited due to the inaccessibility of the biliary tract to direct observation. Nevertheless, in recent years some important advances have been made: particularly important is the suggestion that a distinction should be made between the formation of bile and the secretion of substances into it.

Some substances, for example, bilirubin and bile salts, are secreted in bile at a higher concentration than in plasma; others, for example, sodium, potassium and glucose, occur at approximately plasma concentrations. There is also a third class of substances present in bile in lesser amounts than in plasma[1]. Many foreign substances are concentrated in bile; some, like bromsulphthalein, serve as useful agents in assessing liver function, others are used for X-ray examination of bile channels. We propose to use the term 'cholephil' for all endogenous and exogenous substances which are concentrated in the bile.

It appears probable that bile formation involves two simultaneous processes, the formation of a fluid similar to deproteinized plasma and the secretion of cholephilic substances into this fluid. This is suggested by experiments in which the two functions can be dissociated; bile salts increase the flow of bile without increasing the total yield of administered cholephilic substances, for example, bromsulphthalein[2]. Bile production does not depend on the hydrostatic pressure of blood perfusing the liver[3] and must, therefore, depend on a chemical mechanism to provide the energy for bile production. It has been shown that the flow of bile after administration of sodium taurocholate is directly proportional to the taurocholate secretion rate and the electrolyte composition was similar at all rates of secretion[4]. Since the concentrations of the major inorganic anions, chloride and bicarbonate, change very little over the entire range of bile salt secretion rates, the output of these anions must also be directly proportional to the bile salt secretion rate. These observations lend support to the view expressed by Sperber[5] that organic anion secretion (normally bile salt secretion) is actually the primary event in bile formation. It is possible that the movement of inorganic electrolytes and water into the bile may proceed passively and independently along gradients of concentration and electrical potential created by active bile salt secretion into the canalicular lumen, or may be coupled in some manner with active bile salt transport[6]. This suggests that the secretion of high concentrations of other cholephils may enhance bile secretion, as shown for chloral[7]. Cyanide produces a dissociation of the reverse type, reduced bile flow with maintenance of bilirubin and bromsulphthalein secretion[8]. A third type of dissociation, reduction of secretion of cholephilic substances with normal or enhanced bile secretion, can be produced experimentally by administration of phloridzin[8]. Jenner and Smyth[9] found phloridzin, or a product of it, was excreted in the bile at a concentration of up to 0·9 per cent (20 m.equiv./l.).

A number of organic anions, for example, bile pigments, several phthalein dyes, indocyanine green and the bile salts are excreted into the bile in such high concentrations that it is generally assumed that active transport mechanisms must be involved. There is a limiting rate of bromsulphthalein secretion: this mechanism can be saturated by increasing the plasma concentration. Similar saturation phenomena have been described for sodium dehydrocholate, bilirubin and fluorescein[10].

Various reports have suggested that cholephilic substances compete with one another at several stages in their transport from plasma to bile. Dragstedt and Mills[11] examined the rate of clearance of intravenously administered bromsulphthalein; simultaneous administration of bilirubin reduced the rate of clearance by 20–50 per cent. Mendeloff, Kramer, Ingelfinger and Bradley[12] found a reduced clearance of bromsulphthalein from the plasma when dehydrocholic acid was injected and a similar but smaller effect with rose bengal Wheeler, Cranston and Meltzer[13], using dogs, demonstrated that during the constant injection of bromsulphthalein, indocyanine green increased the plasma bromsulphthalein concentration without any reduction of bromsulphthalein excretion Both these results were open to the criticism that bromsulphthalein was being displaced from extra-hepatic tissues, but Andrews and Richards[14] showed that in dogs conjugated bile salts led to a release of bromsulphthalein into the hepatic vein Hunton, Bollman and Hoffman[15] have shown that in unanæsthetized dogs the clearance of bromsulphthalein is reduced by indocyanine green, rose bengal, bilirubin and sodium dehydrocholate In rats bromsulphthalein and indocyanine green each affected the clearance of the other

Rate of clearance cannot be equated with rate of secretion, as the former may be affected by hepatic blood flow and the latter by storage of administered material in the liver It seems possible that for a brief period secretion into the bile might be reduced without clearance being altered, and vice versa Direct measurements of rates of secretion have suggested that competition occurs though usually it has been impossible to say whether this was a primary effect on secretion or secondary to competition for uptake

Investigation of liver uptake has been made by direct observation of the fluorescent substance uranine[16], bilirubin reduced the rate of uranine uptake and its subsequent biliary secretion Fauvert[17] suggested that competition for hepatic uptake exists between bilirubin and bromsulphthalein, the latter being selectively removed Bradley[18] investigated the uptake of bromsulphthalein, as distinct from its secretion, by following the clearance during continuous intravenous administration at increasing rates *In vitro* investigations have shown that biligrafin inhibits the uptake of bromsulphthalein by liver slices[19]

It has been postulated that anionic substances are excreted by a different pathway from cationic substances[20] A number of quaternary ammonium compounds inhibited the biliary excretion of each other, while others were without effect Anions, for example, bromsulphthalein and glycocholate, did not compete with the cations for biliary excretion

In considering the mechanism of competition for a common pathway of secretion into the bile, account must be taken of chemical alterations of the secreted substance Thus bilirubin is secreted in the bile as a diglucuronide, since animals in which the conjugating mechanism is defective cannot excrete bilirubin but can excrete injected bilirubin glucuronide[21], conjugation is essential for secretion of bilirubin In contrast to bilirubin, bromsulphthalein can be excreted unchanged, but most of the injected pigment appears in the bile as a conjugate of glutathione[13] In a third category are those cholephils like indocyanine green[13] and rose bengal[18] which are secreted into the bile without chemical alteration

Other examples of cholephils competing for excretion in the bile are the retention of bilirubin[22] and bromsulphthalein[23] following bunamiodyl administration, and bilirubin retention in the new-born following novobiocin administration[24]

We examined the reduction of bile secretion of one cholephilic substance by another as it seemed possible that this investigation might help to define the biochemical nature of the secretory mechanism We are now reporting the inhibitory effect of a number of cholephilic substances on *in vitro* glucuronide synthesizing systems, and on the *in vivo* secretion of two cholephilic substances, bilirubin glucuronide and indocyanine green

The rate of bilirubin glucuronide formation was determined in rat liver slices, and rat and rabbit liver homogenates, by the method of Lathe and Walker[25] *o*-Aminophenol conjugation was measured by the method of Stephenson and Dutton[26] In the homogenate experiments uridine diphosphate glucuronic acid, Sigma Grade (Sigma Chemical Co), was added in a final concentration of 0 3 m mole Conjugated bilirubin in liver slices was determined according to Hargreaves[27] Glucose-6-phosphatase was estimated by the method of de Duve, Pressman, Gianetto, Wattiaux and Appelmans[28], the hexobarbitone metabolizing enzyme was determined by the method of Cooper and Brodie[29]

The secretion of substances in the bile was investigated in male Wistar rats, anæsthetized with veterinary 'Nembutal' (Abbott), in whom the bile duct was cannulated[30] Bile was collected over 10-min intervals Administered substances were given intravenously Conjugated bilirubin was given as diluted human bile collected post-operatively from a patient with a T-tube in the common bile-duct Norethandrolone was administered in propylene glycol which was found to have no effect on dye or pigment excretion Conjugated bilirubin was determined by the method of Lathe and Walker[25] Indocyanine green was estimated by diluting the bile 1 to 10 or 1 to 100 with water and reading against an appropriate blank at 805 mμ in a spectrophotometer (Unicam *SP* 600)

In vitro *effect of cholephils on formation of glucuronides* Increasing concentrations of cholephilic substances were added to rabbit liver homogenates in order to determine the approximate concentration at which 50 per cent inhibition of bilirubin and of *o*-aminophenol conjugation occurred

Table 1 CONCENTRATIONS REQUIRED TO PRODUCE 50 PER CENT INHIBITION OF MICROSOMAL ENZYMES IN RABBIT LIVER HOMOGENATE

Inhibitor $10^4 \times$ conc (M)	Glucuronyl transferase		Glucose-6-phosphatase
	o-Aminophenol	Bilirubin	
Novobiocin	1	2	50
Bunamiodyl	3	2	>100
Norethandrolone	>100	8	>100
Methicillin	20	30	>100
Bromsulphthalein	< 0 1	2	6
Indocyanine green	3	5	90
Rose bengal	0 6	2	40
Fluorescein	8	—	5
Chloral	50	>100	70
Phenolphthalein	0 2	0 3	40
Phenolphthalein glucuronide	4	0 6	>100

The results of the experiments of this type have been summarized in Table 1 All but methicillin, chloral and norethandrolone inhibited glycuronyl transferase at concentrations of less than 1 m mole As the enzyme conjugating substances with glucuronic acid occurs in the microsomes, two other microsomal enzymes were tested The results with glucose-6-phosphatase are given in Table 1 The enzyme metabolizing hexobarbitone was examined in the presence of four cholephilic substances The rate of hexobarbitone metabolism was inhibited 41 per cent by 0 1 m mole bunamiodyl, 27 per cent by 0 1 m mole indocyanine green and 33 per cent by 1 m mole sodium deoxycholate, 10 m mole methicillin had a negligible effect on this enzyme

In vivo *effect of cholephils on secretion into the bile* Figs 1 and 2 show the rise and fall of bilirubin glucuronide and indocyanine green respectively in rat bile following intravenous injection, alone and with the simultaneous injection of novobiocin The results of 27 experiments of this type are summarized in Table 2 (indocyanine green) and Table 3 (conjugated bilirubin) All cholephilic substances reduced the secretion of conjugated bilirubin and indocyanine green

In experiments designed to eliminate competition for uptake, the injection of one cholephilic substance (bunamiodyl, novobiocin or norethandrolone) was delayed for 20 min after the administration of the bilirubin glucuronide or indocyanine green in order to allow the liver to take up the latter without competition Each of the substances inhibited the excretion of indocyanine green and bilirubin glucuronide

Table 2 INHIBITION OF BILIARY SECRETION OF INDOCYANINE GREEN (0 13 μMOLE) IN THE RAT

Inhibitor	Dose (μmole)	Relative depression of secretion (%)
Novobiocin	1 3	47
	13	92
Novobiocin (Gunn rat)	13	72

Secretion by liver slices The accumulation of bilirubin glucuronide and *o*-aminophenol glucuronide in a medium in which liver slices were incubated was the basis of the standard procedures for demonstrating conjugation by slices The addition of novobiocin, bunamiodyl or norethandrolone reduced the yield of glucuronides in the medium In order to define the secretory process conjugated bilirubin was estimated in both slices and medium (Table 4). At certain concentrations, 0 01 m mole novobiocin, 1 m mole bunamiodyl, and 1 m mole norethandrolone it was noted that there was a reduction in the glucuronide passing into the medium during the 2 h of incubation although substantial amounts of glucuronide were formed, as demonstrated by the amount remaining in the slices Under these conditions it was concluded that the secretory process was inhibited more than the uptake of bilirubin, or its conjugation. Novobiocin reduces the total amount of bilirubin in the slice, indicating that it also inhibits the uptake of bilirubin

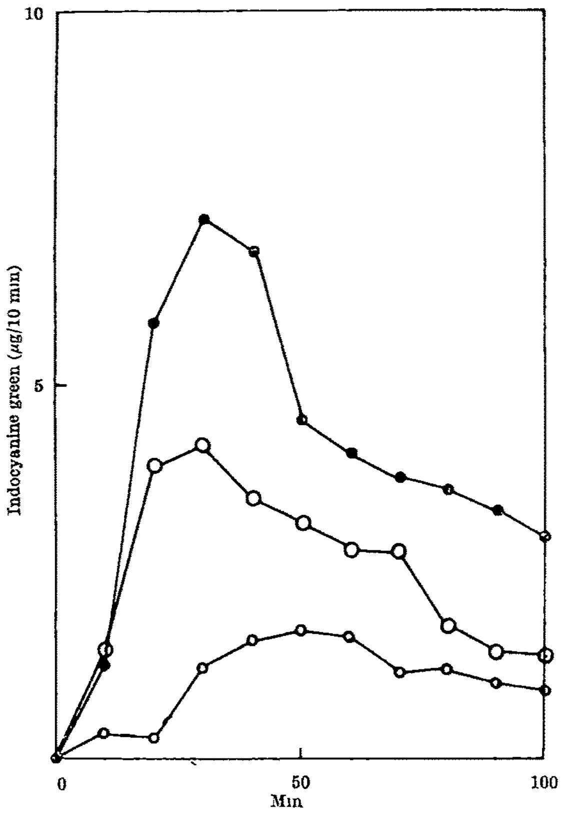

Fig 1 Effect of novobiocin on the concentration of indocyanine green in bile ●, control animal injected with 0 13 μmole indocyanine green Test animals injected with 0 13 μmole indocyanine green together with 1 3 μmoles (○) and 13 μmoles novobiocin (○)

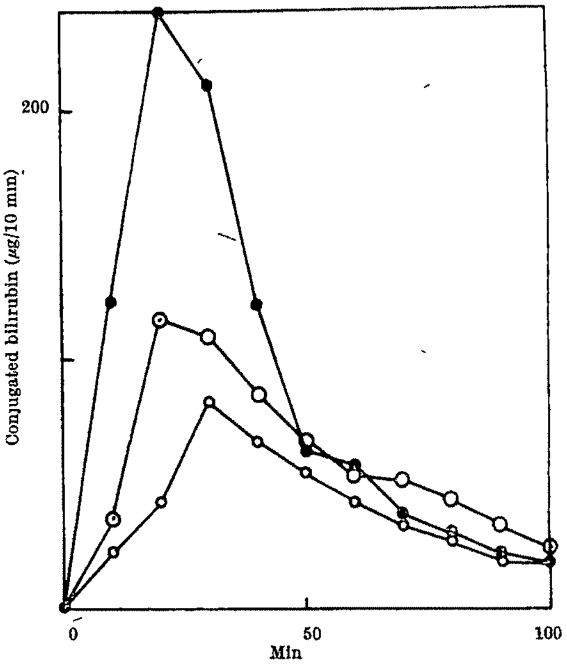

Fig 2 Effect of novobiocin on the concentration of conjugated bilirubin in bile ●, control animal injected with 0 6 μmole conjugated bilirubin Test animals injected with 0 6 μmole conjugated bilirubin together with 3 μmoles (○) and 30 μmoles (○) of novobiocin

In order to test the effect on the secretory mechanism which excluded the conjugating process, rat liver slices were incubated in the same medium used for examining conjugation of bilirubin, but bilirubin glucuronide was added in place of unconjugated bilirubin The effect of adding novobiocin, bunamiodyl and norethandrolone to such a system is given in Table 5 Each of the substances caused the slices to accumulate it

Table 5 INHIBITORS ON THE ACCUMULATION OF CONJUGATED BILIRUBIN IN LIVER SLICES

Most of the cholephilic substances examined have two properties in common they inhibit the *in vitro* formation of glucuronides in liver homogenates (Table 1), and the *in vivo* biliary excretion of both bilirubin glucuronide and indocyanine green, methicillin, chloral and norethandrolone appear to be inhibitors of glucuronide formation at higher concentrations than other cholephilic substances Fluorescein and phenol phthalein are excreted as glucuronides in bile, chloral is excreted as the glucuronide of trichlorethanol The mode of excretion of novobiocin, bunamiodyl, norethandrolone and methicillin is not known Billing[31] did not find an increase in glucuronic acid in the bile when novobiocin was administered to rats. All cholephils tested inhibited the biliary excretion of bilirubin glucuronide and indocyanine green *in vivo* Eight of eleven cholephilic substances inhibited glucuronide formation at a concentration of less than 1 m mole, including four cholephils which are not secreted as glucuronides

The *in vivo* investigations are open to the criticism that they may be affected by factors other than the biliary concentrating capacity Secretion into the bile could be retarded by a decreased hepatic circulation as a result of the administration of cholephilic substances, this seems improbable since in each experiment the control study was made following the injection of one cholephilic substance. Circulatory factors do not play a part in the slice experiments (Tables 4 and 5) in which the secretory phenomenon was demonstrated We conclude that circulatory factors are unlikely to be very important Secretion into the bile can also be retarded by reduced uptake of indocyanine green or bilirubin by the liver, due to direct competition Novobiocin reduces the secretion of bilirubin glucuronide from the liver slice, but it also reduces the total amount of bilirubin in the slice (Tables 4 and 5) These results suggest that novobiocin affects the uptake of bilirubin as well as the secretion of bilirubin glucuronide In the case of bunamiodyl and norethandrolone the experiments shown in Tables 4 and 5 indicate that secretion into the medium is reduced more than uptake into the liver slices This suggests that the secreting mechanism is more sensitive to bunamiodyl and norethandrolone than either the mechanisms of uptake or of glucuronic acid conjugation Novobiocin has an effect on the uptake of bilirubin and on the secretory mechanism In order to demonstrate that all three substances affect the secretory mechanism the injection of the inhibitory cholephil was delayed in the *in vivo* investigations until the liver had taken up a large part of the bilirubin glucuronide or indocyanine green, this did not prevent the inhibitory effect

There are three possibilities to explain why cholephilic substances inhibit glucuronide formation by homogenates and the secretion of cholephils into bile First, glucuronide formation may play a part in the concentrating mechanism It seems improbable that the formation of glucuronides of all cholephilic substances is essential for concentration in the bile Indocyanine green was chosen for detailed investigation, together with bilirubin glucuronide, because the former is excreted chemically unaltered, rose bengal and bromsulphthalein can also be excreted unchanged. Bromsulphthalein is excreted normally in patients with familial non-hæmolytic hyperbilirubinæmia lacking the ability to conjugating bilirubin, and in the parallel condition in the jaundiced Gunn rat[32] We have also shown (Table 2) that indocyanine green is excreted by the jaundiced Gunn rat These observations do not exclude participation of glucuronyl transferase in the concentrating mechanism It is probable that there is more than one enzyme Gunn rats are able to form N-glucuronides[33], they can form glucuronides of N-acetyl o-aminophenol and menthol as can patients with familial non-hæmolytic hyperbilirubinæmia, albeit at a reduced rate[32] These observations suggest that a number of glucuronyl transferase enzymes occur Glucuronyl transferases have a second substrate, uridine diphosphate glucuronic acid Inhibition by cholephils could equally well occur at this enzyme site, should this be true it would suggest that uridine diphosphate glucuronic acid was involved in some way in the concentrating mechanism of bile secretion

Secondly, cholephilic substances may have a chemical property which makes them inhibitors of glucuronyl transferase This is unlikely because of the wide variety of chemical types represented (Table 1) unless the same chemical property which makes these substances cholephilic confers the capacity to inhibit glucuronyl transferase This is another way of suggesting that there is a chemical similarity between glucuronyl transferase and some key participant in the concentrating mechanism.

The third possibility is that there is a common pathway in the two processes of conjugation and secretion of cholephilic substances Glucuronide formation requires the enzyme glucuronyl transferase and the specific donor substance uridine diphosphate glucuronic acid. In slice experiments uridine diphosphate glucuronic acid is constantly generated; in broken cell experiments we added an amount of uridine diphosphate glucuronic acid which was nearly optimal for the reaction However, one may not assume that under these conditions the only factor is the kinetics of the enzyme, for glucuronyl transferase is not in solution, but part of the microsomal fraction In the intact cell it is attached to, and possibly embedded in, the phospholipid-rich, endoplasmic membranes In microsomal preparations cholephils may retard the access of substrates, like bilirubin, to the enzyme by competition for passage through the phospholipoid membrane Equally, egress of the glucuronide formed could be inhibited Theoretically, the concentrating mechanism could share either of these as a common pathway It is unlikely that competition occurs at the point of access to the enzyme because high concentrations of unconjugated bilirubin in patients with familial non-hæmolytic hyperbilirubinæmia and in jaundiced Gunn rats do not inhibit the biliary excretion of bromsulphthalein and iodipamide In contrast indocyanine green and bilirubin glucuronide compete for excretion in the normal and in the jaundiced Gunn rat; this indicates that competition for the concentrating mechanism can only occur after the enzyme If the two processes are distinct, it must follow that bilirubin can only get to the secreting mechanism via the glucuronyl transferase pathway, and once conjugated it is prevented from escaping into the cell sap or medium by the inhibitors We postulate that the only exit is via the secreting mechanism, glucuronyl transferase inhibition is then produced by an accumulation of bilirubin glucuronide, this would explain the inhibitory effect of cholephils on conjugation by homogenates and microsomes It should be possible to demonstrate the accumulation of bilirubin glucuronide in inhibited microsomes, similar to the experiment of Table 5 with slices, but we have been unsuccessful in attempts to do this In view of the possible close relation between microsomes and the concentrating mechanism we examined the effect of cholephilic substances on two other microsomal enzymes, glucose-6-phosphatase and the hexobarbitone metabolizing enzyme Both were inhibited by some of these substances but less consistently than glucuronyl transferase and at relatively high concentrations

The evidence suggests that cholephilic substances act on a part of the secretory mechanism, but this is not necessarily the only site of action of these substances Some may affect the mechanism of uptake into the liver, the path of access to the enzyme or glucuronyl transferase directly Two cholephilic substances, bunamiodyl and novobiocin, produce an increased plasma concentration of unconjugated bilirubin in patients in certain circumstances In the case of novobiocin this could be due to a block in the uptake of bilirubin, inhibition of the conjugating enzyme, or it could be an effect on the secretory mechanism Bunamiodyl acts on the secretory mechanism We do not consider that the accumulation of bilirubin rather than bilirubin glucuronide excludes a block of the mechanism secreting cholephils Jaundice due to norethandrolone is associated with conjugated bilirubin in the plasma and it takes some days to develop It is probably not the immediate effect of enzyme inhibition, as suggested by Hsia, Dowben, Shaw and Grossman[34], but a more chronic and secondary effect on the concentrating mechanism limiting the movement of bilirubin glucuronide, and so allowing this to appear in the plasma

We thank the Medical Research Council and the British Empire Cancer Campaign for financial assistance, also Upjohn of England, Ltd , Beecham Research Laboratories, Ltd , G D Searle and Co , Ltd , and Benge and Co , Ltd , who gave generous amounts of novobiocin, methicillin, norethandrolone and bunamiodyl respectively

6-AMINONICOTINAMIDE AND THE RADIOSENSITIVITY OF HUMAN LIVER CELLS IN CULTURE

By DR D L DEWEY and CHRISTINE HAWES

British Empire Cancer Campaign Research Unit in Radiobiology, Mount Vernon Hospital, Northwood, Middlesex

6-AMINONICOTINAMIDE is a structural analogue of nicotinamide, and the physiological disturbances which it causes in the animal organism are thought to be due to its incorporation into co-enzymes with a consequent loss of their normal function Herter *et al* [1] have shown that daily doses of 6-aminonicotinamide are not toxic to patients until the cumulative dose exceeds about 5 mg/kg body-weight However, in animal experiments the tolerated dose has been increased nearly nine times by the simultaneous injection of nicotinamide[2] Combination therapy using 6-aminonicotinamide together with irradiation has already been claimed to increase tumour regression in mice[3]

With a possible clinical use in mind, Dr L G Picciotto suggested testing the effect of 6-aminonicotinamide on the radiosensitivity of human cells in culture For these experiments a strain of human fœtal liver cells was used and the effect of radiation on colony-forming ability was measured In order to obtain accurate control of temperature and oxygen tension and to ensure a uniform dose distribution the irradiations were carried out in a water-jacketed nylon vessel at 37° C and the cells were suspended in phosphate-buffered medium with or without 6-aminonicotinamide at a concentration of 2 mM The suspension was rotated by a strong jet of air impinging on the surface and was also stirred with a motor-driven nylon paddle Samples withdrawn just before and immediately after irradiation with 200-kV X-rays were diluted if necessary and added to heavily irradiated feeder layers in glass bottles containing bicarbonate medium Cultures which had been exposed to 2 mM 6-aminonicotinamide were then treated with nicotinamide at a final concentration of 20 mM in order to reverse the inhibitory effect of the analogue on cell growth Complete reversal by nicotinamide was possible within an hour of adding the 6-aminonicotinamide The cultures were incubated at 37° C for 10 days and the number of colonies containing more than 32 cells at this time was taken as a measure of the number of surviving cells in the sample added

The log surviving fraction plotted against X-ray dose could be represented by a line with an initial shoulder followed by a straight portion. In the absence of 6-aminonicotinamide the dose giving 37 per cent survival on the straight line part was 140 rads, slightly greater than the 120 rads previously reported for the same cells irradiated at 20° C (ref 4) The effect of adding 6-aminonicotinamide to a final concentration of 2 mM shortly before irradiation is shown in Fig 1 The immediate impression conveyed by the result displayed in Fig 1 is that 6-aminonicotinamide sensitizes cells to radiation damage, and preliminary reports have already been published to this effect[5,6] More recent work using abnormal telophase figures as the criterion of damage suggested that the results shown in Fig 1 might not be due to radiosensitization[7]

Ehrlich ascites tumour cells of the mouse were used in the initial work on chromosome abnormalities, which were examined in telophase of the first post-irradiation mitosis The effect of 6-aminonicotinamide on the radiosensitivity of these cells *in vivo* was tested by irradiating 5-day ascites tumours in the mouse peritoneal cavity in the presence or absence of the analogue Two groups of mice were injected intraperitoneally with 0 65 ml of an 80 mM solution of 6-aminonicotinamide 0 5 h before they received 300 rads total-body irradiation The

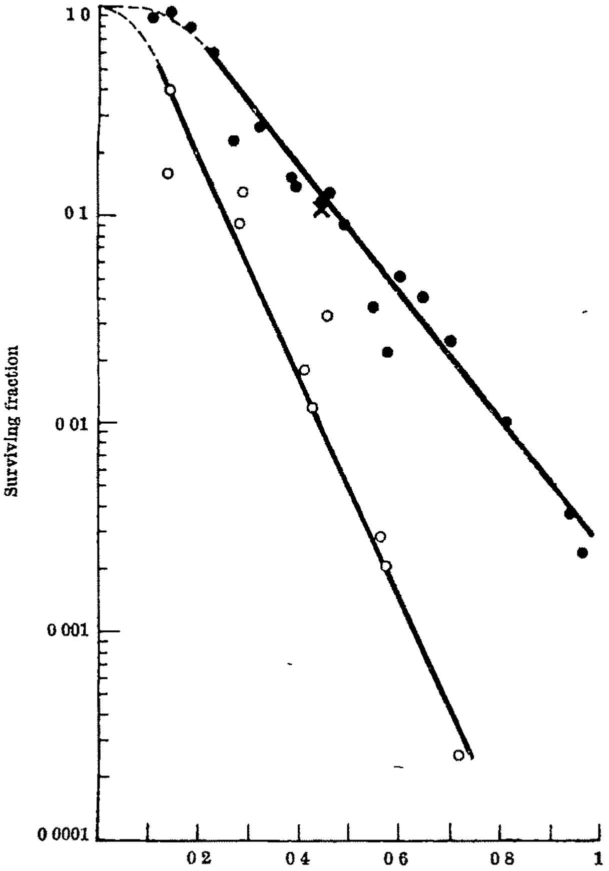

Fig 1 The colony-forming ability of human embryo liver cells in culture after exposure to 200-kV X-rays ●, Cells irradiated in suspension in a phosphate-buffered medium, ○, cells irradiated in medium containing 2 mM 6-aminonicotinamide, ×, 6-aminonicotinamide added to cells after irradiation

mice in one group were then injected with nicotinamide. Half an hour after irradiation the ascitic suspensions were transferred into unirradiated host mice and incubated for 15 h, at which time the proportion of abnormal telophase figures attained a maximum value The results given in Table 1 (experiment 1) show that 6-amino-nicotinamide had no effect on the observed amount of radiation-induced damage

In view of this negative result it was decided to repeat the chromosome damage experiment under controlled *in vitro* conditions Ascitic suspensions diluted with phosphate-buffered saline were brought into equilibrium with oxygen and irradiated in the 'Perspex' vessel described by Deschner and Gray[8] 6-Aminonicotinamide at a final concentration of 8 mM was added to the test sample 15 min before irradiation and chromosome damage was estimated as in the *in vivo* experiments The results of irradiating cells in the presence of 6-aminonicotinamide together with results of controls in which the analogue was absent or was added immediately after irradiation are given in Table 1 (exp 2) Again there was no evidence of any sensitization

The apparent lack of correlation between results obtained using colony-forming ability on one hand and chromosome abnormality on the other as criteria of damage required further investigation The possibility of explaining the discrepancy as a species difference was eliminated by repeating the chromosome investigations on the same human cell line which was used in the experiments measuring reproductive integrity The cells were grown on glass coverslips in small Petri dishes at 37° C for about 45 h before irradiation The entire experiment was carried out in a 'Perspex' gas-tight incubator designed to allow irradiation of the cultures through the closed lid All the Petri dishes were irradiated at the same time, half of them having received 6-aminonicotinamide at a concentration of 2 mM 26 min prior to irradiation Throughout this procedure, the incubator was gassed with air containing 6 per cent carbon dioxide. After the X-ray exposure, nicotinamide at a final concentration of 20 mM was added to the experimental cultures and the control cultures were incubated in 2 mM 6-amino-nicotinamide for an equivalent length of time before nicotinamide was added Previous experiments had shown that the percentage of abnormal telophase cells reached a maximum 23 h after irradiation At this time the coverslips were transferred to fixative and the cells were stained and examined As in the earlier experiments with the Ehrlich tumour the presence of 6-aminonicotinamide during irradiation had no effect on the radiosensitivity of the human cells as measured by chromosome damage (Table 1, exp. 4)

These results indicated a difference in the effect of 6-aminonicotinamide on radiosensitivity as measured by chromosome damage on one hand or reproductive death on the other, the possibility was investigated that this difference was due to a change in technique between the two types of experiment In the earlier experiments establishing the dose-response relations for the destruction of reproductive integrity (Fig 1), the cells were irradiated in suspension rather than in contact with the glass bottles to eliminate uncertainties in radiation dosimetry However, in the work on chromosome damage, the cells were growing on glass coverslips when they were exposed to 6-aminonicotinamide and radiation The survival investigations were therefore repeated on cells which were stuck to a surface at the time of treatment Cells growing in glass bottles were given the same dose of irradiation either in the presence or in the absence of 6-aminonicotinamide and the resulting colonies were counted in the normal way The results showed that 6-aminonicotinamide had no effect on radiosensitivity under these conditions

The essential difference between the earlier positive result shown in Fig. 1 and the later negative results is that in the former experiment 6-aminonicotinamide was added before the cells were allowed to attach to glass and the order was reversed in the later experiments The conclusion we drew was that 6-aminonicotinamide reduced the plating efficiency and this was later confirmed by an experiment designed to measure this effect directly

Table 1 CHROMOSOME DAMAGE INDUCED BY X-IRRADIATION IN THE PRESENCE OR ABSENCE OF 6-AMINONICOTINAMIDE (6 AN)

Exp	Material	Irradiation†	Abnormal telophases (per cent)		
			Control	6 AN before and during irradiation	6 AN after irradiation
1	Mouse ascites tumour cells	0 r	7 7 (2)	9 8 (2) 8 5 (1)*	
		300 r *in vivo*	76 3 (5)	76 8 (4) 74 7 (5)*	
2	Mouse ascites tumour cells	0 r	5 2 (3)	8 7 (4)	
		112 r *in vitro* gas phase oxygen	63 6 (4)	56 6 (4)	65 0 (2)
3	Human fœtal liver cells	0 r	7 2 (3)	8 6 (2)*	
4	Human fœtal liver cells	170 r. *in vitro* gas phase air		58 1 (6)*	59 5 (6)*

* Excess nicotinamide added within 1 h of adding 6 AN

† Dose measured in roentgens in air at the position of the irradiated sample

The figures in brackets refer to the number of observations made For each observation, a minimum of 200 telophase cells was scored from a single mouse or coverslip culture

In the earlier work, cells irradiated in suspension were afterwards diluted to give approximately the same number of viable cells per ml before plating As a result, 6-aminonicotinamide present in irradiated suspensions was diluted to a much greater extent after low doses than after high doses of radiation Thus the reduction of plating efficiency with increasing concentration of 6-aminonicotinamide gave an apparent survival curve of steeper slope than the control curve

The foregoing account has described the experiments in chronological order to illustrate how easily an experimental result can be misinterpreted In this case, it is interesting to note that the initial control in which 6-aminonicotinamide was added after irradiation (Fig 1) did not show the apparent sensitization, which may be accounted for by the fact that these cells were plated before the 6-aminonicotinamide was added

CHANGES IN THE ELECTROPHORETIC PROPERTIES OF RABBIT SPERMATOZOA DURING PASSAGE THROUGH THE EPIDIDYMIS

By J. M. BEDFORD
Department of Physiology, Royal Veterinary College, London, N W 1

WHEN washed free of seminal plasma or taken directly from the vas deferens or cauda epididymis, motile mammalian spermatozoa exhibit a marked tendency to agglutinate by the head region if suspended in homologous heated serum, or in isotonic media containing free electrolytes[1] During examination of spermatozoa collected from different regions of the rabbit epididymis it was noticed that in 0 145 M sodium chloride, spermatozoa from the caput region show little capacity for head–head autoagglutination As sperm move toward the cauda region, however, an increasing percentage exhibits the capacity for autoagglutination (unpublished observations) Mammalian spermatozoa are known to mature with respect to their fertilizing ability, during passage from the caput to the cauda epididymis[2,3], and thus it seemed possible that the progressive increase in the capacity for autoagglutination during this passage might reflect surface changes of importance in the epididymal stage of the sperm maturation process

The surface characteristics of cells, as reflected in the ζ potential, have been investigated in several studies by means of controlled electrokinetic measurements[4-7] On the assumption that differences in genotype might be reflected in the sperm phenotype, and specifically in the surface character of spermatozoa, this method has also been applied by several investigators in attempts to separate male and female determining spermatozoa[8] In an attempt to obtain evidence for the existence of some change in the character of the sperm surface during the period of epididymal maturation, the electrophoretic behaviour of spermatozoa from different regions of the epididymis has been examined therefore, using an apparatus similar to that described by Bangham *et al* [9]

Adult male rabbits were killed by dislocation of the neck, and spermatozoa were immediately taken from the caput, corpus and cauda regions of the epididymis (Fig 1) by incising and squeezing these tissues in a medium of 0 145 M sodium chloride The sperm suspensions were then adjusted to a concentration of approximately 2 million/ml and were cooled to 10° C, at this temperature many spermatozoa from the corpus and cauda regions still showed definite though sluggish swimming movement The sperm were then transferred to the microelectrophoresis apparatus, the bath of which was maintained at 4° C. At this latter temperature the great majority of spermatozoa soon became immotile, though if the temperature were allowed to rise, independent sperm movement was again resumed As in earlier investigations[8,10], the sperm were immobilized by cooling in order that any movement of the sperm might be interpreted solely in terms of the response of a charged particle in a d c electric field All recordings were made at 50 V with a current of 1 0 m amp, at 4° C Under these conditions the resultant electrophoretic component was great enough to produce a measurable response in the spermatozoa, while any rise in temperature and drift due to convection currents were delayed long enough for an adequate number of readings to be obtained from each sample Accurate measurements were made of the electrophoretic mobility of individual spermatozoa and of the time taken for complete re-orientation of oriented sperm after reversal of the direction of the electric field Estimates were made of the time for any sperm population to reach a maximum state of orientation, and of the mode of orientation, that is, the percentage of spermatozoa oriented tail first, head first, or pointing vertically with respect to the attractive electrode In Table 1 it can be seen that, with the possible exception of rabbit 2, the mean mobility of sperm populations from the respective regions of the epididymis was similar in all animals, but in each animal the mean mobility of spermatozoa from the caput region was clearly lower than that of spermatozoa from the corpus and cauda regions, respectively From Fig 2 it is apparent that although caput spermatozoa generally exhibited relatively lower mobilities, a few caput sperm showed similar mobility to those sperm obtained from the cauda region This latter observation is consistent with the presence of a small percentage of fertile sperm in the caput region of the rabbit epididymis[11]

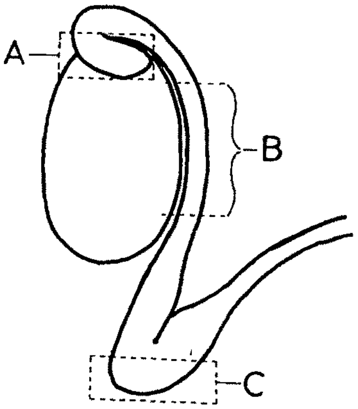

Fig 1 Diagram to show the regions of the caput (*A*), corpus (*B*), and cauda (*C*) epididymis, from which spermatozoa were recovered

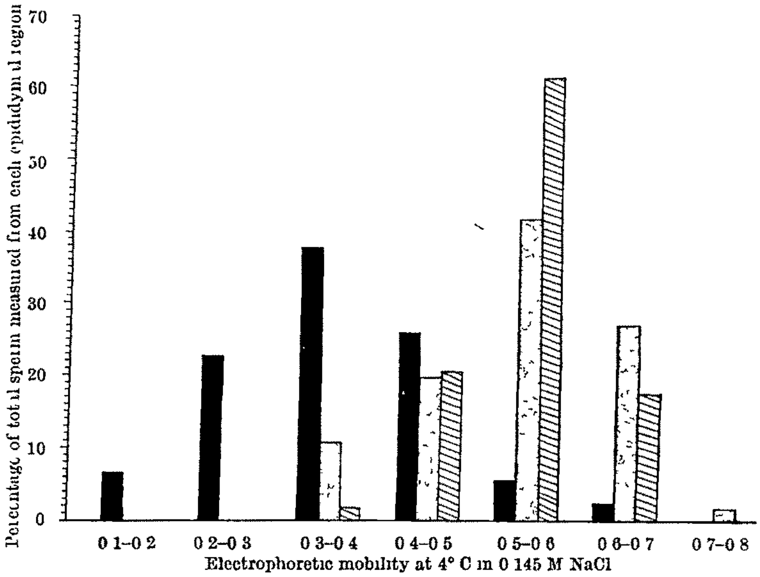

Fig 2 Histogram to show the distribution of electrophoretic mobilities (within a unit range) of spermatozoa from the different epididymal regions Black, caput spermatozoa, stippled, corpus spermatozoa, hatched, cauda spermatozoa

and with the observation that a few spermatozoa from the caput do show the capacity for autoagglutination

Unlike many other cell types which have been investigated by electrokinetic methods, the sperm cell is differentiated anatomically, and the surface membrane does not appear to exhibit uniform characteristics over the different anatomical regions[12] Thus, although the electrophoretic mobility may serve perhaps as one parameter for the measurement of sperm maturity, it seems that in order to obtain a true or complete indication of the state of the sperm surface, as reflected in the net surface charge, both the direction and speed of orientation must also be considered This is well demonstrated in a comparison of the measurements of sperm from the corpus and cauda regions Although the electrophoretic mobility was similar in sperm populations from both these regions (Table 1), the estimates of speed of initial orientation and the times for re-orientation following reversal of the electric field were markedly different in these sperm groups in each of the eight animals tested (Table 2) Under the influence of the particular field strength used, spermatozoa from the cauda region soon showed a definite orientation response, and after approximately 1–1 5 min the great majority of sperm were seen to be moving tail first toward the anode Spermatozoa taken from the corpus, on the other hand, orientated more slowly under identical conditions The majority of the spermatozoa from the corpus ultimately became orientated with the tail toward the anode, but some also remained vertical, and in several animals a small proportion of corpus spermatozoa became orientated with the head facing the anode Head anode orientation was seen more commonly, however, in spermatozoa from the caput region Compared with the behaviour of cauda spermatozoa, the tendency for orientation of caput spermatozoa was not immediately obvious, and in all caput samples the time allowed to elapse before the field could be deemed to have reached a state of maximum response to the electrophoretic component was relatively very much prolonged

Table 1 MEAN ELECTROPHORETIC MOBILITIES OF SPERMATOZOA TAKEN FROM CAPUT, CORPUS AND CAUDA EPIDIDYMIS, RESPECTIVELY EACH VALUE REPRESENTS THE MEAN OF NOT LESS THAN 12 SPERMATOZOA MOBILITY EXPRESSED AS μSEC^{-1} V^{-1} CM^{-1} AND MEASURED AT 4° C, IN 0 145 M SODIUM CHLORIDE

In rabbit No 8 no true orientation response could be elicited in sperm samples from either the corpus or from the caput regions, although a normal response was obtained from the cauda spermatozoa in this animal In the other animals, the time for re-orientation of caput and corpus spermatozoa (mean of at least three sperm taken at random from each group) was clearly longer in each case than the time required for the re-orientation of cauda spermatozoa

Difficulty was experienced in judging the orientation response of spermatozoa in which the tail had become bent at the locus of the cytoplasmic droplet In media of low ionic strength, that is, 6 per cent fructose, it appears that the droplet possesses similar electrophoretic properties to those of the sperm head In this medium, both the head and the droplet are obviously more strongly attracted to the anode than is the distal part of the tail Such inference of similar surface properties over the region of the droplet and the head is perhaps strengthened by the additional observation that, in media of high ionic strength, motile spermatozoa appear to adhere to the surface of glass slides either by the anterior and lateral regions of the sperm head, or by the cytoplasmic droplet In the latter case, the head and the tail oscillate freely while the droplet remains apparently adherent to the surface of the slide (unpublished observations)

Mammalian fertilization is a complex process which shows considerable dependence on the environment and on the specificity of the participating gametes Several differences in spermatozoa from the respective epididymal regions have been reported[13–16] Yet in the present state of our knowledge of the mammalian fertilization process, the increasing capacity for motility[17], which may be related conceivably to changes observed in midpiece mitochondria[18,19], and possibly, though less clearly, also changes in the proportions of the acrosome cap of rabbit spermatozoa[11], are the only differences so far recognized which may reasonably be correlated with the disparity in fertilizing ability of spermatozoa from different epididymal regions It has been suggested[20] that changes in the

permeability of the sperm surface occur during passage through the epididymis The present demonstration of the occurrence of marked changes in the electrophoretic behaviour of maturing epididymal spermatozoa, with the development of an increasing capacity for autoagglutination, make it seem fairly certain that changes do occur over the surface of spermatozoa during epididymal maturation It is not unreasonable to suppose that such differences in the sperm surface may be responsible in part for the evident inability of the majority of caput spermatozoa to penetrate the ovum

The nature of the change in the sperm surface during epididymal passage is open to further investigation The orientation of many caput sperm with the head pointing toward the anode indicates the existence of a relatively higher net surface charge over the head region in these spermatozoa The change in direction of orientation and the relatively higher mobility and speed of orientation of cauda spermatozoa under the same conditions reflect an absolute increase in the net negative surface charge over the tail, as the sperm pass through the proximal regions of the epididymis These latter findings are in accordance with the report by Nevo *et al* [10] that isolated tails of mature bull spermatozoa exhibit a higher net surface charge than do the isolated sperm heads The relatively slower tail–anode orientation response of most corpus spermatozoa suggests that the change is a gradual process, those spermatozoa remaining vertical in the electric field probably represent the stage or condition in which the net surface charge over the head approximately equals that of the tail region The question now remains as to whether or not an absolute reduction in the negative surface charge density of the head region occurs during epididymal passage of the sperm

The mechanism and significance of the 'stickiness' of mammalian spermatozoa are not understood, although it is clear that for autoagglutination of mammalian spermatozoa to occur, the surrounding medium must be of a certain ionic strength[1] It has been suggested that the adhesion of cells may depend to a certain degree on the principles advanced in the Verwey-Overbeek[21] theory for the stability of lyophobic colloids, in which the energy of interaction is presumed to depend in part on a repulsive force proportional to the net surface charge In the present context, it is noteworthy that spermatozoa fail to exhibit head–head agglutination in media in which head–anode orientation was shown in the microelectrophoresis cell, in this investigation, and in other unpublished studies using media of low ionic strength From this fact it seems possible to speculate that in media of low ionic strength the increased net surface charge over the head region in all epididymal spermatozoa may exert a repulsive force great enough to negate any inherent attractive forces in the sperm surface Although most caput spermatozoa fail to agglutinate also in media of high ionic strength, their weak head–anode orientation response in the electric field, in this type of medium, renders it probable that the failure to agglutinate may be due equally to the absence of attractive forces over the immature sperm surface

INDIVIDUAL AND SUB-GROUP ANTIGENIC SPECIFICITY OF BENCE-JONES PROTEIN

By Dr. STEFAN STEIN, Dr RALPH L. NACHMAN and
Dr RALPH L. ENGLE, jun
Department of Medicine, New York Hospital, Cornell Medical Center, New York City

BENCE-JONES proteins were classified immunologically into two antigenic groups, *A* and *B*, by Korngold in 1956[1] He identified antigenic groups among serum myeloma proteins as well[2] Mannik and Kunkel further classified all the immunoglobulins into two distinct antigenic groups[3] and demonstrated that the same antigenic determinants are involved in grouping immunoglobulins, serum myeloma proteins, and Bence-Jones proteins Thus, group 1 γ-globulins, Korngold group 1 myeloma proteins, and Korngold Type *B* Bence-Jones proteins share antigenic determinants and are all classified as group 1 Likewise, there is antigenic similarity among group 2 γ-globulins, Korngold group 2 myeloma proteins, and Korngold type *A* Bence-Jones proteins, these constitute group 2. This article will follow the nomenclature suggested by Mannik and Kunkel

Migita and Putnam demonstrated that the Bence-Jones proteins are related to the electrophoretically slow (*S*) fragment of a papain digest of the same antigenic type myeloma protein[4] In addition, they, as well as Mannik and Kunkel, showed that patients with group 1 serum myeloma proteins usually excrete group 1 Bence-Jones proteins, while those with group 2 serum myeloma proteins typically excrete group 2 Bence-Jones Edelman recently demonstrated the chemical and immunological correspondence between the Bence-Jones protein and light (*L*) chains cleaved from the myeloma protein of the same patient[5] The investigation reported here was undertaken to evaluate the antigenic nature of individual Bence-Jones proteins

Production of Group Specific Antisera to Bence-Jones Proteins Group specific Bence-Jones antibodies were produced in the following way Bence-Jones proteins were separated[6], typed[7], and injected into a series of New Zealand albino rabbits Each rabbit was injected with a total of 450 mg of a Bence-Jones protein from a

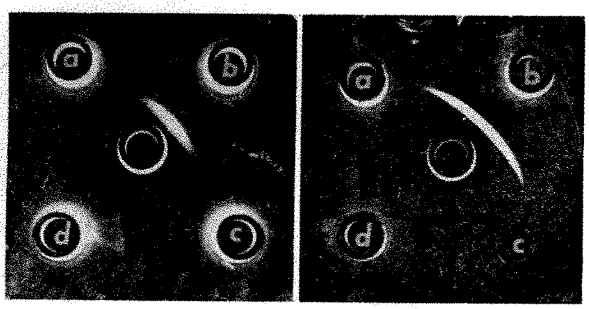

Fig. 1, left: Centre well, antibody against group 1 Bence-Jones (patient 40) absorbed with human serum. Fig. 3, left: Centre well, antibody against group 1 Bence-Jones (patient 40) absorbed with lyophilized normal human serum and group 1 Bence-Jones protein (patient 41). Peripheral wells: *a*, normal human serum; *b*, group 1 Bence-Jones (patient 40); *c*, group 1 Bence-Jones (patient 41); *d*, group 1 Bence-Jones (patient 42). Right: Centre well, antibody against group 2 Bence-Jones (patient 20) absorbed with normal human serum and group 2 Bence-Jones protein (patient 21). Peripheral wells: *a*, human serum; *b*, group 2 Bence-Jones (patient 20); *c*, group 2 Bence-Jones (patient 21); *d*, group 2 Bence-Jones (patient 23)

single patient using Freund's complete adjuvant, over a period of six months. Double immuno-diffusion agar-gel studies were performed[8] using 0·2 ml. antiserum in the centre well, and in peripheral wells, antigens consisting of 0·2 ml. of 0·1 per cent Bence-Jones proteins, 0·2 ml. pooled lyophilized human γ-globulin with concentrations varying from 1 to 160 mg/ml., or human serum diluted 1 : 10. The antisera were absorbed with normal human serum to remove antibody activity against non-specific contaminants present in the immunizing sample.

Antisera to group 1 Bence-Jones protein reacted with the group 1 protein, but not with group 2 proteins (Fig. 1, left). The typical double line of the group 1 reaction is seen. Identical specificity was demonstrated to group 2 Bence-Jones protein (Fig. 1, right). In no case did antisera to group 1 Bence-Jones proteins react with group 2 samples nor did group 2 antisera react with group 1 samples after absorption of the contaminants.

Demonstration of Antibody Potency following Absorption with γ-Globulin. Antisera were incubated at 37° C for 1·5 h with lyophilized pooled human γ-globulin (16 mg/ml. antiserum). The mixture was centrifuged at 13,000 r.p.m. for 30 min at 4° C. The clear supernate was used as absorbed antibody. These absorbed antisera reacted with the immunizing Bence-Jones protein as well as with other Bence-Jones proteins of the same antigenic group but from different patients. No reactivity was noted with γ-globulin (Fig. 2). Spur formation was observed in the group 2 system when the immunizing Bence-Jones protein was compared in adjacent wells with Bence-Jones proteins from different patients (Fig. 2, right). The spur formation suggests antigenic deficiency among the Bence-Jones proteins of the same group from different patients when compared with the immunizing Bence-Jones protein, and also suggests individual specificity of the immunizing Bence-Jones protein. No spur formation was demonstrable in the group 1 system.

Antisera to group 1 and 2 Bence-Jones proteins were individually absorbed with human serum (8 mg/ml.) as already described here. The supernate was further absorbed with 8 mg/ml. of Bence-Jones protein of the same group but from a different patient. In each case, the antibody retained activity against the immunizing Bence-Jones protein but lost potency to two other Bence-Jones proteins of the same group from different patients (Fig. 3). This reactivity was more pronounced in the group 2 system. These results further substantiate the evidence that Bence-Jones proteins are individually specific.

Relationship of Individual Bence-Jones Proteins of a Given Group to Each Other. As the γ-globulin absorption investigations indicate, Bence-Jones proteins of the same antigenic group react with the group specific Bence-Jones antibody despite γ-globulin absorption (16 mg/ml.) calculated to be greater than 10 times equivalence. These findings indicate that Bence-Jones proteins of the same antigenic group share a 'core' of determinants, which is common to the group. The fact that the 'common core' remains detectable after absorption of the antibody with γ-globulin suggests that it differs qualitatively or quantitatively from normal pooled human γ-globulin. According to present concepts, Bence-Jones proteins may be considered unincorporated components of the γ-globulin molecule and, therefore, may represent the product of asynchronous synthesis of a diseased plasma cell. Thus, any qualitative difference observed between the 'common core' shared by Bence-Jones proteins of a given group and normal pooled γ-globulins could be a function of: (1) preparative artefact; (2) unmasking of hidden antigenic sites; or (3) a true primary structural difference as might be expected of an abnormal protein. The proliferation of a clone of cells producing large amounts of a protein found in extremely small quantities in the normal spectrum of γ-globulins might explain a postulated quantitative difference. The data presented do not allow a clear determination of the foregoing possibilities.

IN VITRO CELL TRANSFORMATION WITH CHEMICAL CARCINOGENS

By YOHEVED BERWALD and Prof. LEO SACHS

Section of Genetics, Weizmann Institute of Science, Rehovoth, Israel

THE possibilities for the examination of chemical carcinogenesis could be considerably enhanced by demonstrating that the change of normal to tumour cells can be obtained *in vitro* with chemical carcinogens. Although there have been several attempts to induce this change *in vitro*[1], in earlier experiments the cells had been grown in tissue culture for long periods. It was still difficult to decide from these earlier experiments whether the altered cells found after treatment had been induced by the carcinogen that had been added[1], or whether there had been a selection in culture of altered cells that had arisen independently of the treatment.

One of the first steps in the examination of chemical carcinogenesis *in vitro* thus seemed to be to determine whether hereditary changes can be directly induced. We have paid particular attention to changes in organization resulting in a random arrangement of the cells, which will be referred to as a decrease in contact inhibition[2]. This criterion had been successfully used to establish *in vitro* transformation with polyoma virus (PV) (ref. 3), and with PV it was further found that *in vitro* transformed cells could progressively grow as tumours when inoculated into animals. The aim of the work recorded here was to determine: (*a*) whether cell transformation *in vitro* resulting in a hereditary decrease of contact inhibition can be obtained by treatment with chemical carcinogens; (*b*) whether these carcinogens can directly induce this transformation. Three chemical carcinogens, 3,4-benzpyrene (BP), 3-methylcholanthrene (MC), and ethyl carbamate (urethane), were tested with hamster and mouse cells. In addition to the treatment of short-term mass cultures, the effects of these carcinogens were tested on cells plated for cloning, to investigate the hereditary nature of any observed transformation, the frequency of transformed cells, and the possibility that the carcinogen merely selects transformed cells that occur spontaneously.

1- or 2-day-old secondary cultures from golden hamsters and *C57 B1/6* mouse whole embryos were used as a source of normal cells. Cultures were grown in 50-mm plastic Petri dishes (Falcon Co.) with Eagle's medium containing a four-fold concentration of amino-acids and vitamins plus 10 per cent calf serum, in a humidified incubator with a constant flow of 10 per cent carbon dioxide in air. Cells were cloned on X-irradiated rat feeder cells[4]. For the assay of transformed clones, the plates were fixed and stained with May-Grünwald-Giemsa after 7 days of incubation[4]. Plates were seeded at 1×10^6 cells for mass cultures and at 1×10^4 or 5×10^4 cells per plate for cloning.

The carcinogens BP and MC were used in the form of paraffin disks made of 'Millipore' filters[5] (0·45μ porosity and 150μ thickness) dipped into a solution of melted paraffin (m.p. 56° C) containing 5 per cent (w/w) of the carcinogen heated to 180° C. After the wax had solidified, the filters were cut into disks (0·6 cm diameter), with a paper punch, sterilized with 70 per cent ethanol, and stored in the dark. For treatment with BP or MC, one disk was added per Petri dish. Urethane was added directly to the culture medium. For the experiments with PV, mass cultures were infected with the small plaque polyoma mutant *SP2* (ref. 4) at a virus: cell ratio of 10 plaque forming units per cell (2 h adsorption), before the cells were plated for cloning.

The first experiments were carried out using BP and hamster cells, and it was repeatedly found that in addition to a toxic effect on a proportion of the cell population, there existed, among the survivors, cells that were fusiform in shape and exhibited a random pattern of growth. Colonies of such cells were found both after treatment of mass cultures with BP, and after treatment of cells which had been plated for cloning. No such colonies were found in untreated control cultures, or after treatment with disks containing only paraffin. It was seen from the cloning experiments that a hereditary cell transformation resulting in a decrease of contact inhibition had been obtained by treatment with BP *in vitro*. The transformed clones were identified by the random arrangement of cells with a fusiform tendency, and they could be distinguished from clones of cells transformed by PV, in that they did not pile up on one another as much as the PV transformed cells (Fig. 1). As in the case of PV transformation[4], there was still some degree of contact inhibition. Transformed cells could be inhibited from forming clones when grown together with normal cells in confluent cultures.

Representative results on cloning efficiency and percentage of transformed clones (that is, percentage of transformed/total number of clones), after various periods of BP treatment are given in Table 1. The results include experiments with BP treatment before cloning, after cloning, or both before and after cloning. All the experiments in Exp. 4 were carried out on one batch of cells, and those in Exp. 1 on another batch of cells. As expected, there was a considerable decrease in cloning efficiency of the BP-treated cultures due to the toxic effect of the carcinogen.

Table 1. PERCENTAGE OF *in vitro* TRANSFORMED HAMSTER EMBRYO CLONES AFTER TREATMENT WITH BENZPYRENE AND/OR POLYOMA VIRUS

Exp. No.	Type of treatment*	Time of BP treatment†	Total No. clones‡	Total No. BP transformed clones	Total No. PV transformed clones	Per cent cloning efficiency	Per cent BP transformed clones	Per cent PV transformed clones
1*A*	Paraffin	—	872	0	0	0·2	0	0
1*B*	BP	9 days b.c.	310	55	0	0·08	17·8	0
4*A*	None	—	615	0	0	1·5	0	0
4*B*	BP	2 days b.c.	478	25	0	0·6	5·2	0
4*C*	BP+PV	2 days b.c.	336	28	4	0·4	8·3	1·2
4*D*	BP	2 days b.c. +0 a.c.	692	57	0	0·2	8·2	0
4*E*	BP+PV	2 days b.c. +0 a.c.	322	52	1	0·1	16·1	0·3
4*F*	PV	—	~2,400	0	31	3·0	0	1·3
4*G*	BP	0 a.c.	231	38	0	0·6	16·5	0
4*H*	BP+PV	0 a.c.	582	98	0	0·7	16·8	0
4*I*	BP+PV	1 day a.c.	678	178	1	0·8	26·3	0·2
4*J*	BP+PV	3 days a.c.	618	127	6	0·8	20·6	1·0

* BP = benzpyrene; PV = polyoma virus; PV always inoculated and adsorbed for 2 h before cloning.

† b.c. = before cloning; a.c. = after cloning; 0 a.c. = BP added at time of cloning. Where b.c. only, no BP added after cloning. Where a.c. disks with BP present for 7 days if added at 0 a.c., for 6 days if added at 1 day a.c., and for 4 days if added at 3 days a.c. All plates were fixed and stained at 7 days after cloning.

‡ Plates seeded with 5×10^4 cells in Exps. 1*A*, 1*B*, 4*D* and 4*E*, and with 1×10^4 cells in all other experiments. A total of 4 plates seeded in Exps. 4*A* and 4*G*; and 8 plates in all other experiments.

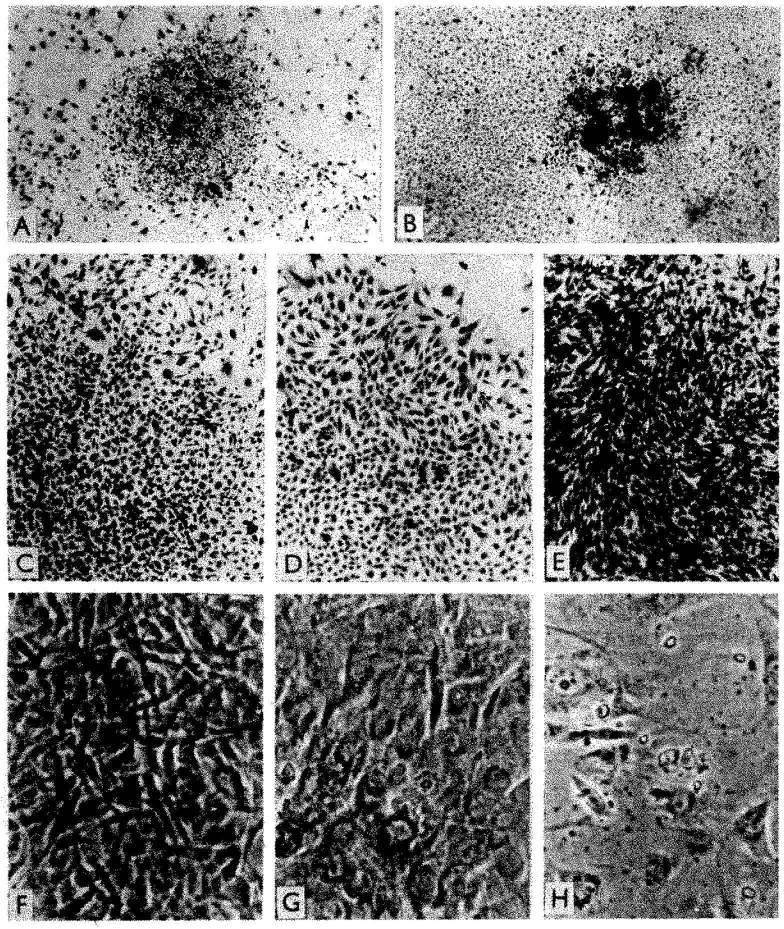

Fig. 1. All are photographs of cells derived from hamster embryos. *A–F* are clones and *G* and *H* are uncloned cultures. *A* = BP transformed (×*c.* 5·7). *B* = PV transformed (centre) and normal (×*c.* 5·7). *C* = BP transformed (×*c.* 18). *D* = normal (×*c.* 18). *E* = PV transformed (×*c.* 18). *F* = BP transformed (×*c.* 117). *G* = Normal (×*c.* 117). *H* = Same as *G* after 16 days of BP treatment to show toxic effects of carcinogen (×*c.* 117). *A–E* = fixed and stained; *F–H* = living cultures, phase contrast

In Exp. 1, mass cultures were treated with BP for 9 days and the cells then cloned. The results show that there were 17·8 per cent transformed clones in the experimental, and no transformed clones in cultures that had been pre-treated for the same period with disks containing only paraffin. A reduction of the period of treatment to 2 days before cloning (Exp. 4*B* and 4*C*) still gave, in two experiments, 5·2 and 8·3 per cent BP transformed clones in comparison to 1·3 per cent PV transformed clones. This percentage for PV transformation is comparable with that obtained in previous experiments with this PV mutant on hamster embryo cells grown under similar conditions[4]. The percentage of BP transformed clones in Exp. 4, with various times of treatment, ranged from 5·2 to 26·3 per cent.

It appeared unlikely, from the results of the 2-day treatment with BP before cloning, that the transformation was merely due to a selection by the carcinogen of transformed cells that had arisen spontaneously independently of the carcinogenic treatment. But in order further to establish this point, experiments were carried out on adding the carcinogen to cells that had been plated for cloning. The data show (Exps. 4*G*–4*J*) that when BP was added either at the time that the cells were plated for cloning, or even at 1 or 3 days after cell plating, there were 16·5–26·6 per cent BP transformed clones in the experimental cultures, and no such transformed clones in the untreated or PV infected cultures. Regarding the experiment where BP was added at three days after cloning, further cloning experiments are required to determine whether the transformed clones, obtained by adding carcinogen after cell divisions had presumably occurred in the clones, consist of a mixture of transformed and normal cells.

These results thus indicate that BP can induce *in vitro* cell transformation, and that this transformation, as in the case of PV induced transformation[4], was induced as a direct result of the action of the carcinogen, and not merely by the selection of spontaneously occurring transformed cells. Similar results have also been obtained after MC treatment of hamster embryo cells, and after BP and MC treatment of mouse embryo cells. The *in vivo* behaviour of the cells transformed by BP and MC *in vitro* is now being tested by cell inoculation into animals.

In contrast to the results with BP and MC, no transformed clones were found in a total of about 2,400[*] hamster embryo clones and 960 mouse embryo clones examined after treatment with urethane at 10 mg/ml. for 3 days before cloning. Urethane can produce different types of tumours *in vivo*, but it seems predominantly to produce tunours of the lung[6]. Further investigations should be able to establish whether these negative results with urethane are due to the absence of appropriate target cells in sufficient number in the embryo cultures used in the present experiments, or whether the absence of cell transformation *in vitro* may be related to the possibility that the carcinogenic effects *in vivo* are due not to urethane itself, but to some metabolic derivative that is produced in the animal but not in tissue culture. It should be noted that, although BP or MC applied as disks did not produce a toxic effect on cultures of two tumour-producing PV *in vitro* transformed cell lines (one from hamsters and one from *C57 Bl*/6 mice), whereas disks containing the same concentration of BP or MC produce a clear toxic effect on cultures of normal embryo cells, no such differential toxicity was found when the same cell lines were compared with normal embryo cells at urethane concentrations of 0·1, 1, 10 and 30 mg/ml.

Regarding the resistance to the toxic effects of carcinogenic hydrocarbons that has been observed with various tumours[5,7], treatment with BP at different times after PV infection (for example, Exps. 4*E*–4*J*) should enable one to establish exactly how long after virus infection PV transformed cells acquire this resistance.

A test on resistance to MC and BP and malignancy *in vivo* was also made with two cell populations of the long-term hamster tissue culture line *BHK*[8]. An uncloned population of *BHK* 21 gave, after 7 days' treatment of mass cultures with disks of MC or BP, 92 and 78 per cent, respectively, of the total cell count of paraffin-treated controls. However, clone 13, which was derived from an earlier passage of *BHK* 21 and showed a different growth pattern *in vitro*, gave after the same treatment 28 and 16 per cent, respectively, of the total cell count of the control cultures, and thus appeared to be as susceptible as normal hamster cells. One month after subcutaneous inoculation into 2-month-old hamsters, the uncloned *BHK* 21 inoculated at 2×10^4 cells per hamster had produced progressively growing tumours in 5/5 animals, whereas clone 13 had not produced tumours in 5 animals inoculated with 2×10^5 cells. The more resistant population of *BHK* was thus also more malignant *in vivo*. The mechanism of this resistance to carcinogenic hydrocarbons in the tumour cells tested is so far unknown. One possibility is that in resistant cells there may be a decreased penetration by the carcinogen owing to changes in the cell surface.

It can be seen from Table 1 that there was a survival of apparently normal-looking clones even in cultures treated with BP both before and after cloning. Further experiments including re-cloning are thus being carried out, to determine whether these apparently normal-looking clones have a hereditary resistance to the toxic action of BP or MC without a decrease in contact inhibition, and whether cells transformed by BP or MC are invariably resistant to the toxic action of these carcinogens.

The foregoing results seem to indicate the feasibility of studying cell transformation by chemical carcinogens *in vitro*, and a similar approach may prove useful to examine the *in vitro* effects of radiation. If the results of cell inoculations into animals will show that the cells transformed *in vitro* with chemical carcinogens can grow progressively as tumours *in vivo*, the present *in vitro* system may also prove useful as an additional test for carcinogens, and for determining whether the carcinogenic action of a compound *in vivo* is due directly to the compound itself or to some metabolic derivative produced in the animal.

TEICHOIC ACID AND THE GROUP ANTIGEN OF LACTIC STREPTOCOCCI (GROUP *N*)

By DR. S. D. ELLIOTT

The Rockefeller Institute, New York, and Department of Animal Pathology, University of Cambridge

THE immunological activity of bacterial glycerophosphate polymers (teichoic acids) was first described by McCarty[1], who extracted these substances from a variety of micro-organisms and found them reactive with serum containing antibodies to the polyglycerophosphate of group *A* streptococci. Recently, serologically reactive teichoic acids of taxonomic interest have been isolated from several bacterial species[2,3], and it is the purpose of the present communication to report an example from the lactic streptococci (group *N*) in which a galactosyl glycerophosphate polymer appears to be the group antigen.

Sharpe[4] found serologically identical type-specific antigens in certain strains of enterococci and lactic streptococci. I have confirmed this observation and furthermore have found that the type-specific carbohydrate antigens of enterococci are located in the bacterial cell-walls[5]. The group-specific antigen of the enterococci (group *D*), on the other hand, is an 'intracellular' glucosyl glycerophosphate polymer[2], and it seemed possible that a chemically similar but serologically distinct intracellular substance might be the group antigen for the lactic streptococci (group *N*). Accordingly, intracellular teichoic acid was extracted from two different strains of group *N* streptococci and subjected to chemical and serological analysis.

The group *N* streptococci selected for investigation were strains 6681 and *B*209. The former is catalogued under this name in the National Type Culture Collection but is sometimes referred to as the 'Orla Jensen' strain. Strain *B*209 came from the collection of Dr. R. C. Lancefield, who received it under the designation *LE*1 from Dr. J. M. Sherman.

Precipitin tests revealed in dialysate broth culture filtrates of strain 6681 a small amount of group *N* antigen; it was absent from culture filtrates of strain *B*209. This extracellular group antigen was precipitated from the culture filtrates by the addition of ammonium sulphate to 0·8 saturation and amounted to about one-tenth the yield later obtained by disrupting the cocci. The intracellular group antigen was extracted from both strains and partially purified by the procedures already described for the isolation of group *D* antigen from enterococci[5]. Washed cocci were disrupted by shaking with glass beads (Ballotini No. 13) in a mickle disintegrator and the cell contents separated from the cell-walls by centrifugation for 2 h at 40,000*g*. The cell contents fraction reacted strongly with group *N* antisera of heterologous type and continued to do so after digestion with nucleases and proteinases followed by prolonged dialysis against distilled water. The group *N* antigen was then precipitated from the digest by adding 1 volume of ethanol. After washing in ethanol and ether, the dried precipitate contained in addition to the group antigen approximately 30 per cent of nucleic acid. Most of the latter was removed by dissolving the dried material in 1 per cent calcium chloride and adding one-fifth volume of ethanol[6]. The nucleic acid was precipitated by this procedure while the group antigen remained in solution from which it, in turn, was precipitated by the addition of 1 volume of ethanol. This precipitate was washed in ethanol and ether and the dried material used for chemical analysis.

Samples of 5–10 mg were examined by paper chromatography after hydrolysis in 4 N hydrochloric acid for 6 h at 100° C. The chromatographic procedures and the quantitative methods later used for the estimation of hexoses and phosphorus were the same as had been utilized in the analysis of group *D* antigen[2,5].

When examined by paper chromatography acid hydrolysates of group *N* antigen preparations from both strains were found to contain glycerol phosphate, galactose phosphate and galactose. In addition, all preparations were contaminated with nucleic acid varying in amount from 3 to 30 per cent as estimated by absorption at 260 mμ. The most highly purified material came from strain 6681 and contained, in addition to glycerol, 10 per cent of galactose, 3·53 per cent of phosphorus and 3 per cent of nucleic acid. It seemed possible that in the group antigen galactose was present only in the phosphorylated form and that part of this became degraded during the acid hydrolysis preceding chromatography. In the quantitative determination of galactose[7], therefore, the group antigen preparations were compared with standard solutions of galactose-6-phosphate (barium salt) since this showed greater absorbancy at 600 mμ than did equivalent concentrations of *d*-galactose. The proportions of galactose and phosphorus in the best preparation, 10 per cent and 3·5 per cent respectively, are equivalent to a molecular ratio of 6 . 11·4 Assuming that the group N antigen is indeed a glycerophosphate compound, this ratio could be accounted for by a polymer the units of which each contained one galactose phosphate and one glycerol phosphate sub-unit, adjacent units being linked through the glycerol phosphate groups

Further evidence for the participation of galactose phosphate in the structure of the group N antigen came from the results of quantitative precipitin inhibition tests These showed that when galactose-6-phosphate and purified group N antigen from strain 6681 were present in a ratio of 500 1 there was approximately 25 per cent inhibition of precipitation by group N antiserum. No inhibition could be detected when either *d*-galactose or dextrose was substituted for galactose phosphate Both galactose-6-phosphate and galactose-1-phosphate had inhibitory activity, but the latter was not tested on a quantitative basis

Table 1. PRECIPITIN REACTIONS OF STREPTOCOCCAL TEICHOIC ACIDS

Streptococcal teichoic acid from	Rabbit antiserum to streptococci of stated group		
	Group A	Group D	Group N
Group A (1 mg/ml)	++	—	—
Group D (1 mg/ml)	+	++	—
Group N (0 1 mg/ml)	+	—	++

The results of precipitation reactions between intracellular teichoic acids from streptococci of groups A, D and N and their corresponding antisera are shown in Table 1 It will be seen that whereas the group A serum, containing antibodies to the unsubstituted glycerophosphate polymer, precipitates with all three teichoic acids, the group D and group N sera react only with the homologous antigens There are two obvious reasons for the cross-reaction between group N antigen preparations and the antiserum to group A polyglycerophosphate First, it may be due to the presence of unsubstituted polyglycerophosphate in the group N preparations In support of this explanation, intracellular material from strain B209 was found to contain a mixture of glycerophosphate and galactosyl glycerophosphate polymers from which the former could, in part at least, be separated by virtue of its greater solubility in ethanol or trichloroacetic acid A similar mixture may also have been present in the group N preparations from strain 6681, although here a separation of the two components was not achieved Evidence suggestive of such a mixture, however, came from gel-diffusion experiments in which group N preparations from strain 6681 when tested against group A polyglycerophosphate antiserum formed two precipitin lines one of which was continuous with the line formed by group A polyglycerophosphate Secondly, the serological cross-reaction may be due to the glycerophosphate 'backbone' common to the structure of both the unsubstituted and the galactosyl substituted polymer In support of this explanation is the result of an absorption experiment in which purified group N antigen from strain 6681 (0 1 mg) was mixed with serum containing antibodies to group A polyglycerophosphate (1 ml) The group N antigen was completely precipitated from solution by the polyglycerophosphate antibodies, and at the end of the experiment the absorbed serum no longer reacted with the homologous glycerophosphate polymer

In summary, it appears that the group antigen of the lactic streptococci (group N) contains galactosyl glycerophosphate probably in a polymerized form Galactose phosphate constitutes part at least of the immunologically determinant group Some streptococci of group N contain a mixture of galactosyl and unsubstituted glycerophosphate polymers

I thank Dr R C Lancefield for group N antisera and Dr E C Gotschlich for the phosphorus determinations The work was supported in part by U S. Public Health Service grant *HE* 04379

EVIDENCE FOR NON-ALLELISM BETWEEN GENES AFFECTING HUMAN SERUM CHOLINESTERASE

By PROF H. HARRIS, E. B. ROBSON and A. M. GLEN-BOTT
Medical Research Council Human Biochemical Genetics Research Unit and
Department of Biochemistry, King's College, London
AND
J. A. THORNTON
Department of Anæsthetics, University of Sheffield

AN examination of human serum cholinesterase by starch-gel electrophoresis, using sera from many different individuals, revealed that several components with the characteristics of that enzyme were regularly present, though one of these components, referred to as C_4, was very much more prominent than the others[1,2]. Furthermore, in some sera an extra component, C_5, was found This appeared to be an individual characteristic and to be genetically determined The C_5+ phenotype has now been observed in about 10 per cent of a random sample of British people, and family examinations indicate that most individuals of this phenotype are probably heterozygous for a gene which determines the presence of the component Another interesting feature is that C_5+ individuals have been found to have, on the average, slightly higher levels of serum cholinesterase activity than C_5- individuals[2], a finding which suggests that the C_5 component may have no detectable counterpart in the C_5- phenotype

It has also been shown that a gene which determines the occurrence of an atypical form of serum cholinesterase with unusual inhibition properties occurs with a frequency of about 0 02 in British and other European populations[3] This gene will be referred to as E_1^a and its common allele as E_1^u. The three genotypes $E_1^uE_1^u$, $E_1^uE_1^a$ and $E_1^aE_1^a$ are generally distinguished by determining what has been called the dibucaine number (DN)[4] This is the percentage inhibition of serum cholinesterase activity produced by the inhibitor dibucaine under certain standard conditions $E_1^uE_1^u$, $E_1^uE_1^a$ and $E_1^aE_1^a$ individuals have DNs of around 80 ± 2, 62 ± 4, and 20 ± 3 respectively, and are said to have the 'usual' (U), 'intermediate' (I) and 'atypical' (A) phenotypes as defined by dibucaine number determination[5].

The question arises as to whether the gene which determines the occurrence of C_5 is allelic or non-allelic to the genes E_1^u and E_1^a We have obtained information about this from the examination of two kindreds in

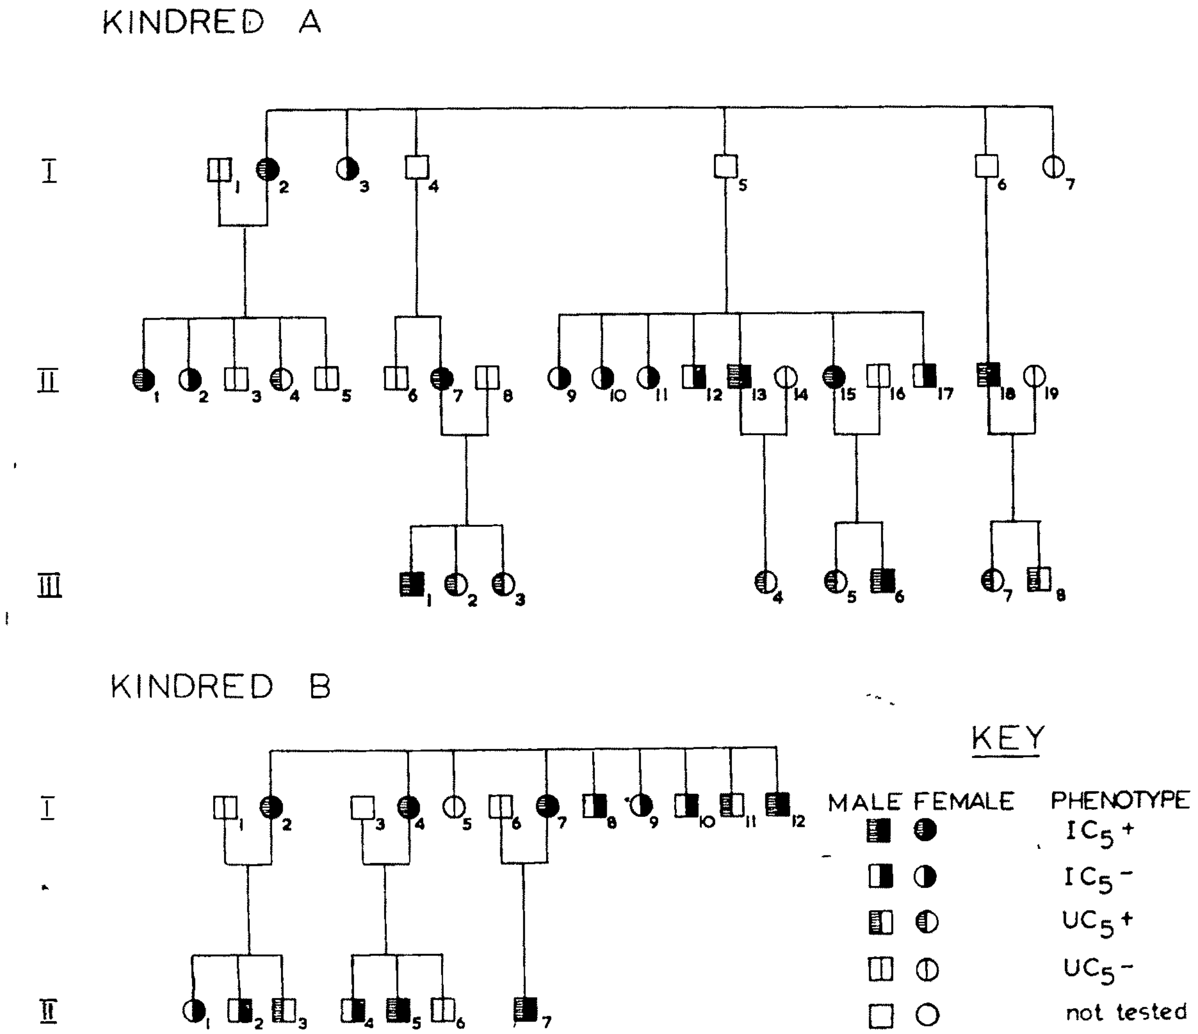

Fig 1 Pedigrees of two kindreds in which the four phenotypes UC_5-, UC_5+, IC_5- and IC_5+ are found

which all these genes are segregating Individuals of four different phenotypes could be identified by a combination of the results obtained from starch-gel electrophoresis with those obtained from DN determination using whole serum The four phenotypes will be referred to here as UC_5-, UC_5+, IC_5- and IC_5+ The critical families in testing for allelism or non-allelism are those where one parent is heterozygous for the gene E_1^a and also for the gene determining C_5 (phenotype IC_5+), and the other parent is homozygous for the usual allele or alleles (phenotype UC_5-) The relevant parts of the kindreds are shown in Fig 1 There are seven matings of the critical type where both parents could be examined, and among the seventeen children of these matings four phenotypes were observed with the following frequencies UC_5 − 2, UC_5 + 8, IC_5 − 3, IC_5 + 4 There was also one mating of a woman of the IC_5+ phenotype where the husband could not be tested but had a high probability of being of the UC_5- phenotype In this case the three children were respectively UC_5-, IC_5- and IC_5+ If the genes are non-allelic four different genotypes would be expected among the children of such matings and the four corresponding phenotypes were in fact observed If the genes are allelic only two genotypes (corresponding to the phenotypes UC_5+ and IC_5-) would be expected However, the interpretation is slightly complicated because it has been found that in occasional individuals, who, from their family relationships, would be expected to be carrying the gene determining the presence of C_5, the component cannot be demonstrated Such 'overlaps' might simulate non-allelism in the foregoing test, even if the genes were allelic However, if the genes were indeed allelic, it would be necessary, in order to explain the results, to postulate an unreasonably high rate of non-manifestation. Thus, to account for the IC_5+ individuals among the children in these families, it would be necessary, if the genes were allelic, to suppose that at least 4 out of these 7 UC_5- tested parents were in fact heterozygous for the gene determining C_5 They were all unrelated, and it has been estimated from other investigations that less than one in fifty of randomly selected individuals with the phenotype UC_1- in the English population are non-manifesting heterozygotes for the gene determining C_5 Thus, it is very likely that the genes are non-allelic

If the occurrence of component C_5 depends on a gene at a locus different from the locus of the genes E_1^u and E_1^a, it is of some interest to know whether E_1^u and E_1^a affect the inhibition characteristics of C_5 in the same way as they affect the inhibition characteristics of component C_4, which constitutes the major proportion of the serum cholinesterase in both C_5- and C_5+ individuals We have examined these points by comparing the inhibition characteristics of components C_4 and C_5 after their separation in starch gel

Horizontal unidimensional starch-gel electrophoresis was carried out using a *tris*/citrate buffer system at *p*H 5 0 (gel buffer 0 016 M succinic acid, 0 0184 M *tris* bridge buffer 1 6 M sodium hydroxide, 0 41 M citric acid) The zones of serum cholinesterase activity were detected, as previously described[2], using α-naphthyl acetate as substrate In each experiment the same set of serum

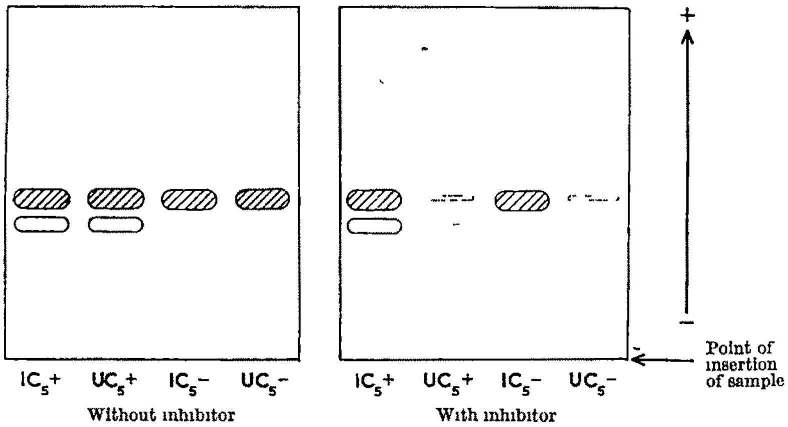

Fig 2 Diagram showing the effect of the inhibitor *RO* 2–0683 (10^{-7} M) on serum cholinesterase components C_4 and C_5 in individuals of the U and I phenotypes The C_4 and C_5 components were separated by starch-gel electrophoresis at *p*H 5 The sera in the gel without the inhibitor were diluted 1 in 4 with buffer, while the sera in the gel containing inhibitor were undiluted

samples was run on two separate gels in the presence and in the absence of inhibitor The inhibitor used was *RO* 2–0683 (Roche), which has been shown to give a somewhat greater discrimination between the 'usual' and 'intermediate' phenotypes than dibucaine[6] It was usually added to the appropriate gel and bridge buffers to a concentration of 10^{-7} M Sera of the four phenotypes UC_5-, IC_5-, UC_5+ and IC_5+ were used The degree of inhibition was established approximately by comparing undiluted serum on the gel with inhibitor with serial dilutions of serum on the gel without inhibitor

The results of a typical experiment are shown diagrammatically in Fig 2 Sera of types UC_5- and IC_5- give only a single zone of activity in the gel without inhibitor This is mainly C_4 The minor components C_1, C_2, C_3, etc , are not detected under these conditions In the gel with inhibitor (10^{-7} M) the IC_5- serum shows a single zone with about 25 per cent of the original activity, whereas the UC_5- zone is almost completely inhibited (less than 2 per cent of the original activity) Thus the 'usual' and 'intermediate' types of reaction to inhibitor can be readily distinguished visually Sera of types UC_5+ and IC_5+ show two zones of activity in the gel without inhibitor, the regularly present zone C_4 and the additional zone C_5 In the gel with inhibitor both zones in the UC_5+ serum are almost completely inhibited, and both zones in the IC_5+ serum are partially inhibited to the same degree (about 25 per cent of the original activity) In each case the degree of inhibition of the C_5 zone is essentially the same as that of the C_4 zone The same effect has also been observed with other concentrations of inhibitor Thus, the gene E_1^a affects the inhibition characteristics of the component C_5 in the same way that it affects the main serum cholinesterase component C_4 One may note that since there is evidence that in the sera of individuals who show the 'intermediate' DN phenotype there are actually present both the 'usual' and 'atypical' forms of the enzyme[7,8], it is likely that in IC_5+ individuals the C_5 zone may represent two distinct components, one having 'usual' type and the other having 'atypical' type DN characteristics

Although the molecular basis of the variations is unknown, one may conclude from these observations that the occurrence and the properties of the C_5 component are determined by genes at at least two loci

We thank Dr G Owen of the Department of Biochemistry, City General Hospital, Sheffield, for his help

OXYGEN DIFFUSION RATES AND NEMATODE MOVEMENT IN CELLULOSE SPONGES

By S. D VAN GUNDY and Dr L H STOLZY
Department of Nematology and Department of Soils and Plant Nutrition,
University of California, Riverside

THE influence of low oxygen diffusion rates in soils on nematode activity has been demonstrated by us[1] Efforts to examine different phases of nematode activity *in vitro*, however, have been hindered because no medium was available which provided an oxygen diffusion rate comparable to those recorded in soil studies A pure cellulose sponge ('O-cello', manufactured by General Mills) was selected as a synthetic medium because it was relatively inert, had structure, was made of pores of different sizes, and provided continuous and connecting surfaces. This is a report on the moisture and oxygen diffusion rate determinations of the sponge and on its use for investigating one phase of nematode activity, movement

Determinations of moisture and oxygen diffusion rate were made in 7 cm × 9 cm × 2 cm sponge blocks The sponges were washed in acetone and in water, dried at 60° C, and weighed They were saturated with tap water and placed on a double-walled ceramic suction plate Ten platinum microelectrodes[2] were placed in the sponge Water content and oxygen diffusion rate in relation to suction were determined from 0–90 millibars (mb) at a constant temperature of 25° C (Fig 1) The oxygen diffusion rate increased as the larger pores of the sponge

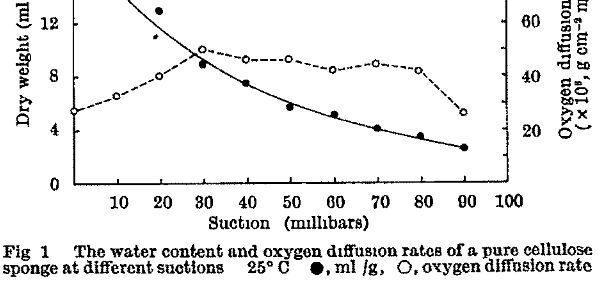

Fig 1 The water content and oxygen diffusion rates of a pure cellulose sponge at different suctions 25° C ●, ml /g, O, oxygen diffusion rate

drained. A suction of 30 mb appeared to drain a sufficient number of pores to allow maximum oxygen diffusion. The oxygen diffusion rate then remained nearly constant to 80 mb where the water films became too thin to wet the electrodes.

A method and apparatus for varying the oxygen concentration above the soil surface have been described[3]. The same technique was used to vary the oxygen diffusion rate in sponges except that wire screens were inserted to suspend the sponges above the bottom of the cylinder. The dried sponges were placed in the containers and equilibrated for 24 h at a constant temperature of 21° C prior to the addition of water. The water was equilibrated by bubbling with the same oxygen concentration. A hypodermic syringe and needle were used to transfer enough water to the sponges to maintain suctions of 20, 30, and 40 mb. Oxygen diffusion rates increased rapidly as oxygen concentration increased from a partial pressure of less than 1 to 25 mm mercury (Fig. 2). There was little change in oxygen diffusion rate from a partial pressure of 25–144 mm mercury. Oxygen diffusion rates at 40 mb were nearly identical to those at 30 mb, however, those at 20 mb were slightly lower, indicating that 30 mb of suction —or more—were necessary for optimum diffusion.

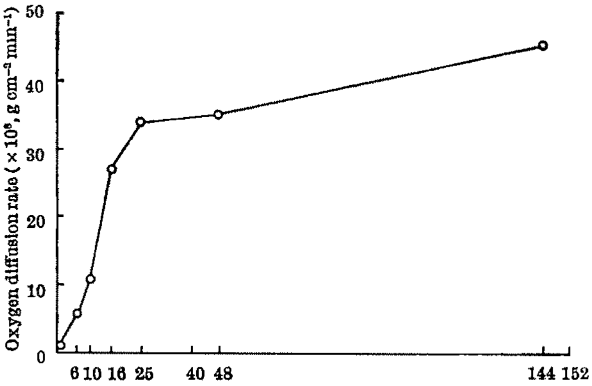

Fig. 2 Oxygen diffusion rates in pure cellulose sponges maintained at a moisture suction of 30 mb and exposed to different partial pressures of oxygen 21° C

Nematode investigations were conducted in 1 cm × 1 cm × 7 cm strips cut from large sponges. The sponge strips were washed in acetone and distilled water and dried at 60° C. The moisture suction of each sponge was adjusted by weighing and adding a calculated amount of water based on the water content–suction relationship in Fig. 1. Nematode suspensions of *Meloidogyne javanica* (Treub) Chitwood larvæ and *Hemicycliophora arenaria* Raski, all stages, were added to the sponge from a 1/2 ml hypodermic syringe. Nematodes were recovered from the sponge strips by cutting them into 1-cm cubes in sequence and placing in test tubes containing 10 ml of water. Since the sponges floated, gravity served as a natural separating force. Four replicate sponges were used in each treatment. One test was conducted on the recovery of *M. javanica* from sponge cubes in which 80 per cent of the nematodes were recovered in 1·5 h and 100 per cent in 3 h. Subsequent nematode determinations were made after a recovery time of 15 h.

Two tests were conducted to determine whether the nematodes were carried along the sponge in water currents set up by adding the nematode suspension to the sponge. Suspensions of *M. javanica* (17,000/0·5 ml) in one, and *H. arenaria* (1,300/0·5 ml) in the other, were syringed on the first cm of sponge strips. After 10 min the strips were cut into 1-cm cubes. Nematodes were not recovered from any of the cubes except that on which they were syringed. The sponge acted as a filter and held the nematodes in place while the water came to equilibrium in the sponge. Nematode suspensions in all subsequent tests were added in 0·05 ml of water to avoid any chance of nematode movement in the sponge.

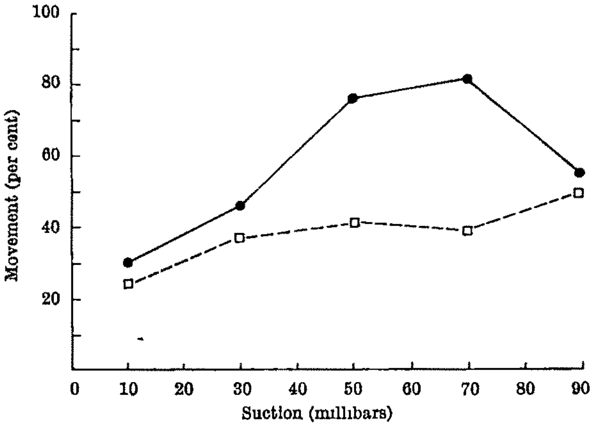

Fig. 3 Percentage movement of *M. javanica* larvæ and all stages of *H. arenaria* over a distance of 1 cm or more after 48 h in pure cellulose sponge strips of different suctions ●, *Meloidogyne javanica*, □, *Hemicycliophora arenaria* 27° C

The movement of *M. javanica* (2,200/0·05 ml) and *H. arenaria* (1,050/0·05 ml) was investigated in the sponge at suctions of 10, 30, 50, 70, and 90 mb maintained at 27° C for 48 h (Fig. 3). Optimum movement of *M. javanica* occurred at 50 and 70 mb and approximately 1, 3, 10, 22, 23, 19, and 21 per cent of the larvæ had moved 6, 5, 4, 3, 2, 1, and 0 cm, respectively. Movement of *H. arenaria* increased gradually from 10 to 90 mb, however, its total movements were less than *M. javanica*. The distribution of *H. arenaria* at 10–90 mb was 2, 3, 3, 4, 9, 28, and 51 per cent of the nematodes which had moved 6, 5, 4, 3, 2, 1, and 0 cm, respectively.

The effect of oxygen diffusion rate on nematode movement was studied at 50 mb of suction under a constant temperature of 21° C (Fig. 4). Although this temperature was not best for nematode movement, the oxygen diffusion rate of the sponge had already been determined at 21° C and a change in temperature would also change oxygen diffusion rate. Thus the percentage movement at 21° C was not so great as in the tests at 27° C. There was a linear relationship between movement of *M. javanica* (1,000/0·05 ml) and oxygen diffusion rate. The movement of *H. arenaria* (1,200/0·05 ml) was less responsive to oxygen diffusion rate than *M. javanica*. Observations in solutions bubbled with different oxygen concentrations indicated that there were no visible differences in movement of *H. arenaria* except at a partial pressure of 1 mm mercury where the nematodes were quiescent. Since this was a mixed population of all stages of the nematode, there may have been differences in susceptibility between larval stages and adults. Also the morphology of this nematode is quite different from *M. javanica* and may

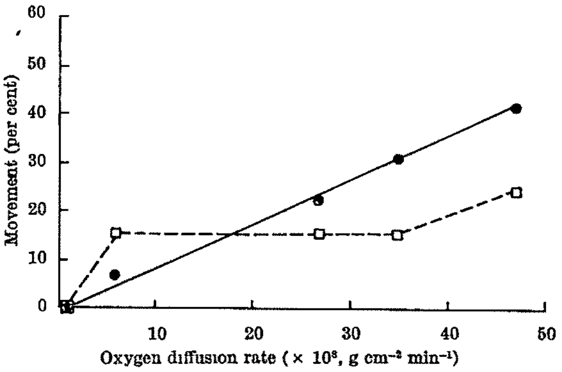

Fig. 4 Percentage movement of *M. javanica* larvæ and all stages of *H. arenaria* over a distance of 1 cm or more after 48 h in pure cellulose sponge strips maintained at different oxygen diffusion rates ●, *Meloidogyne javanica*, □, *Hemicycliophora arenaria* 21° C

account for the difference in responses to moisture and oxygen

Wallace[4] concluded from his studies that nematode movement in wet sand was optimum at the soil suction-level just sufficient to drain the pores Since this is also the point where air flows back into the soil pore spaces, oxygen could be responsible for the increased nematode movement It appears from the studies on *M javanica* larvæ that a sufficient supply of oxygen, as well as the proper moisture-levels, are essential for optimum nematode movement This effect of oxygen diffusion rate on movement may explain the reduction in secondary invasion of *M javanica* in tomato roots exposed to different oxygen concentrations[5] In the case of *H arenaria*, a nematode with a thick cuticle and heavy annules, there was little effect of moisture or oxygen on movement

The most important feature of this work was that the sponge proved to be a satisfactory substitute for soil in nematode–æration studies The thickness of the water films on the sponge surfaces and the oxygen diffusion rate in the water films can be easily determined and regulated *in vitro* The sponges may provide a synthetic medium useful for moisture and aeration investigations on other phases of the biology of nematodes, as well as for investigations on other organisms which reside in water films of soil

PHOSPHOLIPID BREAKDOWN IN BAKER'S YEAST DURING DRYING

By J. S. HARRISON and W. E. TREVELYAN

Research Division, Distillers Co , Ltd., Epsom, Surrey

SINCE the Second World War an increasing proportion of baker's yeast has been marketed in the form of the very stable, so-called active dried yeast This is made from a specially prepared yeast cake, which is reduced to pieces of suitable size and dried in a stream of warm air until its moisture content has fallen to about 8 7 per cent (dry weight basis), at which level the dried yeast is in equilibrium with an atmosphere of approximately 33 per cent relative humidity

When yeast of an appropriate strain is cultured in various ways and dried, the product, after rehydration by admixture with water (reconstitution), gives a suspension of cells which may ferment sugar at nearly the same rate as the undried culture More commonly there is some loss in activity. For yeast dried in the laboratory to a moisture content of 8 7 per cent we have found, using a standard test[1], losses ranging from 7 to 100 per cent This loss in activity is associated with a loss in low-molecular-weight constituents of the cell, which escape into the medium during reconstitution[2] As these constituents include nucleotides and similar substances, which absorb light strongly at a wave-length of 260 mμ, the extent of leakage during reconstitution can be measured simply and reproducibly by a spectrophotometric method using such a test we have found a close correlation between leakage and loss of activity We have made[3] a preliminary examination of the extracellular nucleotides present in a suspension prepared from dried yeast, using the technique of ion-exchange chromatography They do not apparently differ chemically from those found inside a normal yeast cell, though the proportions of the various nucleotides differ in the two cases in a way which suggests that molecules which are smaller or less highly ionized diffuse from the cell more readily It seems to be agreed[4] that the loss in activity is due to some change in the permeability of the cell membrane, caused by chemical changes occurring during drying, and/or a failure of the membrane to re-form properly or quickly enough when the dried cell is rehydrated[2]

When dried yeast is mixed with water, the activity of the resultant suspension depends very much on the temperature at which rehydration is carried out For maximal retention of activity the temperature must be carefully controlled at a level which is governed by the moisture content of the dried yeast In one case, the optimum temperature was found to range from 21° at a moisture content of 23 per cent to 42 5° at 5 8 per cent moisture Even with this precaution, loss in activity may be severe or even total if the nitrogen content of the yeast has been allowed to exceed a certain limit Thus, one strain of yeast was found to lose only 15 per cent of activity after drying and reconstitution, provided the organism had been grown in such a way as to restrict its content of total (Kjeldahl) nitrogen to 6 4 per cent However, at 8·3 per cent nitrogen 40 per cent activity was lost, while at 9 8 per cent nitrogen the suspension of rehydrated yeast was totally inactive

Clearly the activity of a suspension made from dried yeast will depend, not only on the loss suffered during drying and reconstitution, but also on the activity the yeast had before it was dried In general, for a given strain of yeast grown under specified conditions, this is positively correlated with the nitrogen content Consequently the plot of dried yeast activity against nitrogen content shows a maximum, usually in the region 6–7 per cent nitrogen content

Undoubtedly, many factors govern the extent to which activity is lost during drying, and the relative importance of one or other of these may depend on the nitrogen content It is, for example, possible that a variable proportion of the loss in activity associated with drying/rehydration is due to chemical or enzymatic reactions occurring during the initial phase of drying That enzymatic reactions do go on then is shown by the conversion of yeast cell glycogen to trehalose[5] Poor-drying, nitrogen-rich yeasts often darken considerably when dried this was at first considered to be evidence of a Maillard-type reaction, which might cause loss of activity, but the idea was discarded when it was found that yeast with a very high nitrogen content sometimes did not discolour, and when it was found that the cell-wall became thinner and perfectly transparent when dried, so that the colour of the interior parts of the cell might in any event be expected to become more obtrusive in the dried yeast

The extent of enzymatic degradation occurring when yeast is dried would vary according to the amount of the relevant enzyme present This again might well depend on the nitrogen supplied during propagation Such a situation was found to apply in the case of the inducible enzyme α-glucosidase (maltase), the content of which diminished, when yeast was grown with a restricted supply of assimilable nitrogen, far out of proportion to the fall in fermentation activity An autolytic enzyme with similar properties was suspected to be responsible for part of the loss of activity observed when high-nitrogen yeast was dried.

Preliminary work on the effect of drying on the carbohydrates, proteins, and nucleic acid of the yeast cell did not provide evidence of hydrolytic degradation of a type or magnitude commensurate with the observed losses in activity. We therefore directed our attention to the lipids of yeast, more especially as the cell membrane is thought to be largely composed of lipid material[6].

To determine total fatty acids and ergosterol in pressed yeast, a sample of the latter was refluxed with methanolic potassium hydroxide, which simultaneously saponified and extracted the lipids. These were partitioned into fatty acids and non-saponifiable lipid by conventional methods, after which ergosterol was determined by ultra-violet spectrophotometry and total fatty acids by weight and by titration with sodium hydroxide in ethanol. Dried yeast was first rehydrated before applying this procedure.

No decrease in the content of total fatty acids or of ergosterol was noted after yeast had been dried. The main use of this saponification procedure, in fact, was in testing methods designed to extract lipids from yeast in an undegraded form. To do this efficiently it was found essential first to disintegrate the yeast cells, which was done by shaking a thick suspension of yeast for 2 h with 2-mm diameter glass beads. After this treatment, the suspension was stirred with 15 vol. of chloroform/methanol 2 : 1 for 24 h. The washed cell residue contained only trace amounts of lipid, as shown by the failure of the saponification procedure to remove significant quantities of total fatty acids or of ergosterol.

The solvent, applied to whole yeast cells, extracted only about a quarter of the total lipid. Procedures based on a lengthy preliminary extraction with approximately 70 per cent ethanol, for example, Hanahan's[7], were abandoned because of some evidence of autolysis. For example, chromatography on silicic acid-impregnated paper[8,9] showed the ethanol extract to contain appreciable amounts of lysolecithin and lyso-phosphatidyl ethanolamine.

The chloroform/methanol extract of disintegrated yeast was washed without loss of lipid by the Folch technique[10], using 0.1 M sodium chloride. It was then evaporated, after which the lipids were taken up in ether and partitioned into phospholipids and neutral lipids by addition of acetone and a little magnesium chloride[11], which precipitated 92 per cent of the lipid phosphorus. Ergosterol and ergosterol esters, which were found to be entirely in the acetone-soluble fraction, were determined by spectrophotometry of the digitonin complex[12] precipitated before and after hydrolysis with methanolic potassium hydroxide. Fatty acids were estimated, as before, after saponification of one or other fraction. Phosphorus was determined after digestion with perchloric acid, and nitrogen by a direct Nesslerization procedure after digestion by the Kjeldahl method, using copper and selenium catalysts[13]. Information on the relative amounts of individual phospholipids present was obtained by paper chromatography. The phospholipid mixture was resolved by chromatography on silicic acid-impregnated paper, and in addition was subjected to mild alkaline hydrolysis[14] and the water-soluble glyceryl phosphoryl derivatives chromatographed on acid-washed paper. Yeast phospholipid was suspended in a 1 : 1 mixture of chloroform and methanol, methanolic potassium hydroxide was added, and the mixture shaken for 15 min at room temperature. The reaction was stopped by saturating the mixture with carbon dioxide. The upper layer obtained after addition of water was applied to the paper as such, or after conversion with ion-exchange resins to the free acids or ammonium salts.

Examinations of the effect of drying have so far been largely confined to yeast containing 8 per cent of nitrogen, which loses about half its activity as a result of dehydration followed by reconstitution. No evidence of hydrolysis of sterol esters could be found. The phospholipid fraction was found to have a fatty acid/phosphorus molar ratio of about 2 and a nitrogen/phosphorus ratio of about 1. After drying, the amount of phospholipid was found to have decreased by 10–20 per cent as shown by determinations of total weight, fatty acid and phosphorus. The fatty acid content of the neutral lipid fraction increased by a corresponding amount. In one case, in which the phospholipid phosphorus had fallen after drying from 53 to 43 µmoles/g dry weight, the chromatographic procedures showed that this was due to a decrease in the content of lecithin and of phosphatidyl ethanolamine. Analysis of the glyceryl phosphoryl derivatives after paper chromatographic separation showed that lecithin had decreased from 21 to 11 µmoles phosphorus/g. Phosphatidyl ethanolamine, but not phosphatidyl inositol, was also lost.

Similar changes in yeast phospholipids were induced by autolysis. After incubation with toluene for 5 h at 38° the yeast was extracted with chloroform/methanol without prior disintegration of the cells by shaking with glass beads, as the latter step was found, in the case of autolysed yeast, to be unnecessary. The phospholipid fraction had lost half its phosphorus and the major component was now phosphatidyl inositol (56 per cent), a finding which, incidentally, suggests the basis of a method for the preparation of this substance.

It appears, therefore, that when yeast of this type is dried even at moderate temperatures, the nitrogen-containing phospholipids are partially hydrolysed to diglycerides by a lecithinase resembling that described by Hoffmann-Ostenhof, Geyer-Fenzl and Wagner[15]. Yeast may also contain a phospholipase *A* and an acyltransferase, which, acting in conjunction, hydrolyse lecithin to glycerylphosphorylcholine and fatty acid[16]. However, we have found that the increase in free fatty acid associated with drying is much smaller than the loss of total fatty acid from the phospholipid fraction, which suggests that phospholipase *A* action plays a relatively minor part.

A sample of yeast of the same strain, as grown for drying and containing only 6.1 per cent nitrogen, lost less than 20 per cent of its activity when dried and reconstituted. The content of alkali-labile phospholipid was 33 µmoles phosphorus/g before drying and 34 µmoles/g after drying. Lecithin phosphorus was estimated to be 14 µmoles/g in both cases.

Thus the severe loss of activity, and high leakage, shown by high-nitrogen baker's yeast after drying and reconstitution may be due in part, in any event, to the action of a lecithinase *C* on the phospholipids of the cell membrane. The enzyme is either absent from low-nitrogen yeast or is not activated by drying.

A loss in lipid-bound choline associated with drying has been previously reported[17] for *S. cerevisiae* and *T. utilis*, though the technique of drying is not described.

SYNTHESIS OF BACTERIOCHLOROPHYLL BY *RHODOPSEUDOMONAS SPHEROIDES* UNDER DARK-AEROBIC CONDITIONS

By MASATAKA HIGUCHI and GORO KIKUCHI
Department of Biochemistry, Tohoku University School of Medicine, Sendai, Japan

COHEN-BAZIRE *et al* [1] found that, while the synthesis of bacteriochlorophyll by *R spheroides* cells was completely suppressed when the growing conditions were switched from the light-anaerobic to light-aerobic or dark-aerobic conditions by aeration, the synthesis could proceed even in the dark if the partial oxygen pressure was maintained at very low levels The dark semi-aerobic synthesis of bacteriochlorophyll by *R spheroides* was examined more precisely by Lascelles[2], who established the conditions which ensured that dark-aerobically grown cells formed bacteriochlorophyll rapidly in the dark We have found that the synthesis in the dark of bacteriochlorophyll in air by heavy suspensions of the dark aerobically grown *R spheroides* cells was markedly influenced, in terms of not only the rate of synthesis but also the intracellular status of the product, by the presence or absence of yeast extract or relatively high concentrations of iron in the incubation medium

R spheroides was grown dark-aerobically in the medium *S* of Lascelles[3] and the colourless cells were collected at an early stationary phase of culture The basal incubation medium used was similar to Lascelles's standard mixture[2] except that α-ketoglutarate was replaced by fumarate in our medium Collected cells were washed once and suspended in the basal medium so as to give a cell concentration of about 3 mg dry weight per ml The medium was supplemented with various additions according to the design of individual experiments 20 ml each of the suspension were placed in 100-ml Erlenmeyer flasks and incubated in the dark in air while being gently shaken (80 rev /min) at 30° Under these conditions, however, the oxygen pressure in the incubation mixture may be maintained at a considerably reduced level on account of the active respiration by the cells Synthesis of the pigment commenced without an appreciable lag period and proceeded at a constant rate, usually 6–8 h, until the chlorophyll-level reached maximum; this depended on the composition of incubation medium used Illumination had no effect on the rate of synthesis of bacteriochlorophyll under these conditions

The pigment formed was estimated spectrophotometrically by the method of Cohen-Bazire *et al* [1] In our basal medium, 1 5–3 μg of bacteriochlorophyll were synthesized per mg dry weight of cells at 6 h incubation under the conditions described (Table 1) The *R spheroides* strain used by us, however, excreted also a fair amount of porphyrin(s) when incubated in either Lascelles's standard mixture or our basal medium Similar phenomena were observed to occur by Lascelles when the dark-aerobically grown *R spheroides* cells were incubated semi-aerobically in the dark[2] or anaerobically in the light[4] in a medium containing no or little iron

The addition of yeast extract (Difco) into the basal medium resulted in marked increase in the synthesis of bacteriochlorophyll (Table 1, Exp 1) and suppression of accumulation of porphyrin A similar effect was observed also, even when Lascelles's standard mixture was used The stimulative effect of yeast extract cannot be attributed to such components in the extract as amino-acids, vitamins and nucleotides since the addition of casamino-acid, vitamin mixture and hydrolysates of yeast ribonucleic acid, separately or together, did not appreciably increase the yield of bacteriochlorophyll under comparable conditions (Table 1, Exp 1) The addition of casamino-acid however, resulted in considerable cell growth during incubation The optimal concentration of yeast extract to bring about the maximum synthesis of bacteriochlorophyll falls in the range 0 25–0 5 per cent It was also found that synthesis of bacteriochlorophyll was greatly stimulated by supplementing the basal medium with additional ferric citrate (Table 1, Exp 2) The optimal concentration of ferric citrate to be added was about 0 5 μmole/ml Manganese showed a similar effect but to a lesser extent These findings tempted us to measure the iron content in yeast extract, but the value found was too small to attribute the effect of yeast extract to the iron in it The stimulative effect of yeast extract was reduced to less than half the original activity by treatment with charcoal The iron content in the extract was also reduced considerably by the same treatment. The possibility remains that the yeast extract contains some organic iron compounds which may be responsible for the observed effect of yeast extract Carotenoid synthesis was also increased by these supplements (Fig 1)

Significant differences were noticed between the absorption spectra of cell extracts, particularly in the near infra-red region, according to whether the bacteria were incubated with or without yeast extract or ferric citrate (Fig 1) Cell-free extracts of *R spheroides* were prepared by 3 min sonication followed by 30 min centrifugation at 7,000*g* The extract of the cells incubated in the iron-free medium showed small absorption peaks of chlorophyll at 880 mμ and 590 mμ (Fig 1, *A*), while the extract of the cells incubated in the medium supplemented with 0 5 μmoles/ml of ferric citrate or 0 25 per cent yeast extract gave the chlorophyll peaks at 590, 800 and 850 mμ

Table 1 EFFECTS OF YEAST EXTRACT, FERRIC CITRATE AND OTHER FACTORS ON THE SYNTHESIS OF BACTERIOCHLOROPHYLL IN *R spheroides* AND THE CELL GROWTH

Additions	Final conc	Bacteriochlorophyll formed μg/ml medium	Bacteriochlorophyll formed μg/mg dry wt	Growth* mg dry wt of cells/ml medium
Exp 1				
None		7 7	2 6	+0 1
Casamino-acid	0 5%	9 6	2 4	+0 8

Inorganic salts solution	10%	22 2	7 7	−0 1

* As measured by the optical density change at 680 mμ (ref 1)

Dark aerobically grown cells were suspended (3 mg dry wt /ml) in the basal medium supplemented with various additions as shown in the Table and incubated aerobically in the dark for 6 h at 30° Casamino-acid used was a commercial vitamin-free casein hydrolysate In this experiment the medium was also supplemented with 100 μg/ml each of L-tryptophan, L-cystine and DL-methionine Vitamin mixture solution used contained in 1 ml 2 mg each of thiamine, nicotinamide and pyridoxine, 5 mg of sodium pantothenate, 3 mg of riboflavin, 75 mg of ascorbic acid, 500 μg of biotin, 2 μg of vitamin B_{12}, 5,000 I U of vitamin A, 500 I U of vitamin D and 25 mg of L-lysine hydrochloride Acid hydrolysate of yeast RNA was prepared by hydrolysing a commercial yeast RNA sample with 1 N hydrochloric acid at 95° for 1 h and used after being neutralized with sodium hydroxide Inorganic salts solution used contained in 1 ml 1 μmole of $MnCl_2$, 2 μmoles of ferric citrate and 100 μmoles of phosphate buffer (*p*H 6 8) with a shoulder at 870 mμ (Fig. 1, *B* and *C*). In Fig. 1, *A*, also a peak at 423 mμ can be seen which is probably due to porphyrins. The spectrum of the extract of the cells incubated in the basal medium (which contained 0.01 μmole/ml of ferric citrate) comes in between the two types of spectrum cited here (Fig. 1, *D*). In spite of these marked spectral differences between extracts obtained from the cells incubated under different conditions, when the chlorophyll spectrum was examined after being extracted into methanol–acetone from the cells, no significant difference could be observed between those differently incubated cells; all the samples examined gave the typical bacteriochlorophyll spectrum showing a maximum at 770 mμ. These results indicate that the structure of bacteriochlorophyll itself has not been affected by the supplement of iron or yeast extract to the incubation medium. In contrast, it is highly probable that these additions had a profound influence on the status of bacteriochlorophyll in the living cells which presumably is dependent on some interactions of bacteriochlorophyll and other intracellular components.

Although the chlorophyll content in cells and the optical densities at 800, 850 and 800 mμ in cell-free extracts varied significantly according to incubation conditions when examined at 6 h incubation, the values of *E* 850 mμ/*E* 880 mμ and *E* 800 mμ/*E* 880 mμ (*E* stands for optical density) were found to increase linearly and in parallel with each other with the increase in chlorophyll content (Fig. 2). The values, however, were more or less variable in separate experiments. These results suggest that the component which gave an absorption maximum at 850 mμ (850 mμ component) may possess an additional absorption at 800 mμ. Or the 800 mμ peak may be an indication of a third component which could grow up in parallel with the formation of 850 mμ component. We have observed that when the cells were collected at an earlier phase of incubation in the medium rich in iron or yeast extract, the chlorophyll spectrum of the cell extracts was quite similar to that of cells collected at a later phase of incubation without the supplements. Moreover, when the dark-aerobically grown cells were pre-incubated for 2 h in the medium rich in iron, then washed and transferred to the iron-deficient medium, the same cells continued actively to synthesize bacteriochlorophyll even in the latter medium, giving rise to the formation of 850 mμ component as the major product. Either of these bacteriochlorophyll components in extracts of *R. spheroides* cells can be sedimented almost completely by 90 min centrifugation at 105,000*g*. This indicates that all of them are bound to chromatophores.

Considering these experimental findings, we are inclined to assume that the synthesis of bacteriochlorophyll in question would proceed in the following fashion: at earlier stages of incubation, the rate of 880 mμ component formation far exceeds that of 850 mμ component formation, but the rates change gradually during incubation, and at later stages the 850 mμ component is synthesized much more actively than the other, and this step may be sensitive to iron or some unknown components in the yeast extract.

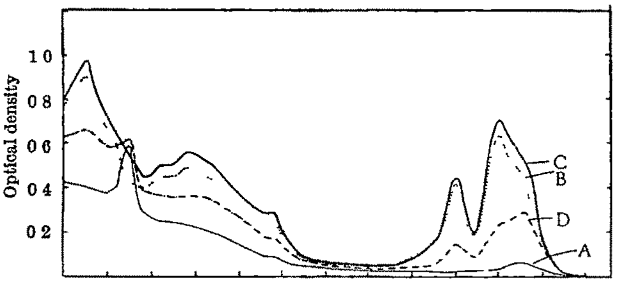

Fig. 1. Absorption spectra of the cell-free extracts of *R. spheroides* incubated dark-aerobically with or without yeast extract and ferric citrate in the medium. 20 ml. each of the suspension of dark-aerobically grown cells (2.1 mg dry wt./ml.) were incubated aerobically in the dark for 6 h at 30°. The composition of the ordinary basal incubation medium (containing originally 0.01 μmoles/ml. ferric citrate) was changed in individual experiments shown in the figure in the following way: (*A*) minus iron, (*B*) plus ferric citrate up to 0.5 μmole/ml., (*C*) plus 0.25 per cent yeast extract, (*D*) no change

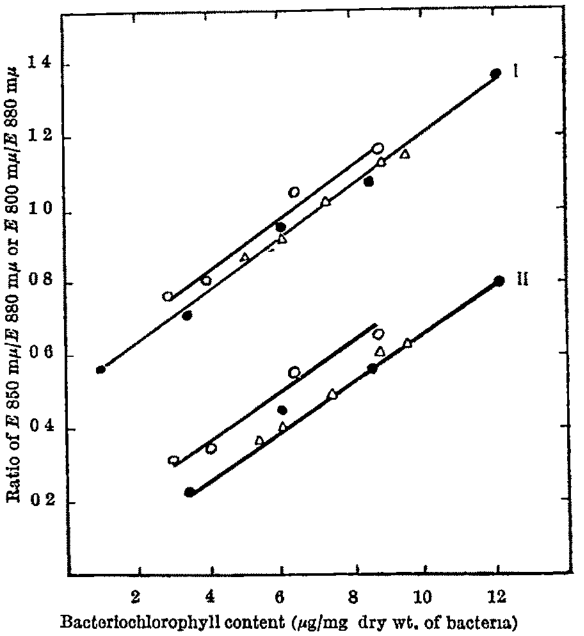

Fig. 2. Change of the values of *E* 850 mμ/*E* 880 mμ and of *E* 800 mμ/*E* 880 mμ as a function of the bacteriochlorophyll content in the *R. spheroides* cells. I, *E* 850 mμ/*E* 880 mμ; II, *E* 800 mμ/*E* 880 mμ. Experimental conditions were similar to those in Fig. 1, except for the composition of incubation media used. Values represented by ● in the figure were obtained by a series of experiments in which the basal media supplemented with various amounts of ferric citrate were used; ○, supplemented with yeast extract, treated or untreated with charcoal or ion exchange resin ('*IR* 120-H' type); △, pre-incubated in media poor or rich in iron, then transferred respectively into second media containing different amounts of iron from those used for pre-incubation

In vivo spectrum of bacteriochlorophyll in photosynthetic bacteria has been shown to vary according to the influence of various factors such as the light intensity during the growth of organisms[1,5], heat shock[5], cooling at liquid nitrogen temperature[9], and genetic variations of the bacteria[7], and various interpretations have been given with respect to the differences in *in vivo* status of bacteriochlorophyll[5-9].

Although the present investigation could not reveal which of these speculations is the more valid, our findings that the synthesis of 850 mμ component was more susceptible to the amount of iron or yeast extract in the incubation medium would provide an experimental way of controlling the *in vivo* status of bacteriochlorophyll. Such an approach may facilitate the solution of the role in bacterial photosynthesis of each chlorophyll component as distinguished by the infra-red absorptions of cell extracts.

We thank Dr. T. Mizuochi, Department of Agricultural Chemistry, Faculty of Agriculture, Tohoku University, for his advice.

LETTERS TO THE EDITOR

RADIOASTRONOMY

Radio Frequency Radiation from Cygnus *Y*

DURING mapping observations of radio source *HB*21 at 600 Mc/s using the new 260-ft. radio telescope[1] here, a highly complex region of radio radiation was revealed between declination −49° and + 51° extending from right ascension 20 h 30 m to 21 h 50 m. The region is situated about 8° north-east of the well-known radio source[2] Cygnus *X*. The new region, like Cygnus *X*, contains an unusual number of separate discrete radio sources of various sizes, and will be referred to as Cygnus *Y*.

The present observations were made at 600 Mc/s. The antenna has half-power beam-widths of 24 min by 80 min of arc in right ascension and declination, respectively. The effective collecting aperture of the antenna is 870 m². A sample record of the drift curve, obtained at declination + 50°, is presented in Fig. 1, which shows the presence of six discrete radio sources of various angular sizes superimposed on the slow rise due to the general galactic background radiation.

These sources are listed in Table 1. The present observations have verified all the 3*C* and *CTB* sources in the region; thus the previous discrepancies between the 3*C* and *CTB* sources have been clarified. The source *CTB*104 was resolved into two separate components (see sources *D* and *E* in Fig. 1). The flux density given in Table 1 refers to the observed peak flux density rather than the integrated flux density. The integrated flux density cannot be determined until the radio mapping of the whole region is completed.

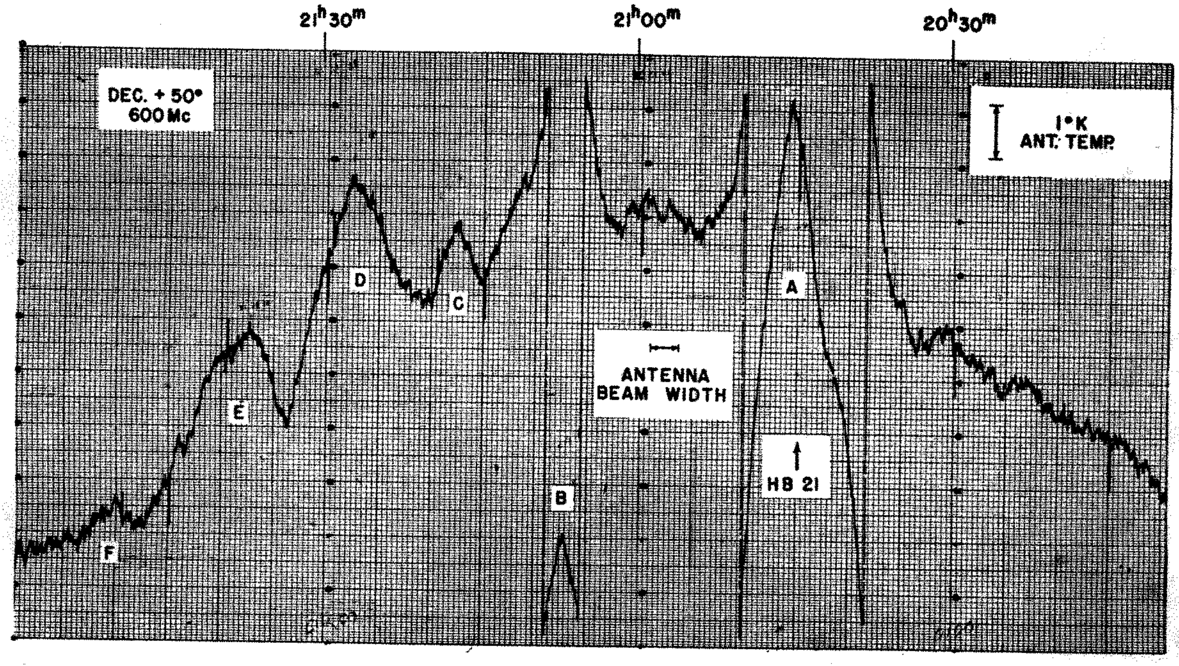

Fig. 1. Sample record of an observation taken at declination + 50°

A high-resolution radio map containing the Cygnus *Y* region was first made by Hanbury Brown and Hazard[3] at 158 Mc/s using a 2° antenna beam. They discovered the extended source *HB*21. A recent radio map of the same region made by Wilson and Bolton[4] at 960 Mc/s using a 0·8° antenna beam shows three discrete sources (*CTB*97, *CTB*101 and *CTB*104). Interferometric surveys of the region made at Cambridge[5,6] at metre wave-lengths show three discrete sources in the region (3*C*420, 3*C*428 and 3*C*431). However, the agreement among these sources is rather poor except for sources *HB*21 (same as 3*C*420 and *CTB*97) and 3*C*428 (same as *CTB*101).

Table 1

Source No.	Position (1950.0) Right ascension	Position (1950.0) Declination	Peak flux density 10^{-26} W m^{-2} $(c/s)^{-1}$	Angular size	Remarks
A	20h 45m 04s ± 10s	+ 50° 30′ ± 10′	46·9	1·9°	*HB*21 3*C*420, *CTB*97
B	21h 06m 54s ± 10s	+ 49° 45′ ± 10′	16·3	0·7°	3*C*428, *CTB*101
C	21h 17m 10s ± 10s	+ 49° 25′ ± 10′	6·7		3*C*431
D	21h 27m 11s ± 10s	+ 50° 30′ ± 10′	15·8	1·5°	*CTB*104
E	21h 37m 00s ± 10s	+ 50° 10′ ± 10′	7·8	1°	*CTB*104
F	21h 50m 24s ± 15s	+ 50° 15′ ± 15′	1·5		

The profile of source *A* in Fig. 1 clearly shows an unsymmetric structure. A further observation of the source at 1,400 Mc/s using an 11-min arc antenna beam has resolved the source into at least three components. This source has been identified with a supernova remnant[7]. Sources *B*, *D* and *E* are all extended sources of the order of one degree, and appear to have fine structure. There is a suggestion that source *E* consists of two components.

The Cygnus *Y* region, like Cygnus *X*, is one of the interesting and unusual parts of the sky because of its high source density and the complex structure. The region is now being mapped in detail at 600 Mc/s and 1,400 Mc/s to obtain the spectrum of the individual sources as well as the detailed structure of the region.

ASTRONOMY

Spectra of Meteor Wakes

With regard to the interesting communication by Rao and Lokanadham[1] I would direct attention to a possible consequence.

Hoffmeister[2] has collected various instances of auroral-like glows connected with meteoric showers, Perseids, Leonids, 1872 Bielids. Such was also noted in Germany and England during the famous Leonid shower of November 13–14[3]. It was indeed remarked it might be possible that "brilliant meteor streams electrify the higher regions of the atmosphere and produce phenomena analogous to the aurora borealis"[4].

The detection of *H* and the red line of *NI* is interesting in view of the observation by von Wrangel in Siberian waters 1820–24[5] that dark areas of aurora traversed by meteors lighted up and continued to glow.

[5] Dauvillier, A., *Les Aurores Polaires* (Alcan, Paris, 1954).

Miss Botley has brought to light some interesting observations of auroral-like glows of meteors during some meteoric shower periods[1–3] and during periods of auroral activity[4]. These observations indicate that this phenomenon is associated with the atmosphere, in which meteors appear, being in an ionized or excited condition. There is evidence for such a general increase of electron density in the *E* region during meteoric shower periods[5]. It is also known that the atmosphere above 80 km is ionized by auroral activity[6]. The predominant constituents of the atmosphere in this region are atomic oxygen and molecular nitrogen[7].

The main contributing feature in the auroral-like glow of meteors appears to be the forbidden line of *OI* (λ5577, known as the auroral green line), which has been observed in as many as 30 meteor spectra[8–10]. A possible explanation for the production of this line by a combination of the oxygen contained within the meteoroid and that in the atmosphere has been outlined by Halliday[11]. From the observations of Halliday, Millman[8] concluded that even moderate solar activity was not necessary for this green line to appear in meteor spectra. This is consistent with the foregoing picture that the increase of atmospheric ionization above normal may also be produced by meteor showers, like auroræ which occur during periods of high solar activity.

The appearance of the weak $H\alpha$ and *NI* lines in meteor spectra[10] may be mainly due to these elements present within the meteoroid particle. The mechanism of production of the former line may be similar to that in auroræ, wherein the same line is produced by protons of the corpuscular radiation from the Sun[12]. It may be noted in this connexion that the nitrogen bands observed in the red and yellow regions of the meteor spectrum by Cook and Millman[13] were connected with the molecular nitrogen in the atmosphere.

The foregoing explanation of auroral-like glow of any meteor is based on the fact that it is caused by the further local excitation of the atmospheric gases, already in a sufficiently excited condition, by the passage of the meteor through them. Such a glow should reveal itself in the wake spectrum of the meteor, as did the oxygen green line[8–10]. On the other hand, the $H\alpha$ and *NI* lines are found only in the primary spectra[10,14] of meteors.

PHYSICS

Intensity of Neutral Argon Emission Lines radiated by the Low-voltage – High-amperage Arc compared with Four High-voltage Type Arcs

The intensity of strong neutral argon emission lines radiated by the thermally excited argon shield gas surrounding and within the central d.c. arc plasma of the Heliweld thoriated tungsten electrode welding arc has been measured. This arc was operated at 15 V and 135 amp (d.c.), providing a good source for thermally exciting neutral argon emission lines at a voltage below the ionization voltage (argon = 15·8 V).

The purpose of the investigation was to see how the relative intensities of the strong neutral emission lines of argon varied in reference to each other for this thermally excited arc compared with microwave, glow discharge and hollow cathode type arcs. This information should add to the background of data on observations of spectral sensitivity of elements excited under varied conditions.

As W. F. Meggers[1] points out, the relative intensities of lines in any particular spectrum are fairly independent of conditions; successive spectra will show large differences as functions of excitation conditions. In order to get the best comparison of intensities between arcs, therefore, the intensities are normalized to the strongest line common to all arcs. The intensities for each arc and intensity values are then adjusted by ratio to this normalized intensity value (0·8115μ argon line) as shown in Table 1.

The values recorded for the tungsten arc were recorded by a Perkin–Elmer monochromator with suitable entrance optics and output recorder.

Table 1 shows the normalized intensity values for all these arcs. The low-voltage tungsten arc emission lines appear to differ in intensity to the same degree as the microwave, glow discharge and hollow cathode intensities vary from each other.

Table 1. RELATIVE INTENSITIES OF ARGON EMISSION LINES EMITTED BY A LOW-VOLTAGE HIGH-CURRENT ARC COMPARED TO THREE HIGH-VOLTAGE LOW-CURRENT ARCS

Wave-length (μ)	Low-voltage tungsten arc*	Microwave excitation†	Glow discharge (60 a.c.)‡	Hollow cathode discharge§

0·9123	212	415	—	361
0·9224	145	217	—	155
0·9658	126	290	—	229

* Tungsten arc 135 amp, 15 V, atm. pressure. 16 cm ft./h argon flow.

† Microwave excited, end view, 6·5 mm pressure, *Amer. Inst. Phys. Handbook*, 7–68.

‡ Glow discharge 60 cycle a.c., 60 m.amp, 3 mm pressure, *Amer. Inst. Phys. Handbook*, 7–61.

§ Hollow cathode discharge, iron electrodes, 150 m.amp, 1 mm pressure, *Amer. Inst. Phys. Handbook*, 7–61.

Table 2 gives the ratio of the tungsten arc to the other arc intensities for the various emission lines. It is apparent, even though all the intensity scales for each arc are normalized to the strong 0·8115μ argon line, that the same wave-length lines do vary from each other to a large degree from arc to arc.

Table 2. INTENSITY RATIOS OF ARGON I EMISSION LINES OF THE LOW-VOLTAGE TUNGSTEN ARC TO THE HIGH-VOLTAGE ARCS

λ (μ)	Energy-levels	Tungsten arc to microwave	Tungsten arc to glow dis.	Tungsten arc to hollow cath.
0·6965	$1S_5-2p_2$	0·95	0·88	1·82
0·7067	$1S_5-2p_3$	1·16	1·03	1·88
0·7273	$1S_4-2p_2$	1·85	1·32	4·00
0·7384	$1S_4-2p_3$	1·03	1·61	1·56
0·7515	$1S_4-2p_5$	1·35	1·70	1·70
0·7635	$1S_5-2p_6$	1·24	0·99	1·47
0·7724	$1S_5-2p_7$	0·69	0·59	1·04
0·7948	$1S_3-2p_4$	0·95	1·28	1·28
0·8006	$1S_4-2p_6$	1·22	1·16	1·72
0·8115	$1S_5-2p_9$	1·00	1·00	1·00
0·8265	$1S_2-2p_2$	0·43	0·56	0·92
0·8408	$1S_2-2p_3$	0·62	0·93	0·95
0·8425	$1S_4-2p_8$	0·73	1·04	0·77
0·8521	$1S_2-2p_4$	0·46	0·72	0·81
0·8668	$1S_3-2p_7$	0·51	1·05	0·79
0·9123	$1S_5-2p_{10}$	0·51	—	0·59
0·9224	$1S_2-2p_6$	0·67	—	0·93
0·9658	$1S_4-2p_{10}$	0·44	—	0·55

It would appear that, even taking into account the rough accuracy of these intensity values, the intensities between one line and another for each arc are not the same for different types of excitation. This cannot be attributed entirely to pressure differences between arcs since the tungsten low-voltage arc at atmospheric pressure did not vary from the other arcs for any particular emission line any more than the glow discharge arc at 3 mm pressure varied from the hollow cathode arc at 1 mm pressure. It is obvious that the electron temperatures are different between these arcs, and this is probably the main factor in determining the intensity ratios for various wave-length lines compared with the strong 0·8115μ line.

Table 3. SHIELD GAS ENVELOPE VERSUS CENTRAL TUNGSTEN ARC ARGON LINE INTENSITIES

Wave-length (μ)	Ratio of shield gas glow to central arc intensity lines
0·7504	0·127
0·7515	0·138
0·7635	0·216
0·7724	0·127
0·7948	0·145
0·8006	0·101
0·8115	0·154
0·8265	0·254
0·8408	0·282
0·8425	0·248
0·8521	0·223
0·9123	0·625
0·9224	0·500

The intensity of the argon lines emitted at the outside edge of the tungsten arc shield gas envelope were measured. The intensities of these lines were compared with those emitted by the central arc and are given in Table 3.

In this experiment the intensity ratios of the 0·9123μ and 0·9224μ lines show a definite increase in intensity for the glowing shield gas envelope. This would indicate a definite increase of emission intensity for the $1S_5-2p_{10}$ (0·9123μ) and $1S_2-2p_6$ (0·9224μ) energy-levels for the outside glowing shield gas envelope. This emitting portion of the arc is obviously at a lower temperature than the central arc column.

Difficulties in obtaining Uniform Dose Distribution throughout Electron-irradiated Plastic Mouldings

THE published ranges of fast electrons and the associated depth/dose curves have been measured in slabs of material irradiated with initially mono-energetic electrons. Such figures give an indication of the maximum thickness of bulk material which can be usefully irradiated with an electron beam of a particular energy.

In practice, objects to be irradiated would probably be complicated mouldings with inserts of various materials rather than homogeneous large slabs. Such mouldings give rise to a variable depth/dose relationship due to non-complementary scattering from discontinuities. Electrostatic repulsion may be a factor in this effect.

By examination of the scatter and absorption images produced on a paper with a radiation-sensitive coating, it has been shown that very large differences in absorbed dose are indicated on a complex moulding irradiated in a mono-energetic unidirectional electron beam. The thickness of material presented to a 4-MeV electron beam was nowhere greater than 50 per cent of the range as measured using the same beam with a slab of material. Irradiation from both sides of the sample reduced the spread of indicated dose by a factor of approximately two, leaving the ratio of maximum to minimum doses about 3 to 1. This would involve serious over-dosing and inefficiency in cases where a specified minimum dose is required.

The original work on the problem of uniformity of dose throughout a plastic moulding was done using self-adhesive paper with a radiation-sensitive coating developed by Vale and Farrell[1] as an indicator label for radiation-sterilized articles.

The colour change on the indicator label paper with increasing dose was from yellow through orange to red. This gave satisfactory dose discrimination for the first experiments, but as the dose ratio was reduced by techniques described later, greater resolution was required. Vale and Farrell, by an alteration in the sensitive dye used in the coating, produced a paper that changed from bright green through brown to purple and then pink. Since four definite colours and their associated transition shades covered only 3 × 10^6 rads, quite good dose estimation could be obtained by visual inspection.

It has been shown by Trageser[2] that a forward-scattering foil in the electron beam path degrades the mono-energetic stream and the lower energy components produced almost eliminate the dose build-up at the front face of a sample.

At this laboratory a foil has been used not only to degrade the electron beam energy but also to produce a multidirectional effect. In order to obtain the greatest effect from the foil it needs to be as close as practicable to the moulding.

Further reduction in the dose ratio was obtained by utilizing back-scattered electrons from the sample support.

As expected, the number of back-scattered electrons was increased by increasing the atomic number of the backing plate and, as with the forward scatter foil, the widest scatter angles were presented to the moulding at the closest practicable distance.

The best results were obtained using a forward scatter foil of 0·5 mm aluminium and a back scatter plate of 1·5 mm lead over the sample support tray.

Final dose distribution checks were made using the improved indicator paper above, below, and inside the moulding. The dose ratio within the moulding irradiated from one side was then found to be 1·2.

Owing to the increase in overall efficiency on using the scattering foils, the minimum indicated dose under the conditions quoted was close to the mean exposure dose as measured in the first 1·2 g/cm^2 of a slab of material irradiated by the 4-MeV beam without scattering foils.

Dielectric Loss Factor of Polytetrafluoroethylene under Irradiation

The effect of ionizing radiation on steady-state conductivity of polymeric dielectrics has been already examined by several authors. I have shown[1] that radiation affects not only the steady-state conductivity of polytetrafluoroethylene but also the transient conductivity, deduced from the current flowing through the specimen after the application of d.c. voltage. Recently I have carried out measurements of dielectric permittivity and dissipation factor under irradiation.

As a source of radiation, an X-ray equipment was used, giving dose rates in the range 0·01–100 r./sec. Circular specimens, 40μ thick, were cut from commercial polytetrafluoroethylene sheet and aluminium electrodes were evaporated on to both sides. A 'sandwich' type arrangement of two specimens was used. The dielectric permittivity and dissipation factor were measured at 50 and 1,000 c/s, 100 V and at about 21° C by the aid of a Wien's bridge (the four capacitances bridge) provided with a Wagner's earth.

The effect of radiation on the dissipation factor of polytetrafluoroethylene is much less pronounced than on the steady-state conductivity. The dissipation factor begins to rise at 50 c/s with a dose rate of 1 r./sec, at 1 kc/s even with 10 r./sec. The dielectric permittivity remains nearly constant in the whole range of dose rates used. From these a.c. measurements the loss factor was deduced. Fig. 1 shows the dependence of loss factor on dose rate over the range 0·01–100 r./sec. The loss factors at low frequencies were deduced from d.c. measurements[1] by Hamon's method[2]. The results indicate that the variation in the loss factor with dose rate is not caused solely by the rise of steady-state conductivity.

Heat Liberation in Alloy-junction Silicon Diodes

In a recent communication[1], Melehy and Jarmoc have reported interesting observations of the distribution of temperature in silicon diodes carrying a relatively large current in the forward direction. It is shown here that their observations are readily explained in terms of junction theory, when account is taken of the difference in electron and hole mobilities in silicon.

Consider a p^+–n–n^+ structure biased sufficiently in the forward direction so that the injected carrier density in the n-region is greater than the equilibrium density of electrons, and there are equal densities of electrons and holes[2]. When the width of the n-region is comparable with the diffusion length, recombination of electrons and holes is known to occur[3] predominantly in the end regions, at the metal-semiconductor contact.

For convenience we consider the end regions to be degenerate. An electron which surmounts the potential barriers between n^+- and n-regions, and between n- and p^+-regions, extracts heat[4] from the system at these two planes; the total energy abstracted per electron is to a first approximation $q(E_g - V_f)$, where qE_g is the band-gap energy and V_f the forward bias voltage on the diode. On arrival in the p^+-region the electron recombines with a hole and liberates energy qE_g, which may be assumed to be taken up by the lattice as heat energy. We neglect the kinetic energy of the charge-carriers, as well as heat dissipation associated with the flow of current in the n-region.

In the same way there is a transfer of heat energy by holes from the p^+–n and n–n^+ junctions to the n^+-region. However, because the electrons have greater mobility in the electric field which exists in the n-region, and the densities there are equal, the electron current in the device will exceed that of the holes; the transfer of heat energy to the p^+-region will therefore outweigh that to the n^+-region in the ratio $b \simeq 2{\cdot}8$ at room temperature, and we may expect the temperature in the p^+-region to rise above that in the n^+-region, as observed[1].

Furthermore, if the mobility ratio b is sufficiently large the heat extracted by electrons in the vicinity of the n^+-region may exceed that liberated by holes arriving there, and the temperature at this side of the diode will fall below the ambient. With a suitable semiconductor (for example, indium arsenide) a p^+–n–n^+ structure may thus act as a thermoelectric refrigerator by virtue of the flow of non-equilibrium charge-carriers.

METALLURGY

Recrystallization and Grain Boundary Sliding in a Magnesium Alloy

During tensile deformation of magnesium and its dilute alloys in the temperature range 100°–350° C, cells form preferentially close to the grain boundaries[1]. Afterwards irregular boundary migration occurs and evidence has been presented for the grain boundaries being pinned at their intersections with the cell walls[2]. This migration results in an increase in grain boundary area and thus the driving force must arise from the difference in stored energy between neighbouring grains. It is unlikely that sliding can occur to any appreciable extent at these irregular boundaries and in these circumstances it is probable that the shearing forces in the vicinity of the grain boundaries are accommodated by increases in the degree of misorientation across the cell walls. Eventually the irregular migration leads to primary recrystallization[2-6] along the old grain boundaries and an example is illustrated in Fig. 1.

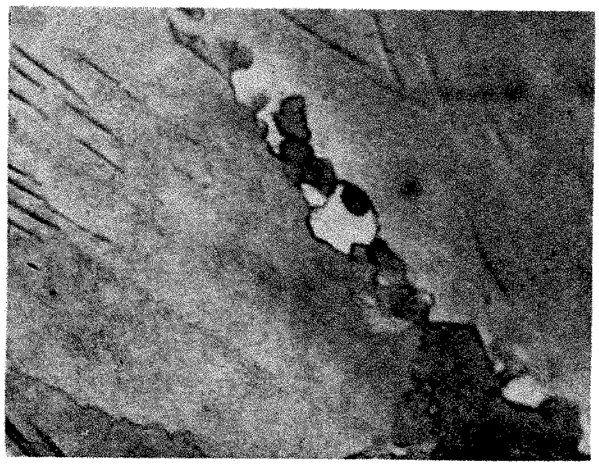

Fig. 1. Specimen deformed to failure at a rate of 0·1 per cent/h at 200° C. A network of new grains has formed along the old grain boundaries (× *c.* 270)

Stacey[3,4] has suggested that the observed increase in tensile ductility with decreasing strain rate of a magnesium/0·8 wt. per cent aluminium alloy at 150° C is due to such primary recrystallization. On the other hand, Greenwood *et al.*[7] and Brookes *et al.*[8] attribute similar increases in ductility to non-basal slip systems becoming operative preferentially at the slower rates.

Primary recrystallization is *per se* a recovery process and its occurrence would relieve stress concentrations at the original grain boundaries. In addition, ductility may be improved by sliding occurring at the new grain boundaries; it was to test this latter possibility that these experiments were carried out.

A 0·06-in. thick sheet specimen of a magnesium/0·8 wt. per cent aluminium alloy was polished chemically, deliberately scratched using 6μ diamond paste and then pulled to fracture at a rate of 0·1 per cent/h in air at 200° C. As a consequence of continuous migration and recrystallization during deformation there was no clear evidence for sliding at the new grain boundaries. Accordingly, a mixed strain-rate test was carried out. A similar specimen was polished and scratched as before and then deformed 15 per cent at a tensile rate of 18 per cent/h and a further 10 per cent at a rate of 180 per cent/h at 300° C. The initial slow deformation had resulted in a network of new grains being formed along the original grain boundaries and the subsequent rapid rate was used to minimize boundary migration during the second part of the test.

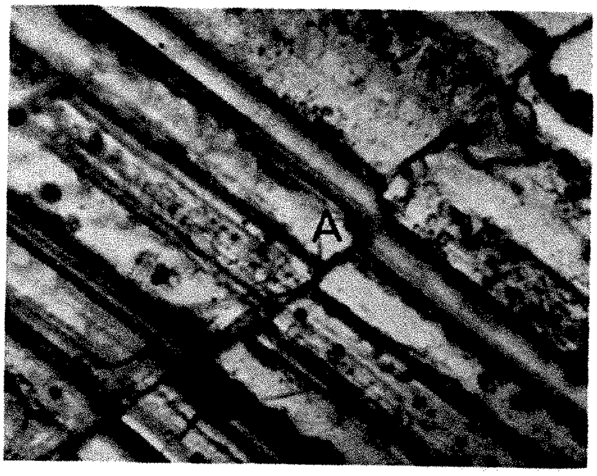

Fig. 2. Mixed strain-rate specimen deformed at 300° C. Where the fiducial lines cross the location of the old grain boundary two distinct steps are seen, for example at *A* (× *c.* 1,070)

Evidence for sliding at the new grain boundaries is presented in Fig. 2. Where the fiducial lines cross the locations of the old grain boundaries they show two distinct steps, for example at *A* (Fig. 2). This result lends support to the suggestion that primary recrystallization leads to improved tensile ductility.

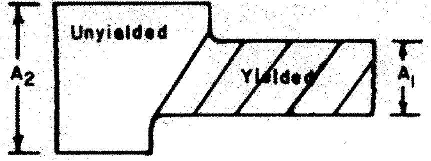
A Method of Determining the Stress Effective during Lüders Band Propagation

In materials which exhibit a well-defined yield-point drop followed by non-uniform yielding at a nearly constant stress, this stress is given by the Petch equation[1] as:

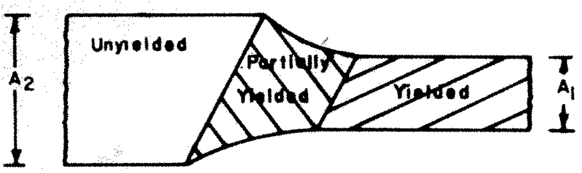
$$\sigma_y = \sigma_i + k_y d^{-\frac{1}{2}} \tag{1}$$

where σ_y is the lower yield stress, σ_i is the friction stress, k_y is a term originally thought to be associated with an unlocking stress and $2d$ is the grain diameter. It is desirable to have an accurate value of the macroscopic stress, σ_y, in order that the slope of the lower yield stress vs. grain size curve, k_y, be as meaningful as possible. In addition, the dependence on temperature of the lower yield stress is an important property in theoretical considerations. Difficulties may arise, however, in determining what value of the lower yield stress to use in such situations. This communication describes a method which can be used to determine, at least in an approximate manner, whether the magnitude of any corrections to the nominal yield stress is sufficiently large to warrant consideration.

One source of error is that due to the change in cross-sectional area as one proceeds from the yielded to unyielded material in a specimen. The magnitude of this effect can be rather large for a small grain size[2] or at low temperatures[3]. Change in area can be taken into account by using the value of the Lüders strain to calculate the area behind



(a) Very sharp front



(b) Diffuse front

Fig. 1. Sharp and diffuse Lüders band fronts in a tensile specimen

the front, but this procedure will result in an overestimate of the stress because the Lüders front is normally more or less diffuse. Fig. 1 illustrates two types of Lüders fronts. In Fig. 1*a* the stress causing flow is increased by the reduction in area from A_2 to A_1; however, in Fig. 1*b* flow occurs in a region where the area varies from A_2 to A_1 in a continuous manner, hence yielding occurs over a spectrum of stresses. The effective lower yield stress will, therefore, be somewhere between those values of load divided by A_1 and A_2 with the actual value being weighted towards the regions where most of the flow occurs as the band advances. This in turn is a sensitive function of Lüders band profile. Work by Hahn[4] indicates that this 'integrated' area lies nearer A_1 than A_2. In addition to the change in area there is a stress concentration due to the 'notch' produced by the inhomogeneous flow. The enhancement of stress in this case will be fairly localized. Both factors discussed here tend to increase the effective value of σ_y; but the magnitude of these effects is variable.

Some idea of the effective yield stress value can be gained from a plot of nominal lower yield stress and flow stress for various strains versus $d^{-\frac{1}{2}}$ used in conjunction with a plot of Lüders strain versus $d^{-\frac{1}{2}}$. It has been shown that in some materials[5,6] the flow stress curves for various strains are parallel and have a smaller slope than the lower yield stress curve as shown schematically in Fig. 2. Also, each grain size represents a certain Lüders strain as exemplified in Fig. 3 for Armco iron[3]. It is interesting to note from Fig. 3 that a small grain size can have an appreciable Lüders extension at −45° C. Picking a value of 10 per cent Lüders strain for illustrative purposes, the value of the grain size with which this strain is associated is found from Fig. 3. A vertical line is then drawn through $d^{-\frac{1}{2}}_{10\%}$ (Fig. 2) until it intersects the 10 per cent flow stress curve as shown by the asterisk. The difference in stress between this point and the lower yield stress curve represents the stress increase which can be ascribed in part to the sources discussed here. A second corrected yield stress point can be obtained in the same manner as that shown for the 10 per cent strain. This allows one to draw a corrected yield stress curve. The correction factor will decrease as $d^{-\frac{1}{2}}$ becomes smaller, because of the decreasing amount of Lüders strain. In the case where there are no grain boundaries—that is, a single crystal—a correction factor will be required if there is some kind of barrier which can adequately substitute for the missing grain boundaries.

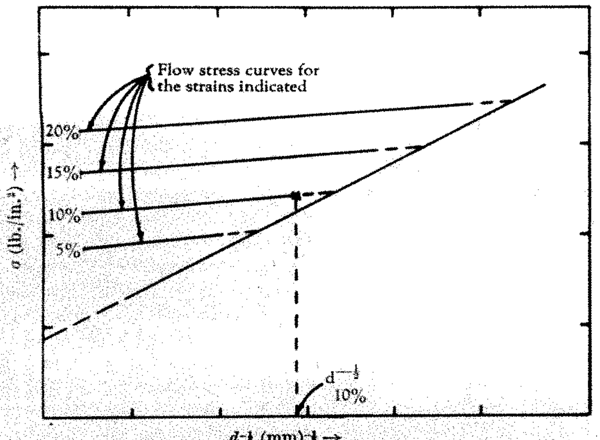


Fig. 2. Schematic illustration of nominal lower yield stress and flow stress at various strains versus grain diameter $(2d)^{-\frac{1}{2}}$

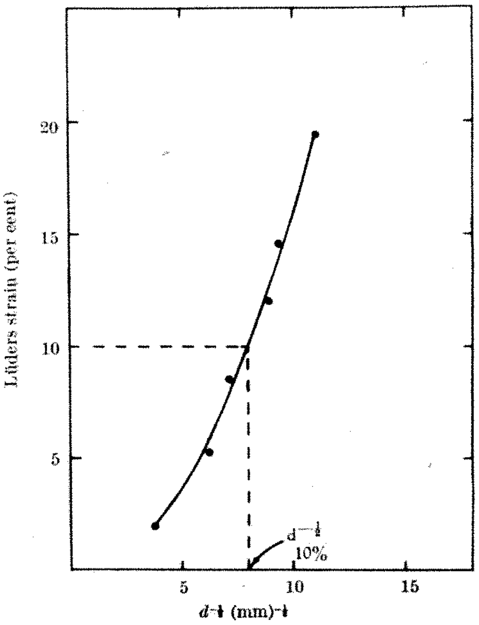

Fig. 3. Lüders strain versus grain size $(2d)^{-\frac{1}{2}}$ for Armco iron at −45° C. Data taken from ref. 3

Some recent results[2,7] support the presence of a discrepancy between nominal lower yield stress and flow stress; but it would be desirable to conduct a series of carefully controlled experiments in order to obtain quantitative values.

It would be anticipated that the suggested correction would be relatively negligible where the Lüders strain is small, but that it could be significant in certain circumstances. In the case of Armco iron at −45° C (Fig. 3), for example, the slope of the σ_y versus $d^{-\frac{1}{2}}$ curve would be increased after making the correction; whereas at room temperature in the same material, where the Lüders strain is much smaller and less grain size dependent[3], the slope would not be affected to nearly the same degree. Thus one's interpretation of the effect of temperature on k_y would necessarily be modified.

The foregoing method allows some idea of the effective lower yield stress to be obtained without resorting to complex analytical techniques. The initial steep slope observed at the completion of yielding may be due, in part, to the removal of the stress concentration factor when the Lüders front disappears. A complicating factor which could be present is that the nominal lower yield stress curve represents the propagation of different numbers of Lüders bands at the different grain sizes. It is known that for a given strain rate the yield stress decreases as the number of bands participating in the lower yield extension increases[8]. For sufficiently precise determinations, however, the stress associated with a fixed number of bands can be determined and used to plot the nominal lower yield stress versus $d^{-\frac{1}{2}}$ curve.

I thank Drs. D. Peacock and B. Harris for their advice and Mr. L. G. Heroux for preparing the illustrations.

CHEMISTRY

A New Continuous Solid-fluid Contacting Technique

A NOVEL technique for continuous countercurrent processes involving contact between particulate solids and fluids has been developed here. This has been carried out on a small-scale apparatus using several different systems from which the essential features of the technique have been verified. The technique is directly applicable to operation on an industrial scale as well as in the laboratory, and has wide potential application in the processing industries.

In its most general sense the technique is a method of contacting a particulate solid phase in countercurrent to a fluid phase with the view of achieving transfer of some soluble component from one phase to the other. The essential novelty of the idea lies in the use of a periodically modulated flow rate of fluid to a cascade of contacting stages by which solid is transferred in a direction countercurrent to the nett flow of fluid. The only necessary property of the system for the technique to be operable is that the dispersion of solid in fluid settles in a reasonably short time. During one part of the operating cycle, fluid flows through a series of fluidized or expanded beds of solid, during another part of the cycle, reversing the direction of fluid flow transfers equal increments of the settled solid beds between adjacent stages in a direction countercurrent to the nett flow of fluid.

Unique advantages of the proposed technique are the reliability and flexibility of operation. Positive control of both solid and fluid flow rates is achieved by direct control of external flows to the contactor, and does not require a fine hydrostatic balance or close tolerances in construction of the equipment. Although maximum flow rates are determined by the actual size of the stages, it is possible with any given unit to obtain a ratio of solid flow rate to fluid flow rate varying from zero to infinity by simple adjustment of the controls.

The main characteristics of the proposed technique may be illustrated by considering the results of one of the laboratory experiments on an ion exchange system.

In this experiment a 0·1 M aqueous solution of cæsium chloride tagged with cæsium-137 was passed at an average flow rate of 33·3 ml./min through a cascade of four 20-mm diameter contacting stages in countercurrent to cationic ion exchange resin ('Zeokarb 225', particle size −14+52 mesh, hydrogen form) moving at an average flow rate of 4·0 ml. of settled resin per minute. The concentration of the solution leaving was found by radiochemical analysis to be 0·004 M in cæsium, giving a cæsium recovery of 96 per cent. A McCabe–Thiele diagram drawn for this system gave the same recovery of cæsium for 3·5 ideal stages. Hence the stage efficiency was about 85 per cent. Details of the modulated flow-cycle are illustrated in the series of sketches, Figs. 1 *a*–*c*, which show the phenomena occurring in the stages corresponding to the instantaneous value of liquid flow rate outlined in Fig. 2. The stages shown in the figures are simplified for clarity and do not represent optimum designs.

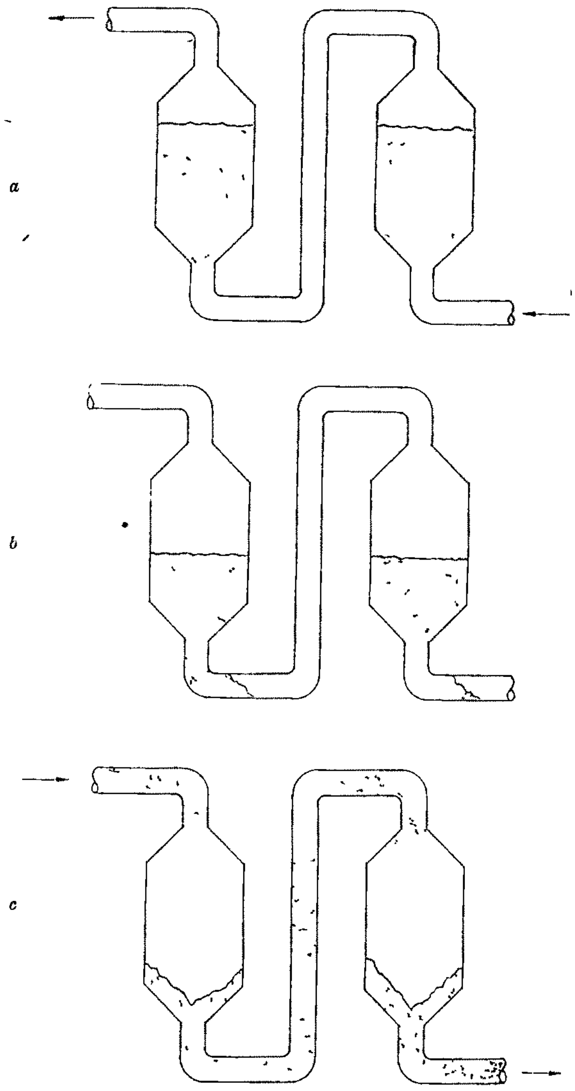

Fig. 1. *a*, Liquid upflow, expanded beds, *b*, no liquid flow, settled beds, *c*, reversed liquid flow, solids transfer

From the brief description given here the technique may be seen to be a hybrid between a series of dense phase moving beds and a multi-stage fluidized bed carried out in specially designed stages. Both the multi-stage fluidized bed and the dense phase moving bed are familiar concepts in the processing industries[1] and require no further description here. There may be an apparent similarity between this concept and the "pulsed sieve tray column" evolved from Swinton and Weiss's original idea in the use of pulsations in the liquid feed[2,3]. However, Swinton and Weiss merely superimposed a high-frequency low-amplitude vibration in the liquid feed to a multi-stage fluidized bed with conventional downcomers in order to promote the ability of the solid to flow. In the proposed technique the fluid feed is controlled in a manner such that the expanded or fluidized beds are settled, and then transferred between stages in the condition known as dense phase flow[1].

The potential industrial applications of this technique are considered to be very wide due to the extreme sim-

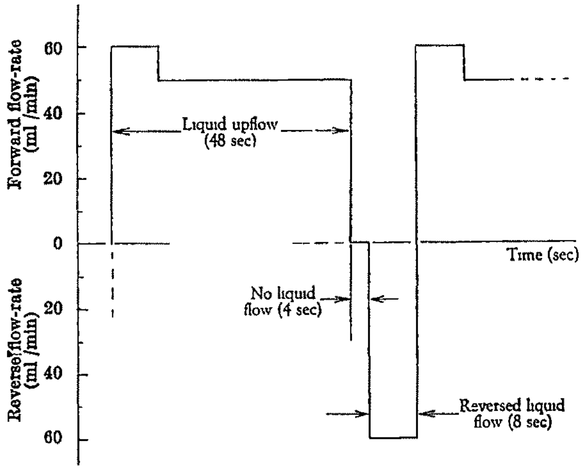

Fig. 2. Flow cycle. Average liquid flow-rate, 33.3 ml./min, average solid flow-rate, 4.0 ml./min.

plicity of its operation and applicability to construction of large-scale equipment.

In the liquid–solid field one could apply this technique to leaching of ores, purification of water, ion exchange recovery of metallic ions and chromatographic separation. For gas–solid systems the scope is more limited, as in most applications this technique would appear to have few economic advantages over a conventional multi-stage fluidized bed, although it would be equally feasible in all cases. In the processing of radioactive or highly corrosive materials this technique would have advantages over alternative methods owing to its simplicity and adaptability for remote operation.

Use of a Digital Computer for Evaluating Ultracentrifuge Data

Fujita and MacCosham[1] have integrated Lamm's differential equation[2] for the ultracentrifuge, and have given analytical solutions which describe the integral and differential forms of the solute boundary for the sedimentation of a two-component system. They suggest that their equations may be of practical value in sedimentation analysis, but until recently the use of these equations for the routine estimation of molecular weights has not been possible because of the time required to perform the necessary calculations. This limitation no longer applies if the arithmetic is carried out by digital computer, and this communication shows how the equations can be used to evaluate apparent molecular weights from centrifuge data that would normally be treated by the method of Archibald[3]. The limitations inherent in the method arise chiefly from the assumption of Fujita and MacCosham that the sedimentation and diffusion coefficients, S and D, of the solute are independent of concentration. This may restrict the usefulness of the method to a particular class of solutes.

Fujita and MacCosham's differential equation for the gradient of concentration below the meniscus reads:

$$\frac{dc}{dr}=\frac{C_0}{r_0}\frac{e^{-\tau}}{\varepsilon}\left\{\left[1-\Phi\left(\frac{z+\tau}{2(\varepsilon\tau)^{\frac{1}{2}}}\right)\right]\left(2+\frac{z+\tau}{\varepsilon}\right)\exp(z/\varepsilon)-\frac{2}{\sqrt{\pi}}\left(\frac{\varepsilon}{\tau}\right)^{\frac{1}{2}}\exp-\left[\frac{(\tau-z)^2}{4\varepsilon\tau}\right]\right\} \qquad (1)$$

where $\tau = 2\omega^2St$ (ω = radial velocity of rotor, t = time), $\varepsilon = 2D/r_0{}^2\omega^2S$ (r_0 = meniscus distance from the centre of rotation), $z = 21 \log r/r_0$ (r = distance from centre of measured dc/dr), c_0 = initial concentration of solute, $\Phi(x)$ = error function defined as $2/\pi^{\frac{1}{2}}\int_0^q \exp(-q^2)dq$.

If values of dc/dr are measured in an experiment at two values of r within the boundary region at a given time of sedimentation and substituted in (1), the constants τ and ε here can be determined by solving the two resulting simultaneous equations. Then from τ and ε the coefficients S and D, and hence[4] the molecular weight, M, can be calculated.

For this purpose the computer is programmed to solve equation (1) by iteration, using a data tape on which are printed the two experimental values of $(dc/dr)_1$ and $(dc/dr)_2$ at r_1 and r_2, respectively, the time of sedimentation, and the various other parameters set out here. To begin the iteration τ is set to an initial value, τ_0, by choosing an arbitrary value of S such that $S > S_{\text{actual}}$. The other constant, ε, is set equal to unity initially, and then the computer calculates from equation (1) the apparent value of dc/dr, say $(dc/dr)_{1\text{app}}$, for $r = r_1$, and for these values of τ and ε. It then compares $(dc/dr)_{1\text{app}}$ with the experimental value $(dc/dr)_1$, and if the two values differ by more than 10^{-5} it decreases ε by successive chosen increments until agreement is reached. In this way a value of ε say ε_1, is obtained for the data at r_1 for τ_0. Next the calculation is repeated, but this time using the experimental value $(dc/dr)_2$ at r_2 to obtain a value ε_2 for $\tau = \tau_0$. The values of ε_1 and ε_2 are now compared, and if $|\varepsilon_1 - \varepsilon_2| > 10^{-4}$, the whole calculation is repeated with successively smaller values of τ until $|\varepsilon_1 - \varepsilon_2| \leqslant 10^4$. When this has been achieved, values of τ and ε, and hence D and S, have been found which satisfy equation (1) for the data at r_1 and r_2 to within the prescribed limits.

The programme has been tested using data obtained from ultracentrifuge experiments on sucrose. This substance was chosen because its molecular weight and diffusion constant[5] are known accurately, and the effect of concentration on S and D is minimal. A Spinco model E analytical ultracentrifuge fitted with an RTIC temperature controlling mechanism set at 20° C was used to examine a solution of 'AnalaR' sucrose (1.39 per cent) in a 30 m/m cell, with a second cell as counter-poise containing water to produce a base line to the schlieren pattern. The rotor speed was 50,740 r.p.m. and photographs were taken at intervals of approximately 16 min.

The mean molecular weight, sedimentation and diffusion coefficients together with their associated errors, are shown in Table 1. The molecular weight obtained was approximately 0.5 per cent lower than the true value (342), but the uncertainty of the estimate, as indicated by the standard error, was ± 2.7 per cent of the mean figure. The estimates of S and D were erratic and higher than the accepted values[5] ($D = 4.57 \times 10^{-6}$ cm sec^{-1}, $S = 0.24 \times 10^{-13}$ sec^{-1}), showing that the main factor controlling the shape of the differential and integral boundaries is the ratio of these two coefficients rather than their absolute values. It must be remembered that in calculating S from τ the value of the time t is an assumed one, and some inaccuracy may be introduced here due to uncertainty in making allowance for the period of acceleration. This in turn affects the calculation of D from the ratio S/D. Further experiments will be required before any comment can be made on the magnitude of the standard errors of these results. The computer programme will be available to others as required, and it is hoped that this will allow a rapid test of the method.

Table 1 Molecular weight, sedimentation (S) and diffusion coefficients (D) of sucrose, determined from pairs of co-ordinates taken from five exposures Allowance was made in the exposure time for the period of acceleration to 50,740 r p m , r_0 = 6 074 cm

				S E ±	9 4	0 13	0 05	0 85

* dn/dr = refractive index gradient × tan θ, where θ = angle of schlieren phase-plate

It is essential in this method of molecular weight assessment to measure co-ordinates with a high degree of precision Thus the frequently used procedure of tracing an enlarged image on to graph paper is insufficiently accurate, and a micrometer method must be used In the present experiment the parameters were measured using a digital scanner ('Oscar', Benson and Lehner, England) which automatically prints the data in a form suitable for immediate insertion into the computer The use of this device greatly reduces the time required for accurate measurement, and in the present case each exposure required only about 1 min for measurement The digital computation took an average of 6 sec on a Ferranti *Atlas* computer

I thank Dr G A Gilbert, Department of Chemistry, for his advice, Mr K A Redish, Department of Mathematical Physics, for help in writing the computer programme and the Agricultural Research Service, U S Department of Agriculture, for a grant under *P L* 480

Asymmetric Synthesis of α-Amino-acids by the Strecker Synthesis

THE non-enzymatic asymmetric synthesis of α-amino-acids has long been of considerable stereochemical interest However, the method of catalytic hydrogenation is the only one appearing in the literature[1-8] In this communication, a new method of asymmetric synthesis of α-amino-acids in solution is described

The method involves (*a*) the reaction of an aldehyde with hydrogen cyanide and D-(–)-α-methylbenzylamine ($[\alpha]_D^{27} = -40\ 6°$ in benzene) in methanol, (*b*) hydrolysis of the resulting amino nitrile to the *N*-(α-methylbenzyl) amino-acid, (*c*) catalytic hydrogenolysis to remove the methylbenzyl group A typical example of the asymmetric synthesis is as follows sodium cyanide, 1 47 g (0 03 mole), and D-(–)-α-methylbenzylamine hydrochloride, 4 73 g (0 03 mole), were dissolved in 5 ml of cold water To this, 20 ml of methanol and 1 0 g of free D-(–)-α-methylbenzylamine were added Then, acetaldehyde, 1 32 g (0 03 mole), was added to the cold methanolic solution The clear solution was kept at room temperature for five days The solvent was evaporated *in vacuo* The residue was dissolved in 50 ml of 1 N hydrochloric acid and the solution was extracted twice with ether To the aqueous solution was added 12 N hydrochloric acid to adjust the normality of the acid to approximately 5 N The solution was then refluxed for 6 h The hydrochloric acid was evaporated *in vacuo* and the residue was dried over sodium hydroxide under reduced pressure The crude *N*-(α-methylbenzyl) alanine hydrochloride was dissolved in 200 ml of 50 per cent alcohol and the *p*H was adjusted to 6 0 with sodium bicarbonate To this solution, 3 5 g of palladium hydroxide catalyst[8] was added Hydrogenolysis was carried out for 10 h to remove the methylbenzyl group The catalyst was filtered and washed with hot water The combined filtrate was evaporated to about one-third volume and acidified with dilute hydrochloric acid to about *p*H 1 The solution was evaporated to dryness and the alanine hydrochloride was extracted from the dry residue with absolute ethanol three times (total 50 ml) The solution was kept at –5° C overnight to precipitate the contaminated salt After filtration, pyridine was added to the alcoholic solution to precipitate crude alanine Yield, 0 71 g $[\alpha]_D^{27} = +10\ 01°$ in 6 N hydrochloric acid c = 2 18, m p 235°–243° dec A single spot was observed following paper chromatography The crude alanine which contains salt was dissolved in 2 5 ml of water, the *p*H was adjusted with pyridine to 5 5–6 0, and 10 ml of absolute ethanol was added A yield of 0 45 g of L-alanine was obtained (17 per cent) $[\alpha]_D^{27} = +13\ 13°$, in 6 N hydrochloric acid, c = 2 32, asymmetric yield, 90 per cent, m p 290° dec Anal calcd for $C_3H_7NO_2$: C, 40 44, H, 7 92, N, 15 72 Found C, 40 53, H, 8 07, N, 15 78

The intermediate *N*-(α-methylbenzyl)alanine was isolated using the reaction conditions here After hydrolysis and evaporation of the hydrochloric acid, the residue was extracted with absolute ethanol Pyridine was added to the solution and the ethanolic solution was kept at 5° C for 2 days to complete the precipitation of *N*-(α-methylbenzyl) alanine A yield of 0 85 g (15 per cent) of material was obtained m p 277° dec , $[\alpha]_D^{27} = -41\ 96°$ in 6 N hydrochloric acid, c = 1 91 The product was purified by sublimation[8] (0 1 mm mercury at 200° C), 0 68 g of pure *N*-(α-methylbenzyl) alanine was obtained m p 281° dec , $[\alpha]_D^{27} = -43\ 9°$ in 6 N hydrochloric acid c = 2 15, anal calcd for $C_{11}H_{15}NO_2$ C, 68 37, H, 7 82, N, 7 25 found C, 68 21, H, 7 81; N, 7 26 Hydrogenolysis of this gave L-alanine, $[\alpha]_D^{27} = +13\ 99°$ (95 per cent optically active)

The mechanism of the asymmetric synthesis has not been clarified However, the synthesis may involve several sterically controlled reactions[9]

The Strecker synthesis of amino-acids has been considered as one of the modes of formation of amino-acids in the primordial Earth[10-12] The asymmetric synthesis described here is therefore interesting in connexion with the formation of optically active amino-acids on the primitive Earth This type of asymmetric synthesis is under further investigation

Molecular Formula and Degree of Unsaturation

A RELATION stated without proof or reference by Soffer[1] deserves to be better known. Ideas more or less equivalent to it seem to be widely known to organic chemists, but workers in related fields may find the result useful when dealing with organic compounds. This communication presents a proof, together with some remarks on interpretation and use (supplementary to Soffer's remarks).

For a start, consider a molecule the molecular (numerical) formula of which is known, and the atoms of which can safely be regarded as covalent with predictable valencies. Thus we can calculate the sum V of the valencies of all the atoms. The number of bonds in the structure must be $\frac{1}{2}V$ because each bond satisfies two valencies.

But if there are N atoms then as few as $N-1$ bonds are sufficient to link them together—one bond would serve to link two atoms, a second bond would allow a third atom to be added, and so on.

If this were fewer than $\frac{1}{2}V$, then each of the extra bonds must link atoms which are already linked either directly or indirectly in the molecule. If indirectly, then such an extra bond completes a ring; if directly, it gives us a double bond (or increases the order of a multiple bond). Always we get what Soffer calls a "cyclic element of structure". (A triple bond is to be counted as two cyclic elements.) Thus the number of these cyclic elements is predicted as the number of 'surplus' bonds

$$\rho \text{ (say)} = \tfrac{1}{2}V - N + 1 \qquad (1)$$

Also 2ρ is the number of added hydrogens required to saturate the molecule (eliminating all bond-duplications and rings) because each pair of hydrogens eliminates one of the 'surplus' bonds.

(1) We see that two molecules have the same ρ-value whenever their molecular formulæ are identical (isomeric); or when the formulæ differ only by multiples of CH_2, NH and/or O, because these combinations contribute zero to $(\frac{1}{2}V - N)$.

(2) Equation (1) may be written

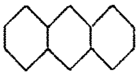
$$\rho = \tfrac{1}{2}\Sigma v n_v - \Sigma n_v + 1$$

where n_v is the number of atoms of valency v, and rearranged to give Soffer's form

$$\rho = 1 + \tfrac{1}{2}\Sigma n_v(v - 2) \qquad (2)$$

(that is, $\rho = 1 + \frac{1}{2}(2n_4 + n_3 - n_1)$ if no higher valencies are present). This gives a quicker calculation if it can be remembered.

(3) Soffer's definition, "in counting the number of cyclic structures in a polycyclic system no cyclic structure is counted if it is made up entirely of elements of other cyclic structures which themselves have been counted", can give ambiguous results in some cases. Thus tetradecahydroanthracene, $C_{14}H_{24}$, gives $\rho = 3$ and has indeed three six-membered rings



but could be counted as having only two rings, the middle one and the 'outside'. In such a case, we must say that ρ predicts the number of bonds that must be cut to eliminate all the cyclic structures. (For formally planar structures it is sufficient to count non-overlapping rings.)

(4) The equation holds if the true structure has the atoms in their predicted covalencies, or if an acceptable model of the structure has this property. Thus aromatic nuclei may be considered as having Kekulé structures as Soffer apparently intends when he cites benzylpenicillin and strychnine. (Alternatively we may arbitrarily call each aromatic (π) electron-pair a 'cyclic structure'.) A benzene ring is a possible explanation of four units of a calculated unsaturation.

Similar considerations apply to the groups $-NO$ and $-NO_2$ (count one cycle each), but substituted ammonium is more difficult to deal with as it appears 'supersaturated' until we calculate again using valency five for the nitrogen.

(5) The equation may be generalized to a set of atoms other than a single complete molecule. By adding equations for M separate molecules we obtain

$$\rho = \tfrac{1}{2}V - N + M \quad \text{or} \quad \rho - M = \tfrac{1}{2}V - N$$

where N, V, ρ are the total number of atoms, valencies and cyclic elements in the M molecules. Here M replaces the 1 of equation (1) (or (2), similarly). On the other hand, we must subtract $\frac{1}{2}$ from the same figure for each valency either not satisfied (as in a free radical), or not satisfied within the set of atoms (such as the monomeric unit of a dimer or polymer, or 'structural units' of coal[2]).

Near Ultra-violet Absorption Spectra of o-, *m*-, and *p*-Fluorophenol Vapour

THE absorption spectra of *o*-, *m*-, and *p*-fluorophenol in vapour phase have been examined with a Hilger E_1 large quartz spectrograph. A number of plates were taken with different cell lengths and at temperatures ranging from 26° C to 60° C, while the temperature of the reservoir containing the substance varied from −15° C to 60° C. The bands in each case appear well defined with the cell of length 70 cm maintained at temperature 26° C. A hydrogen lamp was used as the source of continuum for the ultra-violet region. Ilford special rapid N 40 plates were used to photograph the spectra in about half an hour.

Nearly 300 bands have been photographed in each case. The intense bands are double headed, similar to those observed in the case of phenol. The mean doublet separation in all the three spectra is found to be of the order of 10 cm^{-1}.

o-Fluorophenol. This molecule belongs to symmetry class *Cs* to a first approximation and its absorption spectrum is due to the electronic transition ${}^1A' \leftarrow {}^1A'$. The most intense band at 36,802 cm^{-1} has been chosen as the (0, 0) band, and the entire spectrum analysed in terms of the frequencies 239, 415, 566 and 766 cm^{-1} in the ground state and 291, 506, 718, 945, 1,040 and 1,128 cm^{-1} in the excited state. The ground state frequencies correspond fairly closely to the known Raman frequencies.

m-Fluorophenol. The *meta*-derivative of the molecule can also be taken to belong to the symmetry class C_s and the bands may be attributed to the electronic transition ${}^1A' \leftarrow {}^1A'$ which is an allowed transition. The intense band at 36,620 cm^{-1}, which is observed with still greater intensity at low temperature, is taken to be the (0, 0) band. The entire spectrum is analysed in terms of two ground state frequencies, 427 and 741 cm^{-1}, and six excited state frequencies, 146, 206, 254, 713, 976 and 1,175 cm^{-1}.

p-Fluorophenol. The *para*-derivative belongs to C_{2v} symmetry class approximately, and the observed spectrum involves the electronic transition ${}^1A_1 \leftarrow {}^1B_1$, which is allowed with the transition moment lying in the molecular plane and perpendicular to C–OH bond. The most intense band at 35,132 cm^{-1}, which appears with increased intensity at lower temperatures, has been taken to be the (0, 0) band. The bands have been analysed in terms of three ground state frequencies 251, 466 and 865 cm^{-1}, and seven excited state frequencies, 356, 413, 569, 838, 875, 1,205 and 1,273 cm^{-1}. Satisfactory correspondence of the ground state frequencies has been found with the Raman frequencies of the molecule

A comparison of these spectra with those of phenol and of the corresponding chlorophenols has revealed many interesting features These are under investigation with spectrographs of higher dispersion and resolution. A detailed investigation of these spectra and their analyses will be published shortly

Surface-active Characteristics of Sodium Salts of Anacardic Acids of Varying Unsaturation

CASHEW nut (*Anacardium occidentale* Linn) shell liquid chiefly consists of anacardic acid, an *ortho*-carboxymeta-alkyl phenol. Earlier workers[1–3] have shown that the unsaturated alkyl side-chain in the acid consists of 15 carbon atoms and that the acid is a mixture of saturated and mono-, di-, and tri-olefinic compounds, in proportions that give, on average, about two double bonds per molecule Properties of the sodium salt of the whole anacardic acid have been reported earlier[4–6] However, considerable interest remains in the examination of surface-activity unsaturation relationship in the anacardic acid series The work recorded here is an extension of previous work[5] on whole anacardic acid.

In the present investigation, low-temperature fractionation and chromatographic resolution were used as tools for segregating anacardic acid into fractions Anacardic acid with iodine value 124 7 (as determined by the method of Kale and Kamath[7]) and corresponding to 1 689 double bonds per molecule (on the basis of iodine value of mono-olefinic anacardic acid which is 73 82) was taken as the starting material and was separated into five different fractions *A*, *B*, *C*, *D* and *E* having their iodine values 50 66. 103 00, 125 80, 140 90 and 162 4, respectively

For evaluating comparative surface-active properties, tetrahydro-anacardic acid (THA) with zero iodine value (obtained by hydrogenating anacardic acid in alcoholic medium in presence of platinum catalyst, followed by repeated crystallization from ligroin) and the fractions *B* (nearly mono-unsaturated acid), *D* (nearly di-unsaturated acid) and *E* were chosen

The acids were separately converted into disodium salts[5] and their various surface-active properties were examined

(*a*) Surface tension at 30° C (determined by Du Nouy's tensiometer) of 0 01 per cent solutions of the disodium salts of THA and of the fractions *B*, *D* and *E* were 31 2, 41·0, 43 0 and 45 0 dynes/cm respectively

(*b*) While the interfacial tension of water against *n*-heptane was 39 39 dynes/cm at 30° C (determined by the Stalagmometer method), 0 01, 0 02, 0 05 and 0 10 per cent sodium tetrahydroanacardate in aqueous solution lowered the values to 24 33, 14 33, 8 53 and 4 79 dynes/cm respectively The values for fraction *B* were 28 38, 15 81, 5 18 and < 1 00 dynes/cm and those for fraction *E* were 37 38, 25 85, 12 38, 8 73 dynes/cm respectively

(*c*) The critical micellar concentration of the fractions *B*, *D* and *E* as determined by the conductance-concentration curve method (for details, see previous communications[5]) were 0 032, 0 052 and 0 06 per cent solution

(*d*) Emulsification test (with *n*-heptane) and foam-height experiments were conducted according to procedures already outlined[6] The volumes of emulsified layers after shaking 15 ml of 0 1 per cent solutions of sodium salts of THA and of the different fractions with 5 ml of *n*-heptane for 1 h were 5 4 ml , 5 6 ml , 5 5 ml , and 5 4 ml respectively Foam heights 1 min after the complete discharge of the foregoing solutions were 12 4, 14 8, 14 5 and 15 2 cm respectively.

The results presented here reveal that whereas at low concentration, namely, 0 01 per cent, saturated- or tetrahydroanacardic acid is most surface-active, surface activity of unsaturated products is more manifest at comparatively higher concentrations The rule that critical micellar concentration increases with unsaturation in a homologous series[8] is found valid in the sodium anacardate series

As unsaturation increases, emulsifying and foaming characteristics undergo a slight increase and then a slight fall Neither the saturated nor the most unsaturated anacardate gives the best surface-active and bulk properties, optimum hydrophilic–lipophilic balance lies near the mono- and di-unsaturated anacardate The whole anacardic acid as such is a good surfactant as shown before[5,6], its unsaturation falls more or less in the optimum hydrophilic–lipophilic balance zone

Thermal Decomposition of Benzyl Borate

IN recent years, the mechanism of the thermal decomposition of esters has been thoroughly investigated, and at the present time extensive evidence has been presented to support a *cis* elimination pathway[1] A similar mechanism was also suggested to explain the pyrolysis of borate esters[2–4], however, the recent work of Chapman and Borden[5] has disclosed the carbonium ion nature of this decomposition

In an investigation of the secondary decomposition mechanisms in the pyrolysis of esters, the degradation of the borate of benzyl alcohol was attempted This carbinol is of some interest, since it cannot undergo the normal elimination reaction The experimental method developed by O'Connor and Nace[3] was used in the decomposition A mixture of benzyl alcohol (5 00 g, 0 046 mole) and boric acid (2 85 g, 0 046 mole) was slowly heated to 140° The mixture was then kept at this temperature for 2 h After this time, the temperature of the heating bath was slowly raised to 300°–310° Decomposition was complete after 1 h The crude products were then dissolved in benzene and chromatographed on alumina Elution with benzene–hexane afforded anthracene (0 860 g, 21 per cent), and a yellow gum (2 73 g)

In contrast to the borate, the thermal decomposition of benzyl acetate[6] and benzoate[7,8] has been investigated and the major products of these decompositions are benzaldehyde, toluene, and the corresponding anhydride There is some evidence of a bimolecular decomposition in these esters[8,9] with the formation of benzyl ether as an intermediate Although very little is known about the pyrolysis of these esters, it is evident that the borate and benzoate of this alcohol pyrolyse via different reaction pathways

Polarography of Cadmium Transfusion–Gelatin Mixtures

PROTEIN solutions, generally used as maxima suppressors in polarographic work, are known to cause abnormal decrease in the diffusion current of metal ions due to factors such as adsorption[1,2], viscosity[3] and metal protein interaction[4–6] The effect of increasing concentration of serum albumin on the limiting current of cadmium ion has been systematically investigated by Tanford[4], who explained the marked decrease in the current in view of cadmium-protein complex formation Investigations in this direction have not, so far, been undertaken in the case of gelatin, although the latter has been most widely used as the maximum suppressor To meet this end, transfusion gelatin, a modified product of bone gelatin, with its well-characterized nature (in terms of hydrogen ion equilibria[7] and mol wt [8]) was chosen and the effect of factors like *p*H, metal and protein concentration on the limiting current of cadmium was investigated

Chemically pure samples of cadmium sulphate, potassium chloride, ammonium chloride, ammonia and transfusion gelatin (kindly supplied by the Director, National Chemical Laboratory, Poona) were used to prepare solutions in conductivity water and the metal content determined gravimetrically[9] Ammoniacal as well as Walpole acetate buffers were made from 0 1 M solutions and their *p*H measured by Beckman *p*H meter model *G* Polarographic measurements were carried out with a Fisher electropode in conjunction with a Multiflex galvanometer type MGF_2 in the external circuit, using an H-shaped polarographic cell[4], triply distilled mercury (for D M E) and a water thermostat (Townson and Mercer, Croydon) maintained at 25° ± 0 1° C Capillary characteristics determined by Lingane's method[10] were

$$m^{2/3}t^{1/6} = 1\ 87,\ h = 52 \text{ cm and length of capillary, } l = 15 \text{ cm}$$

Nitrogen gas (purified by passing through alkaline pyrogallol and chromous chloride solution) was used to maintain the inert atmosphere The diffusion currents were measured by extrapolation method The mixtures prepared were (1) containing 0 333 mM Cd^{++}, ammoniacal buffer (*p*H 9 6), potassium chloride (to maintain ionic strength, $\mu = 0\ 15$) and varying concentrations of protein, namely, 0, 0 30, 0 40, 0 60, 0 65, 0 71, 0 75, 1 00, 1 20 and 1 35 per cent, (2) containing 2 5 per cent protein, buffer (*p*H 9 6) potassium chloride ($\mu = 0\ 15$) and different concentrations of Cd^{++} (2 664, 2 331, 1 998, 1 665, 1 332, 0 992, 0 666 and 0 499 mM), (3) containing 1 0 per cent protein, 0 333 mM of Cd^{++}, buffers of different *p*Hs 11 0, 10 0, 8 50, 6 8, 6 35, 5 95, 5 85, 4 50, 4 01, 3 80, 3 65, 3 00 and 2 65 and potassium chloride ($\mu = 0\ 15$) A set similar to (2) was also prepared without protein The reversibility of the waves was checked as described by Kolthoff and Lingane[3] Values of diffusion currents, *id* and *ido*, in presence and absence of the protein are given in Fig 1 (plots of *id*/*ido* versus *p*H, metal or protein concentrations) The limiting value of *id*/*ido* from the three curves (*A*, *B*, *C*) came out to be 0 73

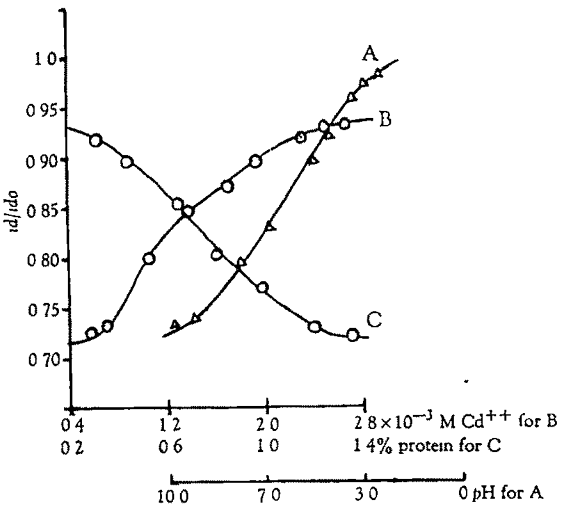

Fig 1 Effects of *p*H, metal ion and protein concentrations on diffusion current depression Curves *A*, *B* and *C* represent respectively the effects of *p*H, metal ion and protein concentrations on diffusion current decrease of cadmium ion at a total ionic strength of 0 15

From Fig 1 it is evident that the ratio *id*/*ido* decreases with increase in *p*H and protein metal ratios and attains a limiting value (not zero), showing thereby that non-specific forces like viscosity and adsorption are not responsible for the considerable decrease in the diffusion current in the case of cadmium Therefore, the metal-protein interaction is the only way to account for these observations Furthermore, the fact that it did not vary exactly as $\sqrt{h}$ shows that the limiting current is not entirely diffusion controlled[11] and a process slower than diffusion is involved in the reduction of cadmium ion bound to transfusion gelatin

The values of V_M calculated at different *p*Hs by the help of Tanford's equation were found to be approximately 2 at *p*H 8 5, where imidazole groups (in addition to carboxyl ones) offer principal sites[8] for metal ion binding Since the value of V_M at *p*H 5 8 is 1, it may be concluded that one cadmium ion is bound to the protein through its imidazole group Similar results have been reported by Tanford[4] and Gurd[12] in the case of serum albumin The value of log *K* calculated from Scatchard's[13] equation comes out to be 3 03 and $-\Delta F$ = 4 118 kcal/mole (at Cd^{++} concentration 0 333 mM)

BIOCHEMISTRY

Role of Deoxyribonuclease in Synthesis of Deoxyribonucleic Acid

ALTHOUGH a considerable amount of work on DNA synthesis has been done in recent years in different laboratories, the exact mechanism of DNA replication in a living cell is not known even to-day. It is also not known whether or not a DNA molecule as a whole, with 10,000 nucleotides, or a part of it or smaller fragments of it, acts as a template for DNA or RNA synthesis.

Based on the observations that concentrations of both DNase activity and DNA are considerably higher in the liver of young rats than normally found in the same tissue of 2–10 months old rats, Devi *et al.*[1,2] suggested a possible role of DNase in synthesis of DNA. The recent reports on the ability of DNase 1 to increase the rate of mitosis in sea-urchin eggs[3] and DNA synthesis in many crude enzyme systems[4,5] led us to investigate the effects of DNase and sonications on the priming efficiency of two-stranded and heat-denatured DNA in DNA-synthesizing systems, previously described by us[6]. In this connexion, it should be mentioned that we[6] have recently found that two-stranded DNA acts more efficiently than heat-denatured DNA as a primer in the system where soluble extract of young or hepatectomized rat liver is used as the source of polymerase; when a soluble extract of old rat liver is used, heat-denatured DNA acts best as a primer. The results of our investigation on the role of DNase in DNA synthesis are reported in this communication.

It is known that if DNA is exposed to the action of different amounts of DNase for the same length of time, it undergoes degradation without denaturation to smaller fragments of various chain lengths having different molecular weights[7,8]. Similarly, when DNA is exposed to sonic vibration it also undergoes degradation without denaturation. In this way, a series of homologous DNA samples was prepared. The samples all differ in molecular weight[7] but retain double-helical structure, so far as can be judged from the shape of their melting point curves. They appear to be identical to the melting point curve of two-stranded, undegraded calf thymus DNA.

The action of DNase on DNA synthesis was examined by adding different amounts of DNase to the assay system before the addition of high-speed supernatant fraction of rat liver. The conditions of the experiment and the method of the preparation of soluble extract are similar to those previously described by us[5,6] and briefly mentioned at the bottom of Tables 1–3. In the second series of experiments, addition of DNase was omitted and all the samples of DNA, obtained after exposing the native, two-stranded DNA to sonication, were added to the assay system to act as primers. The assay method involves the incorporation of ^{14}C-TMP into primer DNA. The results obtained are summarized here.

The results in Table 1 show that addition of DNase to the assay system leads to an increase in the incorporation of ^{14}C-TMP into added DNA. This effect of DNase is observed when either of the two DNA's, two-stranded DNA or heat-denatured DNA, acts as a primer. This effect of DNase can also be noted when the soluble extract, prepared from either young or old rat liver, is used, for example, as the source of polymerase. It is, however, of considerable interest to note that two-stranded DNA, which acts as a poor primer in old rat liver enzyme system, exhibits even greater priming activity than heat-denatured DNA in the same system if the measurements are carried out in the presence of 20 μg of DNase. It can also be seen from our results that when heat-denatured DNA acts as a primer much smaller quantities of DNase are needed. If the concentration of DNase is increased further, the extent of incorporation of ^{14}C-TMP into fragmented DNA falls rapidly.

Table 1. EFFECT OF DNASE ON THE INCORPORATION OF ^{14}C-THYMIDINE INTO TWO-STRANDED AND HEAT-DENATURED DNA, CATALYSED BY SOLUBLE EXTRACTS OF YOUNG AND OLD RAT LIVER

Amount of DNase added (μg)	Soluble extract of 3–4 weeks old rat liver: Two-stranded DNA	Soluble extract of 3–4 weeks old rat liver: Heat-denatured DNA	Soluble extract of 10–12 months old rat liver: Two-stranded DNA	Soluble extract of 10–12 months old rat liver: Heat-denatured DNA
	Counts/min/ml.		Counts/min/ml.	
0	2,272	808	832	1,640
10	2,196	2,288	1,688	3,448
20	4,288	1,556	3,208	2,008
50	448	688	144	280
100	168	364	—	—

Conditions of the experiment: the incubation mixture contained in a volume of 0·4 ml., μm.moles each of *d*ATP, *d*CTP, *d*TTP and 2-^{14}C thymidine (10,000 c.p.m.), 2 mM of mercaptoethanol, Mg-acetate 8·0 μmoles, *tris* acetate 75 μmoles (*p*H 8·5), 350 μg of calf thymus DNA as indicated, Ca^{++} 25 μmoles, 2·5 mg of enzyme protein and 0·1 ml. water; incubation time 1 h at 37° C. DNA polymerase assay was carried out by the disk procedure (ref. 3).

Table 2. EFFECT OF SONIC VIBRATION ON THE PRIMING EFFICIENCY OF TWO-STRANDED DNA IN THE PRESENCE AND ABSENCE OF DNASE IN DNA-SYNTHESIZING SYSTEMS INVOLVING THE USE OF SOLUTE EXTRACT OF YOUNG AND OLD RAT LIVER

Time of sonication (sec)	Soluble extract of young rat liver: Without DNase	Soluble extract of young rat liver: With DNase 20 μg	Soluble extract of old rat liver: Without DNase	Soluble extract of old rat liver: With DNase 20 μg
	counts/min/ml.		counts/min/ml.	
0	2,346	4,163	620	1,994
30	2,674	3,218	790	2,554
60	2,853	5,800	1,200	2,674
120	3,340	2,656	1,888	2,220
180	2,116	1,973	985	720

Conditions of the experiment were the same as given at the bottom of Table 1.

If the priming efficiency of the various homologous samples of DNA, obtained when the latter was exposed to sonic vibration for different lengths of time, are compared it becomes evident that DNA, exposed to sonication for only 2 min, can act best as a primer; in other words, maximum incorporation of ^{14}C-TMP into this DNA occurs. The molecular weight of DNA, exposed to sonication for only 2 min, is approximately one million. These results are illustrated in Table 2 and demonstrate that if DNA is first subjected to the action of sonic vibration and then the incorporation of ^{14}C-TMP into DNA is measured in the presence of DNase, a further increase in the incorporation of carbon-14 is noted. This increase in the incorporation of carbon-14 is observed only if the time of exposure to sonic vibration is less than 2 min and when the measurements are carried out in the presence of only 20 μg of DNase or less. If the concentration of DNase or the time of exposure to sonication is increased, the incorporation of ^{14}C-CMP into fragmented DNA drops rapidly. Such a drop in incorporation of carbon-14 is also observed when DNA is exposed to sonication for more than two minutes.

All this information seems to suggest that degraded DNA with an approximate molecular weight of one million, and having a double-helical structure, can act best as a primer in DNA synthesis. It is conceivable that in a living cell the DNA, possessing a molecular weight of six millions or more, at first undergoes a limited degradation, thus resulting in the release of smaller fragments with appropriate chain-lengths of molecular weight of one million. These act as primers in DNA synthesis thereafter. The assignment of such a role to DNase *in vivo* cannot be ruled out, simply on the ground that influenza virus DNA loses its genetic activity if it is acted on by a small amount of DNase which does not even produce any change in its viscosity[9]. Contrary to this, Veldhinsew *et al.*[10] have recently reported that the transforming principle of T_4 DNA remains unaffected even when it is subjected to the action of DNase, so long as the molecular weight of the fragmented DNA does not drop below 50,000 (5×10^5). When these results are considered together with the findings of Devi *et al.*[1,2], mentioned earlier, regarding the DNA content and DNase activity in the liver of rats of different ages, one is led to conclude that DNase should have some specific role in DNA synthesis. If stepwise breakdown of hydrogen bonds between base pairs of the two polynucleotide chains of DNA and its synthesis occur simultaneously[11,12], it is at least conceivable that such a process becomes feasible and can occur more rapidly if fragmented DNA instead of undegraded DNA acts as a primer. If our efforts succeed in demonstrating the retention of biological activity by such fragmented

Table 3. PRIMING EFFICIENCY OF DNA PRESENT IN RAT LIVER NUCLEI AND CALF THYMUS NUCLEOHISTONE, CATALYSED BY SOLUBLE EXTRACT OF YOUNG OR OLD RAT LIVER

Source of DNA	Soluble extract of young rat liver (3–4 weeks old) counts/min/ml.	Soluble extract of adult rat liver (10–12 months old) counts/min/ml.

Nucleohistone (without heating)	2,475	860
Nucleohistone (after heating at 100° C for 10 min)	750	1,680

Conditions of the experiment were the same as given at the bottom of Table 1, the only difference being that instead of purified DNA either rat liver nuclei or calf thymus nucleohistone was added as a primer.

DNA's, then it will be possible to imagine that in a living cell DNA is first degraded by the action of DNase to proper chain lengths and acts as a primer for DNA or RNA synthesis thereafter.

We have also found that DNA present in rat liver nuclei, prepared from calf thymus in 0·25 M sucrose medium containing 0·004 M Ca^{++}, and nucleohistone, prepared from calf thymus, can also act equally well as a primer in DNA-synthesizing systems, although the extent of ^{14}C-TMP incorporation is much less than that which can be obtained when two-stranded DNA, degraded by sonic vibration, acts as a primer in the presence of DNase, under the best conditions of experiment. It is therefore clear from the results of Table 3 that histone cannot prevent, to any measurable extent, the synthesis of DNA. Bonner *et al.*[13] reported that DNA of pea embryo chromatin, complexed with histone, was inactive in the support of DNA-dependent RNA synthesis. In rat liver nuclei or calf thymus nucleohistone this does not seem to be the case, as DNA in them can act freely and efficiently as a primer in our DNA-synthesizing system. Sarkar and Dounce[14] previously reported that calf thymus nuclei exhibit very high proteolytic activity. It is therefore possible that histone, part of the DNA–histone complex, undergoes rapid hydrolysis, releasing the DNA to act as a template in DNA synthesis.

All the foregoing results clearly indicate that DNase does have a definite role in DNA synthesis.

Heterogeneity of Human Intestinal Alkaline Phosphatase

INVESTIGATORS who have examined the distribution of alkaline phosphatase after starch-gel electrophoresis of extracts of human small intestine have found the main enzyme activity concentrated in a single, rather diffuse zone in the haptoglobin region, with occasionally one or two minor, slow-moving components also present[1-4]. Chromatography on substituted cellulose columns has, however, revealed considerable heterogeneity in the main phosphatase peak of some intestinal preparations[5,6]. In order to resolve this apparent discrepancy between the results with the two techniques, intestinal phosphatase fractions obtained by column chromatography have now been compared directly with those seen on starch gels.

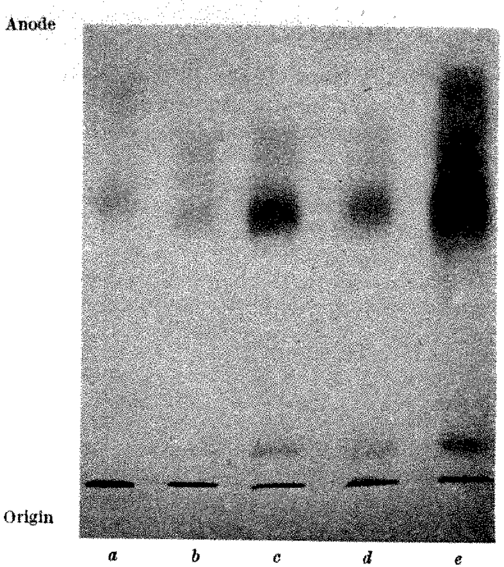

Fig. 1. Alkaline phosphatase zones after starch gel electrophoresis of intestinal extracts: *a*, autolysed for 4 months; *b*, *c*, *d*, butanol extracts of duodenum, jejunum and ileum; *e*, butanol extract of small intestine stored for 4 months

Extracts of specimens of human small intestine obtained within 24 h of death were made by Morton's butanol method[7]. Phosphatase was eluted from columns of DEAE-cellulose by an increasing concentration of chloride ion in *tris* buffer[5]; 3-ml. fractions were collected and

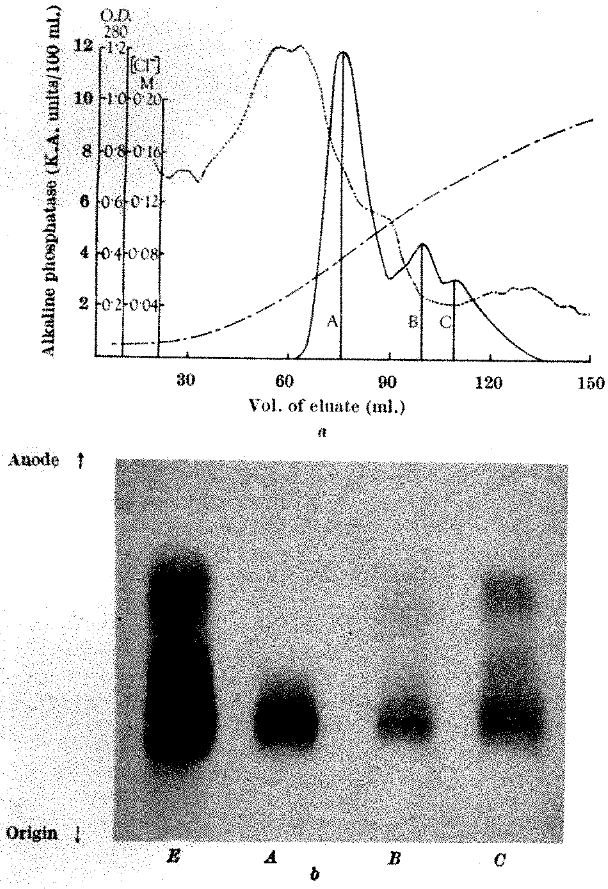

Fig. 3. *a*, DEAE-cellulose chromatogram of butanol extract stored for 4 months at −20° C (key as for Fig. 2*a*); *b*, Starch-gel electrophoresis of column fractions *A*, *B* and *C* and whole extract *E*

alkaline phosphatase activity, optical density at 280 mμ and chloride concentration measured in each. Horizontal starch-gel electrophoresis was carried out in the discontinuous buffer system of Poulik[8] and was continued until the visible junction of the two buffers had moved some 16 cm past the sample slots; the leading edge of the phosphatase zones was then about 10 cm from the origin. Phosphatase bands were located on the gel by the method of Estborn[9].

The single, broad phosphatase band previously found[3] was resolved into at least two components by the extended electrophoretic run (Fig. 1); these components maintained their relative mobilities when re-run on starch gel. In fresh butanol extracts the slower of the two main zones was stronger, the ratio of the relative activities in the slower and faster zones (determined by eluting the enzyme from the gel) varying between 2 : 1 and 4 : 1 in different preparations. Tissues taken from different segments of the intestine all showed these two bands, but no correlation was found between the relative proportions of the bands and the anatomical site of the specimen. When fresh butanol extracts of small intestine were chromatographed, the electrophoretically slower zone was eluted from the column first, the faster zone appearing as a shoulder on the main enzyme peak (Fig. 2). A third active component of intermediate mobility could also be detected eluting with the slower zone.

During storage at −20° C for about 4 months the electrophoretic pattern of the phosphatase in butanol extracts changed, the mobility of the faster zone increasing and the presence of a third zone becoming more apparent (Fig. 1). The chromatographic pattern of the stored extract was similarly more complex (Fig. 3). Prolonged autolysis of an intestinal homogenate (4 months at 4° C) also increased the mobility of the faster zone (Fig. 1), but in this sample the intermediate zone was less apparent.

The several alkaline phosphatase fractions which can be separated by chromatography or electrophoresis may represent structurally different, but functionally similar, enzymes. They may, however, be derived from a single enzyme; different enzyme molecules may remain attached during extraction to other substances, with which they are associated as a result of differences in intracellular localization, or the enzyme molecule may be partly modified after death or during the extraction process. If post-mortem modification of the phosphatase molecule is involved the process might be expected to go to completion during prolonged autolysis, one component vanishing if all the enzyme is degraded. Though there were alterations in electrophoretic mobility of the phosphatase components in the homogenate allowed to autolyse for 4 months, they did not change very strikingly in relative intensity.

When eluted from 'Sephadex *G*–200' with 0·9 per cent saline the phosphatase activity in the tissue extracts appeared as a single, smooth peak with no resolution into separate bands; the different mobilities on starch gel would therefore appear to be due to differences in charge rather than in molecular size.

Gamma-Hydroxybutyrate, a Normal Brain Metabolite

THE finding that γ-aminobutyric acid undergoes an omega transamination to succinic semialdehyde in brain[1] and the subsequent description of a specific dehydrogenase for succinic semialdehyde[2,3] indicated a complete pathway parallel to the Krebs cycle in the brain, which by-passed α-ketoglutarate dehydrogenase—a slow step in the cycle[4]. It was reported in the initial investigation, which demonstrated succinic semialdehyde as an intermediate, that this compound could also effect the oxidation of reduced DPN in brain homogenates, or in the presence of crystalline lactic dehydrogenase. The most likely product of this reaction would be γ-hydroxybutyric acid (1).

$$\text{succinic semialdehyde} + \text{DPNH} \rightleftharpoons \gamma\text{-hydroxybutyrate} + \text{DPN} \quad (1)$$

We have found this new intermediate in extracts of brain tissue of rat, pigeon and man. Brain tissue was ground with 5 per cent trichloroacetic acid and extracted exhaustively with ether. The ether extract was saponified with 1 normal alkali to hydrolyse esters, anhydrides, and lactones. It was then acidified to 2 N in hydrochloric acid and heated to 100° overnight to reform lactones. The lactones were extracted three times with two volumes of ether and the concentrated ether extract was neutralized carefully to prevent saponification and treated with hydroxylamine in dilute alkali[5] to form the hydroxamic acids of the lactones. After the addition of five volumes of methanol to precipitate inorganic salts, the clear methanolic solution of hydroxyamic acids was subjected to ascending paper chromatography in several solvents. The spots were brought out with a spray of ferric chloride. A single major spot was found which corresponded to standard γ-hydroxybutyrohydroxamic acid. Mixtures of unknown with standards gave homogeneous spots. Table 1

Table 1. APPROXIMATE R_F VALUES OF HYDROXAMIC ACIDS CHROMATOGRAPHED

	Acetyl radical of hydroxamate				
Solvent system	Brain extract	γ-OH-butyryl	γ-OH-valeryl	Acetyl	Carbamyl
Butanol, water saturated	0·45	0·45	0·60	0·52	0·19
Phenol, water saturated	0·65	0·65	—	0·68	—
Isobutyric acid, water saturated	0·50	0·50	—	0·55	0·52
Butanol/isopentanol/formic acid/water, 2:2:1:3	0·32	0·32	—	0·40	0·21
Butanol/formic acid/water, 3:1:3	0·40	0·40	0·55	0·50	0·32

gives R_F values of the unknown and standards in various solvents.

The amount of γ-hydroxybutyrate in brain tissue was estimated by comparing the recovery of standard material carried through the same procedures. Rat brain is approximately 1–2 millimolar in γ-hydroxybutyrate and a human brain (no central nervous system disease) taken 3 h *post mortem* was 0·3 millimolar.

The successful use of the sodium salt of γ-hydroxybutyrate in anæsthesia has been reported by Laborit *et al.*[6]. We have confirmed this effect in mice and rats (500 mg/kg IV) and humans (100 mg/kg IV). In all species sleep begins within 15 min and lasts for about 90–120 min. Preliminary tissue investigations in rats show that the sleep period corresponds to an increment of γ-hydroxybutyrate in brain of about 2 millimoles/kg and lasts as long as this level is exceeded. This corresponds to an initial blood-level of about 3 millimolar. Preliminary data on human beings show sleep to occur while the blood-level exceeds 1 millimolar.

The significance of these findings that a normal brain intermediate in relatively small doses can produce sleep is being investigated.

Lipase Formation by Micro-organisms grown on Hydrocarbons

WE have been investigating the utilization of hydrocarbons by micro-organisms, and have already described formation of amino-acids from kerosene by a fermentation process[1]. On the other hand, it is reported[2] that some authors have been examining the production by micro-organisms of feed supplements, fatty acids and other oxidation products from hydrocarbons. Recently, we investigated whether some enzymes are formed by micro-organisms grown on hydrocarbons as a sole carbon source, and have found that extracellular lipase is formed by 5 strains out of 26 micro-organisms tested.

Cultures were grown in the basal medium containing 2·5 per cent kerosene, 0·2 per cent urea (or 0·3 per cent NH_4NO_3) and mineral salts ($MgSO_4 \cdot 7H_2O$ 0·1 per cent; K_2HPO_4 0·1 per cent; Na_2HPO_4 $12H_2O$ 0·05 per cent; KH_2PO_4 0·05 per cent; $FeSO_4$ 0·002 per cent, $MnSO_4$ 0·001 per cent), at 26·5° C on the reciprocal shaker. Though the amounts of lipase formed by those strains are small (Table 1), it seems that fungi which utilize hydrocarbons all show lipase. Lipase activity in the cultured broth was determined by Nord's method modified according to K. Yamada and Y. Ota[3]. One unit is the amount of enzyme which liberates 1 μequiv. acid/min.

Table 1. LIPASE-FORMING STRAINS AND UNITS OF LIPASE FORMED

Strains	Period of cultivation (days)	Nitrogen source	Lipase activity (unit/ml.)
*S*169*M*1 (mould-like)	7	urea	0·4
*S*190*M*3 (mould-like)	7	urea	0·35
*S*192*Y*1 (yeast-like)	2	NH_4NO_3	0·6
*S*200*M*1 (mould)	3	NH_4NO_3	0·3
*S*209*M*1 (mould)	7	urea	0·85

Table 2. EFFECTS OF 'TWEEN-20' AND OLIVE OIL ON LIPASE FORMATION BY *S*192*Y*1 STRAIN

Medium	Lipase activity (unit/ml.)		Period of cultivation	
			2 days	3 days
Basal			0·55	0·4
Basal	'Tween-20'	0·005 per cent	0·95	0·4
Basal	'Tween-20'	0·05 per cent	0·4	0·25
Basal	Olive oil	0·05 per cent	0·3	0·05

Effects of 'Tween-20' and olive oil on formation of lipase by *S*192*Y*1 strain were tested. As shown in Table 2, formation of lipase seems to be slightly stimulated by adding 0·005 per cent 'Tween-20' to the basal medium, while it is prevented when 0·05 per cent of 'Tween-20' or olive oil is added.

Identification of those lipase-forming strains are yet to be made.

Inhibition of Pyruvate Metabolism in Mitochondrial Suspensions by Cobalt

IN a recent publication, Strickland and Goucher[1] claim that, in brief polarographic experiments, cobalt does not inhibit the oxidation by mitochondrial preparations from rat liver of keto-glutarate, β-hydroxybutyrate or pyruvate. On the basis of these findings, the authors suggest that our observations[2] on the particular sensitivity of keto-acid oxidation to inhibition by cobalt may have been artefacts caused by prolonged incubation of the mitochondria in the absence of a phosphate acceptor.

We have confirmed that in the medium used by Strickland and Goucher[1], and in a modification of this (medium II, Table 1), even relatively high concentrations of cobalt produce no significant inhibition of pyruvate oxidation by isolated mitochondria during the first 20 min of incubation in conventional manometric experiments. Strickland and Goucher's[1] incubation medium, however, differs from that used by us not only in the presence of ADP, but also in the contents of inorganic ions, particularly orthophosphate. In our previous papers[2,3] it was emphasized that in studies of this type it is essential to control the phosphate content of the medium, since the latter limits the concentration of free, ionic cobalt that can be maintained in solution. It seems that the failure of Strickland and Goucher[1] to observe the inhibitory action of cobalt on pyruvate oxidation was due to the high (20 mM) concentration of orthophosphate in their medium. Thus, as shown by the data of Table 1, the inhibition of pyruvate metabolism is immediately apparent when the phosphate content is reduced from 20 mM (media I and II) to 8 mM (medium III). In the experiments at the lower phosphate concentration, the buffering capacity of the medium was maintained by the addition of 10 mM *tris*, *p*H 7·4. This prevented the fall-off in oxidation rate that occurred in the presence of 8 mM phosphate as the only buffer, but did not affect the inhibitory action of the cation. Under these conditions, the inhibition produced

Table 1 ACTION OF COBALT ON PYRUVATE OXIDATION BY MITOCHONDRIA FROM RAT LIVER IN DIFFERENT MEDIA

Cobalt concentration (μg/ml)	Incubation medium					
	I (ref 1)	II (Medium I with ADP replaced by 2 mM ATP, and without cytochrome *c*)			III (Medium II with the phosphate content decreased to 8 mM, and the addition of 10 mM *tris*)	IV (ref 2)
	Rate of oxygen consumption (μl /h)					
0	118	162 (162)	135 (135)	111 (77)	145 (145)	134
6			141 (119)			
10		182 (182)		123 (99)	128 (105)	85
15			138 (93)			
30	105	156 (145)	122 (87)	92 (68)	92 (60)	63
60		145 (110)		87 (60)	67 (43)	47
90			109 (63)			

Mitochondria were isolated in 0 25 M sucrose[4], washed and resuspended in 0 25 M sucrose at a density of 3 mg mitochondrial nitrogen/ml[2] Each Warburg flask contained the mitochondrial suspension (0 4 ml) and other components of the experimental system in a total volume of 2 0 ml The flasks were equilibrated for 10 min at 37° before the initial readings The values in each vertical column of the table were obtained with the same preparation of mitochondria, and are calculated from readings taken over the first 20 min of incubation Rates of oxygen consumption after 60 min are given in parenthesis

at a given concentration of cobalt was similar to that observed in our original medium (medium IV, Table 1)

In all media listed in Table 1, the presence of either ADP or ATP was essential for oxidative activity by the mitochondria, but neither the rates of pyruvate metabolism in the absence of cobalt nor the inhibition produced by the cation in media III and IV were affected by replacement of the diphosphate by the triphosphate Cytochrome *c* was unessential, and was omitted from the modification (medium II) of Strickland and Goucher's[1] medium

In the presence of 20 mM phosphate (media I and II) the low concentrations of cobalt (6–10 μg/ml) consistently gave slight stimulation of oxygen uptake, and even at concentrations of 60 μg/ml little inhibition of pyruvate metabolism was obtained until after about 20 min incubation, that is, after termination of the measurements described by Strickland and Goucher[1] Both these observations indicate that in these media the concentration of available cobalt is considerably less than that added Thus, as previously reported[2], stimulation of mitochondrial pyruvate oxidation occurs at sub-inhibitory concentrations of cobalt (less than 1 μg/ml) The delay in the onset of inhibition at the higher levels is possibly related to the reduced rate of cobalt uptake by the mitochondria that must occur if the concentration of free cation is limited by the solubility of a phosphate (complex). It seems unlikely that this delay reflects mitochondrial damage, since, in the absence of cobalt, the rate of oxygen consumption usually remained constant for at least 60 min (Table 1, media II and III)

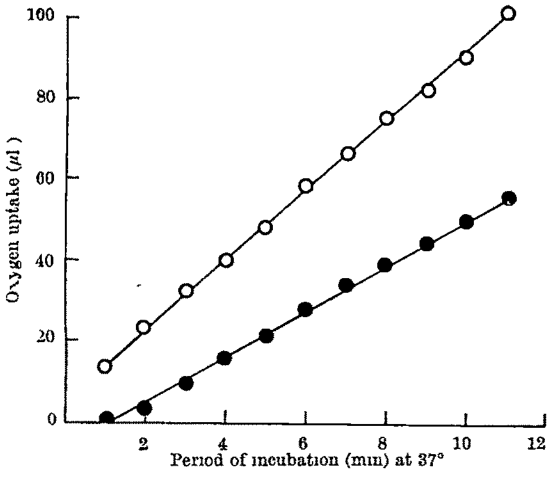

Fig 1 Inhibition of mitochondrial pyruvate oxidation by cobalt. Experimental conditions as described in the text O, control, ●, 1 μg atom Co^{2+}/ml

Certainly the criticism that the observed sensitivity of keto acid oxidation to cobalt under the appropriate conditions is an artefact due to the prolonged incubation, is invalid, since inhibition by the cation can be observed within very short periods To demonstrate this manometrically, two flasks of similar constants, both prewarmed to 37°, were used for each experiment Each contained the components of medium IV in the main compartment and 5 N sodium hydroxide (0 2 ml) in the centre well At zero time, the mitochondrial suspension (3 0 mg N/ml , 0 5 ml) was added to one flask, and 0 25 M sucrose (0 5 ml) to the other After the introduction of the filter paper strips into the centre wells, the flasks were attached to the manometers and inserted into the water bath within 40 sec, the manometer taps being closed after a further 60 sec Readings of the two manometers were taken 2 min from zero time, and at 1-min intervals for 11 min thereafter

Oxygen consumption by the mitochondria was then derived from the difference between the volume changes in the experimental and control systems The rates of oxygen uptake determined by this method were linear and reproducible Control mitochondrial suspensions consumed 8 6 μl oxygen/min This was reduced to 5 5 μl oxygen/min in the presence of 1 μ-atom cobalt/ml (Fig 1) Although the inhibition (36 per cent) observed under these conditions is less than that (53 per cent) produced by the same Co^{2+} concentration over a 20-min period (Table 1, medium IV) the results (Fig 1) leave little doubt that, provided adequate levels of free cation are maintained in solution, inhibition of keto acid oxidation by cobalt occurs at times when degenerative changes in mitochondrial organization and metabolism appear improbable

Utilization of Alpha-Ketoglutarate by Red Blood Cells for Glutathione Synthesis

INVESTIGATIONS in this laboratory have indicated that glutamic-oxaloacetic transaminase activity is increased in young red blood cells Subsequent ageing is associated with a marked decrease in activity[1-3] In an attempt to provide some understanding of the possible physiological role of this enzyme in red cells, we were led to an examination of the metabolism of glutathione Sufficient information has already become available to indicate that erythrocytes possess the enzymatic machinery for synthesizing glutathione[4-6] The relatively rapid half-turnover time of glutathione, 65 and 96 h respectively in rat and human red cells[4,7], suggests that this mechanism plays some part in their metabolic economy In addition, it indicates that adequate supplies of substrate amino-acids are available to the erythrocyte In view of the relative impermeability of red cells to glutamic acid[8] there is some doubt as to the exact mechanism by which supplies of this amino-acid are made available to the red cell under physiological conditions Consideration was therefore given to the possibility that glutamic acid might be supplied through transamination of another metabolic intermediate after its entry into the erythrocyte This communication gives data indicating that α-ketoglutarate, the most obvious possibility, can be incorporated into glutathione *in vitro* by human red cells

Assay conditions for this investigation were identical to those used with rat erythrocytes[6] except for the inclusion of amino- or keto-acid labelled with carbon-14 Glutamic acid, cysteine and glycine were present at a final concentration of 0 03 M with incubation under nitrogen for 3 h at 37° C in a Dubnoff metabolic shaker The adequacy of these conditions for the promotion of glutathione synthesis[6] was confirmed, but no attempt was made to determine whether they were also optimal for human erythrocytes When α-ketoglutarate was used, it was substituted for glutamic acid at the same final concentration.

At the end of the incubation period, the red cells were washed three times with Krebs-phosphate buffer and hæmolysed in 10 ml of distilled water After the addition of 20 mg of carrier, glutathione was isolated by precipitation as the copper mercaptide[9] followed by reduction with hydrogen sulphide[4] The resultant solution was analysed for glutathione[10] and a representative portion was dried on stainless steel planchets Counting was done in a Nuclear Chicago gas flow counter with suitable corrections for self-absorption. Control experiments indicated the absence of significant non-specific radioactivity in the isolated material When estimates of red cell uptake of substrate amino- or keto-acids were desired, washings were carried out with incubation mixture devoid of radioactivity. After hæmolysis, a small portion of the hæmolysate was plated and counted directly in addition to the usual estimate of radioactivity in the isolated glutathione

Table 1. UPTAKE OF LABELLED AMINO- OR KETO-ACIDS BY RED CELLS

	Final conc in media (μM/100 ml)	Final conc in red blood cells (μM/100 ml)	
		Exp 1	Exp 2
Glycine-^{14}C	3,000	485	523
Glutamic acid-^{14}C	3,000	39	33
Alpha-ketoglutarate-^{14}C	3,000	305	213

The uptake of glutamic acid, glycine and α-ketoglutarate by erythrocytes after 3 h of incubation is presented in Table 1 The results demonstrate the relative impermeability of red cells to glutamic acid despite the high concentrations in the surrounding medium

Glutathione synthesis was estimated as the amount of incorporation of radioactive amino-acid into the isolated glutathione Quantitation was based on the specific activity of the added ^{14}C-amino- or keto-acid The results of three typical experiments comparing incorporation of each of these substrates are presented in Table 2 together with the mean values from a larger series of separate studies with each acid Although the results were somewhat variable in individual experiments, the mean α-ketoglutarate incorporation was approximately 70 per cent of that for glutamic acid The results for glycine indicate that much greater amounts of this amino-acid are incorporated This discrepancy is no doubt due to the demonstrated differences in permeability of the red cell to each of these amino-acids In all cases, synthesis was estimated from the specific activity of the amino-acid in the medium No attempt was made to correct for dilution by endogenous material While red cell uptake of glycine was sufficient to justify disregarding the negligible dilution by unlabelled amino-acid, this was apparently not true for glutamic acid In the absence of appropriate analysis, no adequate estimate of the effect of endogenous glutamate on the final specific activity appears possible However, an absolute minimum of a two-fold dilution must be involved since the uptake of labelled glutamic acid by the red cell is in the range of endogenous levels of this dicarboxylic acid reported by several investigators[11,12] The decreased incorporation of α-ketoglutarate can be explained in a similar manner Although this keto-acid apparently enters the human red cell much more easily than glutamate, since it appears in the isolated glutathione it is probably converted to glutamic acid by transamination The rate and amount of this conversion are unknown Unless transamination is extremely rapid and complete, the labelled glutamate so formed would also be extensively diluted by endogenous amino-acid

Table 2. INCORPORATION OF AMINO- OR KETO-ACIDS INTO GLUTATHIONE BY RED BLOOD CELLS *in vitro*

Exp No	Glycine-^{14}C	Glutamic-^{14}C	α-Ketoglutarate-^{14}C
		(μmoles 100 ml red cells)	
1	67 0	14 0	17 0

3	60 6	12 7	5 4
Mean	69 7 (16)*	16 0 (9)	10 8 (10)
range	(39–95)	(7 7–23 5)	(5 4–21 3)

* No of experiments

The present results provide experimental evidence of the erythrocyte's ability to utilize α-ketoglutarate in the synthesis of glutathione. The amount of incorporation appears to be consistent with recent results on red cell utilization of α-ketoglutarate[13] Additional study will be required to determine whether this pathway represents the normal physiological mechanism involved in glutathione synthesis Full appreciation of its physiological significance will depend, to a large extent, on the degree to which glutathione is itself further implicated in the metabolic economy of the red cell

Bound Carnitine in Bovine Brain

RECENT evidence for the presence of carnitine in phospholipids of yolk sac has been given by Mehlman and Wolf[1] Accordingly, it was proposed by these authors that phosphatidyl carnitine could represent a bound form of carnitine in avian tissue In contrast to the results of Strack *et al*[2] and Hosein and Proulx[3], their investigations failed to show the presence of any bound carnitine in the mammalian species In this latter case, analyses were performed in the dialysable material obtained from trichloroacetic (TCA) extracts no study was made on the TCA precipitates nor on the non-dialysable residues It is quite conceivable that carnitine could have been present, in the fractions not investigated, either bound to or as a component of phospholipid

In the work recorded here, evidence was sought for the presence of carnitine in the phospholipids of bovine brain The brains were first homogenized in cold 50 per cent aqueous acetone to extract the free carnitine After filtration, the residue was extracted for phospholipids according to a specific method by Erickson and Lands[4] This material, dissolved in a minimal amount of chloroform, was washed several times with water The chloroform was then evaporated under reduced pressure and the phospholipids were hydrolysed in 6 N methanolic hydrochloride[1] After removal of fat with ether, the aqueous phase was decolorized with 'Norit-A' A portion of the final solution, adjusted to *p*H 8 5, was treated with 5 per cent methanolic reineckate to precipitate choline Following filtration, the mother liquor was adjusted to *p*H 1–1 5 to precipitate carnitine according to a method by Bregoff *et al*[5] The reineckate precipitates, dissolved in acetone, were decomposed by using accepted methods[3,5,6] and the final solutions were brought to dryness under reduced pressure at 60° C Inorganic salts were removed by repeated methanolic extraction The material precipitated with alkaline reineckate proved to be a mixture of at least two substances with melting points of 192°–196° C and 243°–250° C Chloroaurate treatment[7] yielded two derivatives which melted at 152°–154° C and 257°–263° C In certain instances material with a melting point of 228°–232° C was also obtained which could not be further purified by washing with 1 per cent hydrochloric acid or by crystallization from ethanol The materials precipitated with acid reineckate had melting points of 143° C and 190°–194° C the chloroaurate derivative of these substances melted at 152°–154° C Pure carnitine, carnitine hydrochloride, and carnitine chloroaurate melt at 196°, 142° and 152° C, respectively Pure choline and choline chloroaurate melt at 247° C and 260°–263° C, respectively (Choline chloroaurate crystallized from acid ethanol melts at 230° C)

Further evidence for the presence of carnitine was also obtained from paper chromatography A portion of the hydrolysate was concentrated to near dryness, extracted with methanol to remove salts and the final solution was subjected to chromatography in the butanol/acetic acid/water (4 1·1) system[8] Two components were detected with iodine vapour, which corresponded to carnitine (R_F 0 22) and choline (R_F 0 40)

From these results it would appear that there is some bound carnitine in association with phospholipid fractions of bovine brain In support of this is the fact that some carnitine remains in the phospholipids even after acetone and water extractions Since carnitine resembles choline in chemical structure, it is not unlikely that this former substance is a constituent of phospholipid as was suggested by Mehlman and Wolf[1]

Investigations are now under way to estimate quantitatively the amount of carnitine in phospholipids of brain and to see if phosphatidyl carnitine could not account for at least part of the bound carnitine

Selenium Content of Fresh Eggs from Normal and Dystrophic Chickens

THE biological role of selenium is as yet unknown, but the evidence accumulating from many investigations[1–13] suggests that this element is necessary in trace amounts for normal structure and function of muscle and other tissues In our investigations on the possible relation between selenium content of tissues and muscular dystrophy occurring as a hereditary disease in chickens, it seemed appropriate to determine the amounts of selenium in eggs from normal and dystrophic birds We thank Prof W Landauer of the University of Connecticut at Storrs for his collaboration

After the eggs had been weighed, albumen and yolk separated and freeze-dried, the selenium was determined by the methods previously reported[14,15]

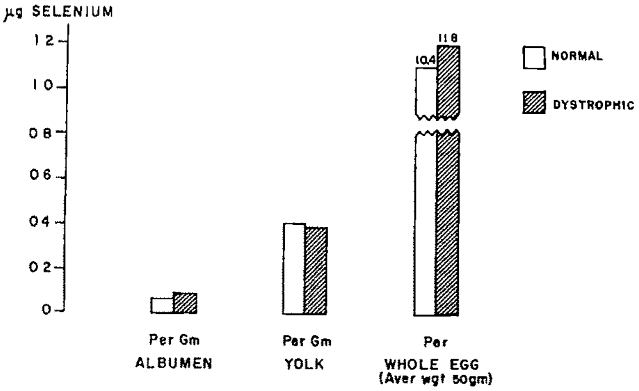

Fig 1 Selenium content of fresh eggs Distribution between yolk and albumen

The results of our investigations are shown in Fig 1 The open columns represent the arithmetic mean of micrograms of selenium per gram of fresh albumen, yoke and whole egg from normal chickens, and the striped bars show the mean values from dystrophic chickens

There was no difference in the selenium content between the eggs from the normal and dystrophic birds , each contained about 11 micrograms of selenium. However, notable and interesting differences in the distribution of the selenium within the egg were found The yolk represents only about a third of the weight of the whole egg, but it contained most of the selenium Similar results were found in all the eggs which were analysed

The presence of appreciable amounts of selenium in the egg, and especially in the yolk, may point to a necessity for selenium in the early development of the embryo Investigations to test this hypothesis are in progress

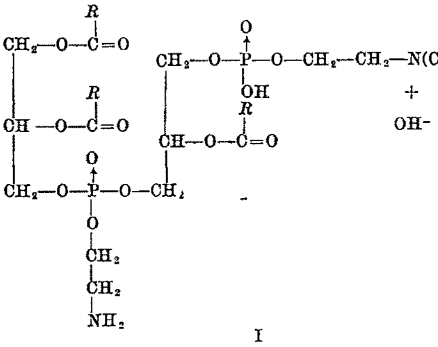
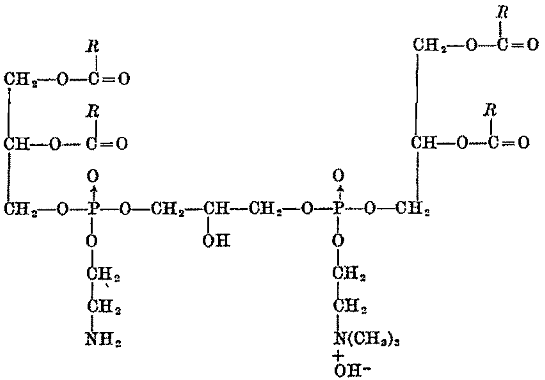
Structure of 'Complex' Phospholipids

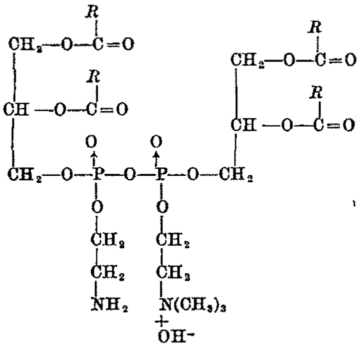
RECENTLY, Collins has described the presence of 'complex' phospholipids in animal tissues[1,2] These compounds are shown to be very sensitive towards silicic acid and other mild hydrolytic reagents This characteristic is believed to be the reason why other workers failed to detect the 'complex' phospholipid fraction, since chromatography over silicic acid is universally utilized in the study of phospholipids. Collins defines the complex phospholipids as having a phosphate triester group and structures such as I and II are suggested; that is, the free hydroxy group on the phosphorus of a 'normal' phosphatidyl-choline, -ethanolamine or -serine is esterified with a glycerol moiety. The hydrolysis of these phosphate triesters by chromatography over silicic acid would give rise to 'normal' phosphatidyl-choline, -ethanolamine or -serine and the corresponding lyso derivatives; compounds which are identical to those which are actually obtained.



I



II



III

For two reasons the evidence described by Collins[1] is, in my opinion, more compatible with a pyrophosphate (acid anhydride) linkage in the molecule, as shown by structure III. First, phosphate triesters are, generally speaking, not unstable compounds[3,4]; pyrophosphates, on the other hand, are easily hydrolysed under moderate conditions[3,5]. Secondly, Collins[1] states that 39 per cent of the rat liver phospholipids consists of complex phospholipids. Hanahan, Dittmer and Warashina[6], who used silicic acid chromatography, found, however, only traces of lysolecithins in rat liver phospholipids. If the complex phospholipids on degradation over silicic acid were to produce lysolecithin this last quantity would be expected to be higher. Hydrolysis of a pyrophosphate structure will liberate only phosphatidyl-choline, -ethanolamine or -serine. The pyrophosphate bond has been shown to exist in proteins[7], and is present in numerous other natural substances (coenzymes). It should also be mentioned that a pyrophosphate structure was originally suggested by Fleury[8] for 'glycerophosphatogen', a substance formed on mild alkaline hydrolysis of lecithin. A rigorous proof of the existence of a pyrophosphate bond in these 'complex' phospholipids could be obtained by enzymatic methods such as those used by Perlmann[7].

PHYSIOLOGY

Analysis of *A* and *B* Wave Interaction in the Rabbit Retina

WORKING with modified versions of Ames's[1,2] technique for maintaining a functioning but isolated rabbit retina, we have presented evidence which strongly supports the hypothesis that the prominent negative wave exhibited by this preparation is equivalent to the *A* wave of the ordinary electroretinogram[3]. In addition, we have been able to analyse this response into photopic and scotopic functions which probably correspond to the A_1 and A_2 waves identified by Heck and Rendahl[4] and others using intact animals. On occasion, the isolated retinal preparation will exhibit what appear to be both the *A* and *B* waves. (The conditions under which the *B* wave occurs are now under investigation. However, at this time we do not have enough results to offer in the form of a communication. Furthermore, at present we must rely on the spurious occurrence of the potential and this accounts for the embarrassing 60-cycle artefact.)

This communication presents results gathered on a preparation which did show both potentials when illuminated by a single 10 micro-second flash of white light. By means of a strychnine technique (unpublished data), it is possible to disassociate in time the apparent peaking of the two components involved in the *A* wave. When these components are sufficiently separated it is possible to observe the emergence of the positive potential out of each negative trough. Fig. 1 shows the effect on the described preparation of increasing the illumination. It will be noticed that at the lowest illumination-level only the A_2 or scotopic function is observable, followed by a positive *B* wave. As the intensity increases, the magnitude of the A_2 wave increases and the A_1 wave appears. Further increases in intensity bring about the emergence of a positive potential occurring later than the A_1 wave but prior to the occurrence of the A_2 wave. The last two pictures in the series show a notch in the *B* wave which corresponds in time to the A_2 wave.

It should also be noted from the results in Fig. 1 that as the A_1 wave becomes more effective in producing a positive potential the general shape or envelope of the *B* wave changes. The appearance of the two positive waves is consistent with the observations of Motokawa and Mita[5], Adrian[6] and Henkes[7], which demonstrated that the *B* wave is composed of photopic and scotopic processes. Another thing is immediately apparent: the time of the peak value of the A_2 wave appears to decrease with increases in illumination. However, a reasonably simple analysis shows that this is, more than likely, the result of differential amplitude variation between the two components. Furthermore, the slope or

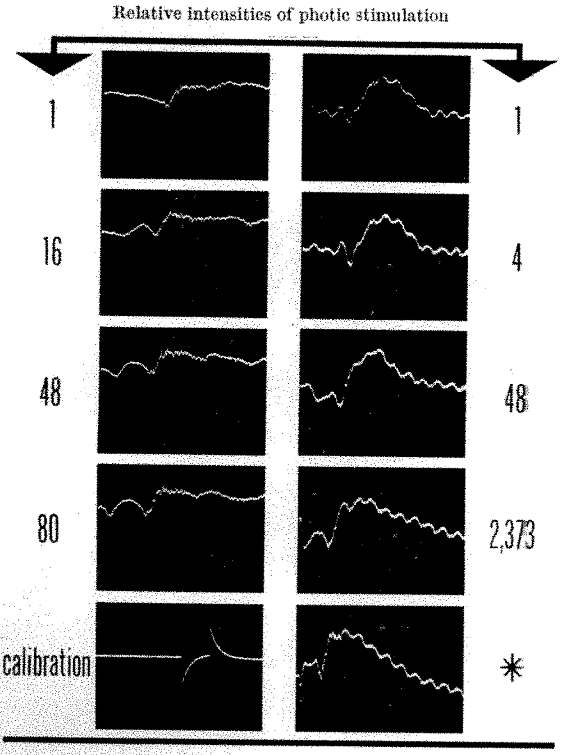

Fig. 1. Effect of increasing the intensity of illumination on the initial negative waves and the emergence of the positive potentials. The results in the left column were obtained by exposing approximately 11 per cent of the centralmost portion of the retina, and the results in the right-hand column were obtained by virtually complete exposure of the retina to photic stimulation. The relative intensities are shown in the figure. Calibration is 100/μV/cm, negative downward. The sweep speed is 10 msec/cm for the data in the left column and 20 msec/cm for the data in the right column. Time constants were set at 0·1 c.p.s. and 10 kc/s and the amplifier was a.c. coupled to the recording oscilloscope

* Preparation moved closer to light source. The relative intensity was not calculated.

rise time of the B wave being superimposed on the A_2 potential would add to the confounding of the apparent time of peaking.

Let us consider that the early part of the electroretinogram is a simple sum of the photopic and scotopic responses. They may have somewhat different onset latencies and widths so that they are disposed in such a manner that the A_1, presumably photopic, peak coincides in time with the rising slope of the A_2, probably scotopic, wave. The A_2 peak coincides with the falling slope of the A_1 wave, which is identical with the front slope of the first B wave component. Also, three further simple assumptions are consistent with recent observations on rabbit and cat retinæ: (1) the shapes of the waves are not substantially altered by increases in the intensity of illumination by white light; (2) their onset latencies change less than the apparent peak times; (3) both waves increase with intensity, but over an intermediate range the A_1 wave emerges out of the noise background and surpasses the A_2 wave amplitude. Therefore, we might say that a most significant dependent variable is the ratio (r) of the amplitude of A_1 to that of A_2.

We are interested in determining when the sum, $f(t)$, of the A_1 and A_2 time functions, $f_1(t)$ and $f_2(t)$, reaches a maximum; which is equivalent to asking when $\frac{df(t)}{dt} = f'(t)$ becomes zero. However, according to our assumptions the waves can be factored into amplitude factors, g and h, which depend on stimulus intensity and time course factors, $f_{11}(t)$ and $f_{22}(t)$, which do not.

$$f(t) = g\,f_{11}(t) + h\,f_{22}(t)$$

$$f'(t) = g\,f_{11}'(t) + h\,f_{22}'(t) = 0$$

at either of the two possible apparent peaks. Or if we consider only practical cases where g and h are both non-zero and $f_{11}'(t)$ and $f_{22}'(t)$ are not simultaneously zero:

$$\frac{1}{h} f'(t) = r f_{11}'(t) + f_{22}'(t) = 0$$

This shows that the time at which $f'(t)$ reaches zero depends on r, therefore on intensity, even though the time shapes of the individual processes do not.

From the last equation, a qualitative description can be made of the variations in the timing of the two peaks with changes in intensity. As the intensity increases both A_1 and A_2 waves should appear to peak earlier. The apparent time of the A_1 wave peak approaches asymptotically the real time of the A_1 process peak. This should serve as a reminder that changes in timing may be more apparent than real, and one must be quite careful when analysing the results to distinguish real latency changes from confounded interacting events.

As already mentioned, the pictures obtained in this series were taken under a rather extraordinary condition which was so manipulated that we were able to observe these events. We would suggest, however, that the temporal relationships of the A_1 and A_2 waves in normal preparations and their summing with each of the subsequent positive potentials may result in the double-peaked activity observed many times in the ordinary B waves[8]. Furthermore, when using chromatic stimulation the interaction would be even more complicated due to the hue-induced changes in shape of at least the A_1 wave represented in the equation as $f_{11}(t)$ (ref. 3).

'Safety Valve' Effect of Excess Dietary Amino-acids and Protein on Food Intake in Hyperphagic Rats

IMBALANCES in amino-acids and excessively high-protein content of the diet (66 per cent or more) depress food intake and retard growth in rats. It has been suggested that resulting metabolic disturbances affected the mechanism of regulation of food intake. The fact that in some instances administration of insulin counteracts the growth-retarding effect of leucine excess was taken as supporting this view[1]. Going one step further, it has been suggested that blood amino-acid patterns played a crucial part in the mechanism of satiety and the regulation of food intake[2,3]. The experiments presented here were designed to show whether excess or imbalanced amino-acid and protein intake do, in fact, act on the mechanism regulating food intake or whether they limit food intake by acting through other structures. Inasmuch as it has been shown that the ventromedial hypothalamic area regulates food intake, that is, adjusts food intake to energy output[4], apparently by inhibiting constantly activated lateral 'feeding centres'[5] and exercising some measure of control over gastric contractions[6], the animals used were ten female albino rats (Charles River strain) the 'satiety' centres of which had been destroyed by electrocoagulation of the ventromedial area.

The success of the operation had been established by allowing the animals to become obese (their weight had

gone from 275 g to an average of 562 g); the animals had then been reduced to 425 g to bring them back to the 'dynamic' phase of hypothalamic hyperphagia. They were then adapted for a period of four days to a control low-protein, semi-synthetic diet containing 9 per cent casein (*L* 1) supplemented with 0·3 per cent *d,l*- methionine and 0·1 per cent *d,l*-tryptophan. At the fourth day, protein depletion had apparently ceased, and, on the fifth day, five of the animals were put on a diet (*L* 5) in which 5 per cent of the sucrose in *L* 1 had been replaced by *l*-leucine. The remaining animals stayed on *L* 1. After five days, the two groups were switched. Food consumption and weight were recorded daily. Except for one rat, daily food intake on *L* 5 fell to 25–50 per cent of food intake on *L* 1. (Average daily intake 22·9 g/day on *L* 1; 10·3 g/day on *L* 5.) Weight was correspondingly affected. The depression of food intake by a dietary excess of leucine is thus obviously not mediated by the satiety centres.

We next explored the possibility that limitations of the ability to metabolize protein affects food intake through a structure other than the satiety centres. The 10 hyperphagic rats were placed on a series of semi-synthetic diets[7] containing 40–90 per cent casein and daily intake determined. The diets were fed five days each in the following order: 60, 40, 70, 50, 80, chow, 90 per cent. This order was chosen to preclude a progressive adaptation.

Table 1 gives the average daily intake for each animal on each diet, with the average amount of protein ingested daily. It is clear that for most animals there is a range (50–80 per cent of protein) over which the amount of protein ingested is relatively constant. In this range, which incidentally represents protein-levels in considerable excess of what would be found in natural diets, caloric intake is insufficient to maintain body-weight. Larger animals with the greater intakes at the lower protein-levels tend to be better able to maintain the limiting protein intake over a wide range of dietary protein-levels. In the 10–40 per cent protein range, protein-level does not influence intake.

The limitation of food intake in hyperphagic animals fed abnormally high protein diets so that protein intake does not exceed a limiting value is obviously independent of the presence of the ventromedial satiety centres. It differs in principle from the homeostatic control of food intake in that it does not equate energy intake to energy output. It appears to act like a 'safety valve', preventing the excess ingestion of protein rather than like a servomechanism. Limitation of food intake by amino-acid excess or imbalance may be the result of a similar phenomenon. The classic experiments of Kennedy[8] on the effect of heat on hypothalamic hyperphagic rats can be interpreted again as demonstrating a similar 'safety valve' effect for heat and dehydration.

HÆMATOLOGY

Stimulation of Factor VIII (Antihæmophilic) Activity by Transfused Serum

Patients with factor VIII deficiency and prolonged skin bleeding time (von Willebrand's syndrome) who receive fresh blood or plasma from normal donors or from patients with hæmophilia *A* with very low factor VIII activity show a much higher factor VIII activity in their plasma than could possibly be explained by the amounts given. The maximum factor VIII activity is reached 4–8 h after transfusion and persists longer than in hæmophilia *A* (refs. 1 and 2).

The prolonged skin bleeding time may be temporarily shortened. The component responsible for the factor VIII stimulation has not been distinguished from that associated with the skin bleeding time.

Evidence is presented which suggests that the two factors are different.

A 21-year-old male (D. W.) with a bleeding tendency since infancy has approximately 10 per cent of factor VIII

Table 1

Patient	Transfusion data				Factor VIII activity				Skin bleeding time 10 min after transfusion (min)
	Material	Volume (ml.)	Factor VIII activity (*a*) (ml.)	Duration of transfusion (min)	Before transfusion (%)	Expected activity (*b*) (%)	Observed activity (%)	Time after transfusion (h)	
Von Willebrand's disease (D. W.)	Plasma (*c*)	1,000	1,000	37	14	33	62	4–8	7
	Serum (*d*)	1,100	<11	65	9	10	82	8	>20
	Plasma fraction I-0 (*e*)	180	540	15	10	27	42	14	12
Hæmophilia *A* (R. C.)	Plasma fraction I-0 (*f*)	700	1,800	54	<1	44	35	1	—

(*a*) Expressed as ml. of plasma with 100 per cent normal factor VIII activity. (*b*) Calculated on basis of simple mixing. (*c*) 9 vol. of normal blood added to 1 vol. of a solution containing 0·053 M citric acid and 0·105 M trisodium citrate, plasma obtained by centrifugation and stored at −20° C for 30 days. Thawed and warmed to 37° C immediately before use (Fig. 1, curve ○). (*d*) Blood collected without anticoagulant; kept at room temperature for 24 h, centrifuged, serum collected, stored for 24 h at room temperature and then 24 h at 2° C (curve ●). (*e*) Dry preparation from 1,650 ml. of A.C.D. plasma reconstituted (curve ▲). (*f*) As for (*e*) but from 4,900 ml. of A.C.D. plasma (curve ■).

activity in his plasma and his skin bleeding time is consistently in excess of 20 min, except after blood transfusions. His plasma volume is assumed to be 3 litres. He has been transfused successively with plasma, serum and plasma fraction I–0 (ref. 3). Factor VIII determinations in plasma and skin bleeding time were performed at intervals. The relevant results are shown in Table 1 and Fig. 1 and are compared with that of a patient (R. C.) with severe hæmophilia *A* (less than 1 per cent plasma factor VIII) whose plasma volume is assumed to be 3·5 litres. The results after transfusion observed in R. C. are typical of those seen in hæmophilia *A* in which the half-life of transfused factor VIII is between 5 and 15 h. In the case of D. W. the plasma factor VIII activity rose much higher than expected following transfusion of plasma or serum. In addition the skin bleeding time was shortened after the transfusions of plasma or of the plasma fraction I–0 but the serum transfusion did not shorten the skin bleeding time. Factor VIII activity was assayed by two independent techniques (partial thromboplastin time and thromboplastin generation), using plasma with less than 1 per cent factor VIII from hæmophilia *A* patients. Non-specific effects were excluded. It is believed the results represent true factor VIII-levels.

The observations suggest that normal plasma contains two components which are lacking in patients with von Willebrand's syndrome. The component which stimulates factor VIII activity *in vivo* is present both in citrated plasma (*p*H 7·1) stored at −20° C for 30 days and in serum. Only a low activity is present in lyophilized plasma fraction I–0. The second component which shortens the bleeding time is present in frozen plasma and plasma fraction I–0, but is absent from serum.

Potentiation of factor VIII activity occurs in normal persons and hæmophilic patients with measurable levels of plasma factor VIII immediately after exercise[4] or adrenaline infusion[5], and a rise of factor VIII activity occurs in normal persons 1–3 days after serum infusion[6]. There is no obvious relation between these observations and the reported experiments.

The clinical implications will be reported separately.

We thank the Red Cross Blood Transfusion Service, Melbourne, for the supply of blood and blood products. This work was supported by a grant-in-aid from the National Health and Medical Research Council, Canberra.

Correlation between Rheumatic Diseases and Rh Blood Groups

We have recently determined the blood groups of 99 patients with some variety of articular disease (31 with rheumatoid arthritis, 31 with rheumatoid spondylitis, 15 with gout, 9 with disseminated lupus erythematosus, 6 with familial Mediterranean fever, and 7 with various other diseases). Statistical analyses demonstrated no significant heterogeneity among the results obtained for the different diseases. Accordingly, the data were pooled. For comparison we used Wiener's series of 1071 New York Whites[1], as in a previous investigation[2]. There is a significant correlation between the absence of the Rh antigen D and rheumatic disease, as shown in Table 1. No correlation was found between the presence of rheumatic disease and antigens C or E, or with the ABO blood group system. There did, however, seem to be a correlation with the absence of antigen N ($\chi^2_{(2)} = 9{\cdot}59$, $P = 8 \times 10^{-3}$).

Table 1

	Rhesus type		
	D+	D−	Total
Articular disease	71	28	99
Normals (New York City)	902	160	1,071

$\chi^2_{(1)} = 10{\cdot}12$, $P = c.\ 1{\cdot}5 \times 10^{-3}$.

Changes in the Concentration of Potassium in the Erythrocytes and in Hæmoglobin Type in Merino Sheep under a Severe Anæmic Stress

Most breeds of sheep are polymorphic with respect to the concentration of potassium in their erythrocytes (70–90 m.equiv. K^+ (*HK*) or 10–20 m.equiv. K^+ (*LK*) per litre of red cells[1]) and hæmoglobin type (Hb A, B or AB[2]). High concentrations of K^+ (approximately 110 m.equiv./l.), which fall to normal adult levels 60–100 days after birth, are found in the erythrocytes of all fœtal lambs[3]. In the erythrocytes of normal adult sheep the mean concentration of potassium remains relatively

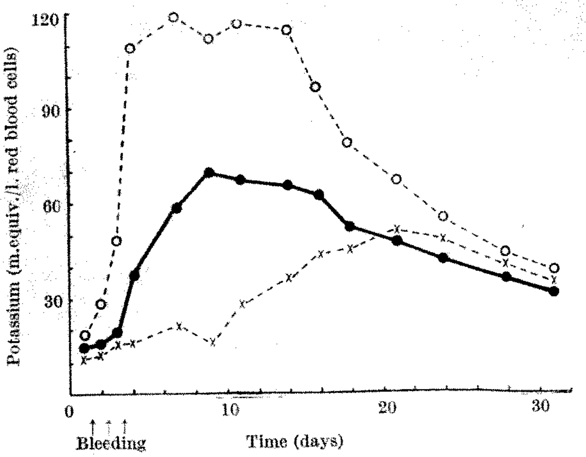

Fig. 1. The mean concentrations of potassium (m.equiv./l. of cells) from the total erythrocyte population (●) and from the top (○) and bottom (×) layers of red cells separated by centrifugation, during an experimental anæmia of a sheep

constant over long periods[4], but during an anæmic episode in *LK* animals the concentration is markedly increased[5].

This rise in the concentration of K^+ has been investigated in 8 *LK* sheep rendered anæmic by experimental loss of blood, and a significant correlation between the percentages of reticulocytes and the mean concentrations of K^+ in erythrocytes has been obtained ($r = 0\cdot8$, $P < 0\cdot001$). As young erythrocytes from man have been shown to be concentrated in the top layers of a centrifuged column of red cells and to have a higher concentration of K^+ than older cells[6], the erythrocytes from the top and bottom fractions of a centrifuged column from *LK* sheep were separated before and during an experimental anæmia. Reticulocyte counts and concentrations of potassium were determined on both fractions from nine *LK* sheep and a typical result for the changes in intracellular K^+ is shown in Fig. 1.

There was a marked rise in the concentration of potassium in the top layer of cells during the course of the anæmia, and this later also showed a very high percentage of reticulocytes as opposed to the bottom layer in which K^+ did not show a similar rise and reticulocyte counts were negative throughout.

The rise in the mean concentration of potassium in erythrocytes during an anæmic episode would therefore appear to be due to the influx of large numbers of young cells with very high concentrations of potassium.

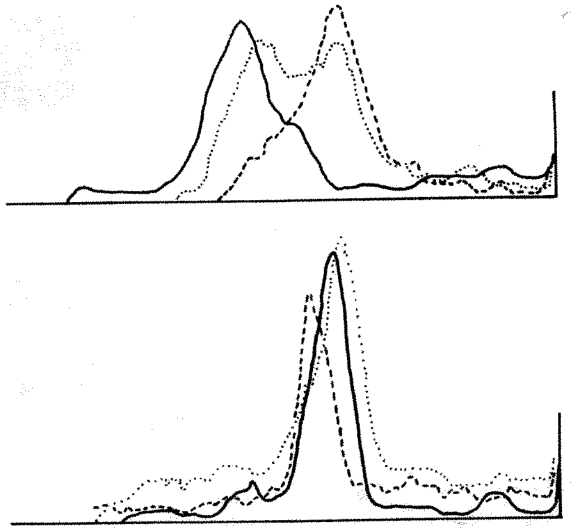

Fig. 2. Scan patterns of hæmoglobin electrophoretograms of unseparated cells (above, hæmoglobin type A; below, hæmoglobin type B) (non-anæmic control period: ———, anæmic period: ....) and separated top cells (– – – –) from sheep with hæmoglobin type A and type B

The electrophoretic patterns of hæmoglobins (*tris*-borate buffer *p*H 9·2) from aliquots of the total erythrocyte population and the top cell layers from hæmoglobin *A* and hæmoglobin *B* sheep were also examined before and during the experimental anæmia. Typical results are shown in Fig. 2. A new hæmoglobin was present in sheep with type A hæmoglobin, but in sheep with type B hæmoglobin the evidence, although suggestive, was not conclusive.

This latter response to anæmia could be due to the production of fœtal hæmoglobin and the association of the new hæmoglobin in the anæmic adult with cells with high concentrations of potassium, similar to those found in fœtal and new-born lambs, would support this. There is reason, however, to believe that it could be a new hæmoglobin, electrophoretically similar to hæmoglobin B and different to fœtal hæmoglobin, which is associated with immature red cells.

A hæmoglobin, distinct from the normal adult type and associated with immature red cells, has been suggested in the rabbit[7] and rat[8].

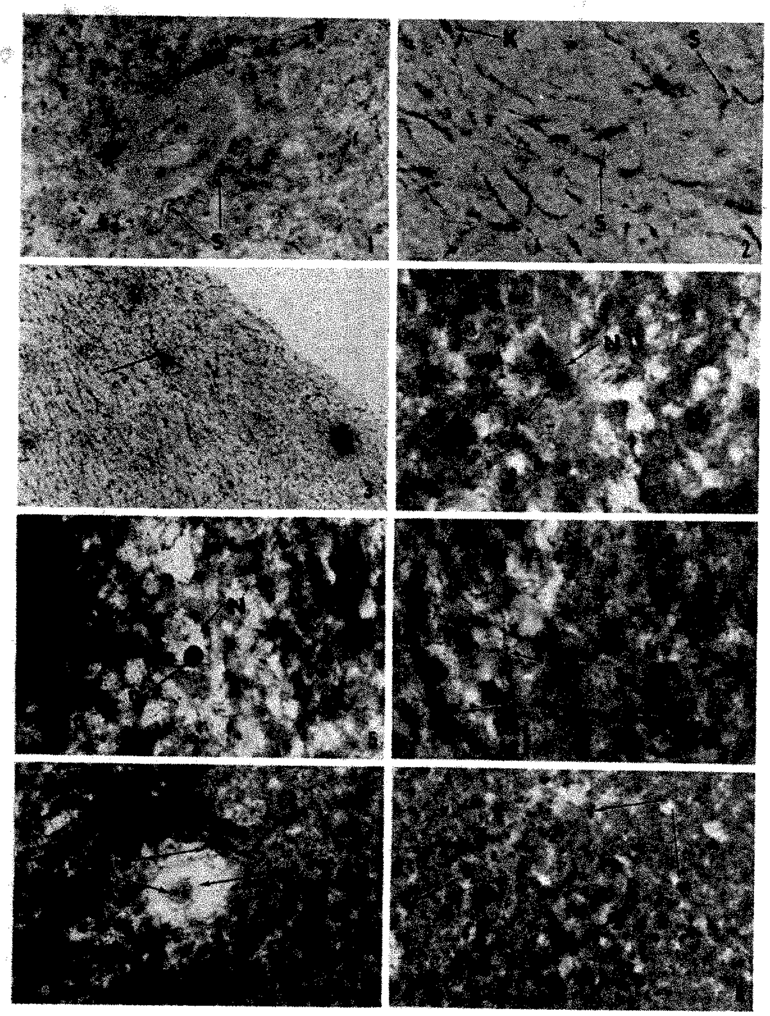
HISTOCHEMISTRY

Alkaline Phosphatases in Brain and Spinal Cord

THERE has been much controversy as to whether alkaline phosphatase is a single enzyme or whether a number of such enzymes are present in tissues. The evidence derived from inhibition and *p*H studies suggests the existence of a plurality of alkaline phosphatases[1-3]. The subject has been studied histochemically by Glick and Fischer[4], Dempsey[5], Friedenwald and Maengwyn-Davies[6] and Bourne[7]. The results of these authors also suggest a multiplicity of alkaline phosphatases. Sandler and Bourne[8] separated out a number of substrate specific phosphatases by starch-gel electrophoresis, thus again indicating the plurality of alkaline phosphatase.

In the present study, fresh frozen sections of spinal cord (15μ) and cerebral cortex (10μ) of rat were examined by the methods of Burstone[9] and Gomori[10] for alkaline phosphatase, the period of incubation being 2 and 3 h, respectively. The control tests were performed by boiling the sections before incubation and also by incubating without the substrate. Paraffin sections (10μ) have also been stained by silver nitrate[11] to demonstrate the nerve endings in the spinal cord.

With Burstone's method the neurones of the spinal cord were negative even after prolonged incubation (Fig. 1). Although the cells and their processes were negative, the synaptic regions, both on the cell surface (Fig. 1) and on the cell processes, showed a positive reaction in the form of granular deposits. The distribution of such reactions corresponded closely to the distribution of endings found by Bodian's method[11]. The blood vessels and the pia-arachnoid gave a positive reaction.



All preparations are of fresh frozen sections

Fig. 1. Alkaline phosphatase reaction (ref. 9). Neurone of the spinal cord. Note positive reaction in the synaptic regions (*S*) on the surface of the cell and around, although the cell itself is negative (× 750)

Fig. 2. Alkaline phosphatase reaction (ref. 9). The plexiform layer of the cerebral cortex. Note positive reaction in the cell processes and synaptic regions (*S*). Note also the positive knob-like synaptic areas (*K*) (× 750)

Fig. 3. Alkaline phosphatase reaction (ref. 9). Plexiform layer of the cerebral cortex. Note positive reaction in the synaptic region (arrow) (× 75)

Fig. 4. Alkaline phosphatase reaction (ref. 10). Neurone of the spinal cord. Note reaction is most intense in the nucleolus (*n*), less in the nucleus (*N*) and still less in the cytoplasm (× 750)

Fig. 5. Alkaline phosphatase reaction (ref. 10). Neurone of the spinal cord. Note intense reaction in nucleolus (*n*), mild reaction in the cytoplasm and almost negative in the nucleus (*N*) (× 750)

Fig. 6. Alkaline phosphatase reaction (ref. 10). Grey matter of spinal cord. Note positive reaction in the nerves (*P*) and their synaptic regions (*S*) (× 750)

Fig. 7. Alkaline phosphatase reaction (ref. 10). Neurone of the cerebral cortex. Note the two rounded positive bodies (*nb*) inside the nucleolus. Note also positive reaction on the cell surface probably indicating sites of synaptic areas (*S*). The nuclear wall (*N*) shows a mild reaction. The blood vessels (*B*) also show a strong reaction (× 750)

Fig. 8. Alkaline phosphatase reaction (ref. 10). Plexiform layer of the cerebral cortex. Note positive reaction in the knob-like synaptic areas (arrows) in that region (× 750)

Burstone's method gave a similar picture in the cerebral cortex. The nerve cells were almost completely negative. In spite of the absence of reaction from the cells, the synaptic regions always exhibited a positive reaction of moderate intensity, both around the cells and along the fibres (Figs. 2 and 3). The latter picture was most conspicuous in the plexiform layer of the cortex (Figs. 2 and 3). The pattern of reaction in such regions was either in the form of fine beads or larger knobs around the cells and along their processes.

A markedly different picture was observed with Gomori's method in the spinal cord. The nucleolus of each neurone always gave an intensely positive reaction; however, the nucleus and cytoplasm varied in different neurones from a faint diffuse reaction to a moderately strong one (Figs. 4 and 5). The processes of the neurones showed a positive reaction. A reaction was demonstrated also in the nerve processes forming a plexiform arrangement around the neurones, in the synaptic regions between one neurone and the processes of another and between the processes of different neurones (Fig. 6). This was also evident in paraffin sections of the spinal cord. Some neurones showed patches of intensely positive reaction in their cytoplasm, which may indicate the presence of the enzyme in lipofuscin pigments.

In the cerebral cortex the enzyme was located by Gomori's method in the nucleolus, nucleus and cytoplasm of the cells. The reaction was most intense in the nucleolus in the form of fine granules distributed unevenly. It was interesting to note the presence of round positive bodies, which varied in number, in the nucleolus, and these always exhibited a stronger reaction than the rest of the nucleolus (Fig. 7). The nucleus and cytoplasm showed positive reactions of varying intensity. The cell processes also showed a positive reaction which was finely granular and mainly located near the synaptic regions around the cells, and also along the fibres. The presence of a positive reaction in such regions was more marked in the plexiform layer of the cortex, which exhibited knob-like, positive bodies distributed unevenly (Fig. 8). Apart from the neurones, the blood vessels and the pia-arachnoid also showed a strong reaction as in the spinal cord.

A histochemical study of the enzymes in different parts of the central nervous system was carried out by Bourne[7] and by Tewari and Bourne[12]. Bourne[7], using Gomori's method for alkaline phosphatase in the brain, suggested that the possible role of phosphatases in synaptic transmission should be considered. The localization of this enzyme in the wall of the blood vessels and at the synaptic regions may be perhaps reconciled by the suggestion that this enzyme may be related to the alteration of permeability and supply of free energy. Bourne[13] also noticed increased hydrolytic activity in senescent cells.

The work recorded here suggests that at least in the spinal cord and cerebral cortex the Burstone reaction for alkaline phosphatase demonstrates a different enzyme from that shown by Gomori's technique. This is supported by the starch-gel observations of Sandler and Bourne[8].

Histochemical Localization of Choline Oxidase in Rat Liver and Kidney

RAT liver is capable of oxidizing hydrolysed acetylcholine[1]. It was shown to be due to oxidation of choline, and betaine aldehyde is the oxidation product[2]. The oxidase system involved was found to consist of a dehydrogenase, choline dehydrogenase, cytochrome *C* and cytochrome oxidase[3]. Though this enzyme system does not need diphosphopyridine nucleotide (DPN), yet it is sensitive to the action of amytal[4]. This oxidase system is also sensitive to antimycin *A*, cyanide and azide, but to a much lesser extent than that of succinic oxidase system[5]. These findings indicate that a respiratory chain identical to that of succinic oxidase may be involved in the hydrogen transfer from choline. According to some authors, flavin adenine dinucleotide (FAD) may be involved in this reaction[6], but by others it plays no part at all[7]. Choline oxidase activity was studied biochemically using different hydrogen acceptors as ferricyanide, methylene blue, cytochrome *C*, 2,6-dichlorophenol indophenol[8] and triphenyl tetrazolium bromide[9]. But phenazine methosulphate was found to be the only reliable hydrogen acceptor for purified choline dehydrogenase[7]. This oxidase may play an important part in the transfer of labile methyl group to methionine[10].

Young and adult rats, 5 guinea pigs, two rabbits and one cat, were bled after light ether anæsthesia. Tissues were immediately frozen in liquid nitrogen and were carried to the cryotome. Some biopsy material of human skin and cirrhotic human liver were also examined. These unfixed tissues were sectioned in a cryostat-microtome at 8–10μ. The sections were collected on coverslips and dried in air for 10 min. Air-dried sections were put directly into the incubation medium. The incubation medium is composed of 3·5 mg of choline chloride (about 0·005 M), 1 mg of nitroblue tetrazolium ('Nitro *BT* Grade III' of Sigma) dissolved in 5 ml. of 0·05 M phosphate buffer at *p*H 6·9. Incubation time varied from 30 min to 1 h. After incubation, sections were treated with neutral formol for 10 min, then washed with distilled water and mounted in Apathy's syrup. In some cases incubated sections were quickly dehydrated and were mounted in Canada balsam. Control reaction was carried out without choline chloride in the incubation medium.

Among rat tissues, only liver and kidney showed an activity, while cerebellum, sub-maxillary salivary gland, thyroid, spleen and adrenal gland showed no activity at all. Rat pancreas was coloured only feebly. Guinea pig liver, as excepted[1], was totally devoid of choline oxidase activity. Neither cat liver nor rabbit liver showed any appreciable activity. Unaffected parenchyma of human liver could scarcely show any activity. Human skin was entirely negative to this reaction. Rat liver showed a more intense activity in the parenchymal cells of the perilobular region and in the parenchymal cells around the blood vessels, while the cells of the centrolobular region show moderate activity (Fig. 1). This activity is revealed by the deposition of violet granules of formazan. But this deposit turns blue when the section is dehydrated. In rat kidney only the cortical portion shows a positive reaction. In the cortex, proximal and distal convoluted tubules are positive to the choline oxidase activity, while glomeruli and loops of Henle are entirely negative (Fig. 2). Medullary rays passing through the cortex are entirely negative. Collecting tubules are devoid of this activity. The reaction is usually more intense in the basal part of the tubular cells than that in the apical part. This is probably due to larger concentration of mitochondria in the basal part of these cells. Walls of the blood vessels are devoid of any activity.

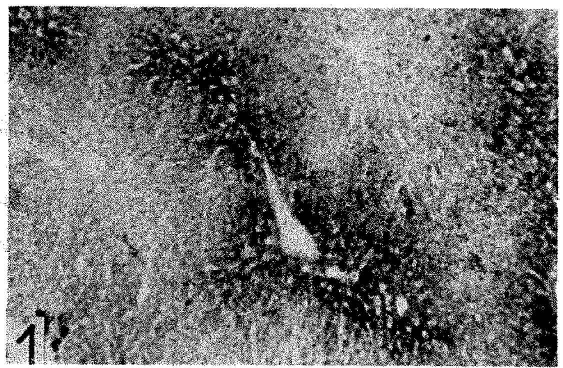

Fig. 1. Choline oxidase activity in rat liver. Activity is intense in perilobular region

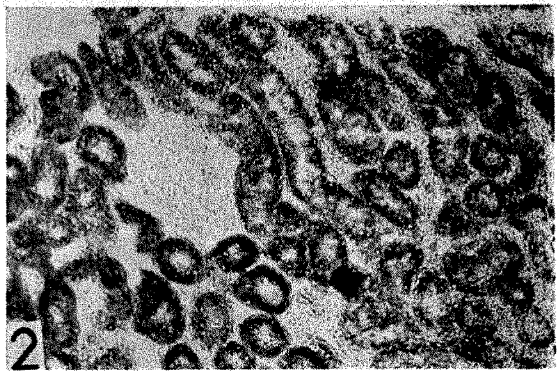

Fig. 2. Activity of choline oxidase in rat kidney cortex. Activity is present in the proximal and distal convoluted tubules

Both chloride and hydrochloride forms of choline can serve as substrate in this reaction. When acetylcholine or butyrylcholine was substituted for choline in the incubation medium, no reaction could be obtained. But substitution by succinylcholine showed a feeble activity. This reaction may be due to quicker hydrolysis of succinylcholine than that of acetyl- or butyryl-choline.

Several experiments were done in order to dissociate the respiratory chain used by the choline oxidase system. Previously neutralized solution of potassium cyanide (0·004 M) was added to the incubation medium; but no appreciable diminution of choline oxidase activity was observed. Nor was cytochrome oxidase inhibited by potassium cyanide at that concentration. Sodium azide also did not inhibit the choline oxidase activity. Added cytochrome *C* (10^{-4} M) did not increase choline oxidase activity. These results, however, are in agreement with biochemical findings[5]. Betaine chlorohydrate, at an equimolar concentration of choline, completely inhibited choline oxidase activity. It is considered that phenazine methosulphate is the only reliable hydrogen acceptor for purified choline dehydrogenase[7]. In an attempt to dissociate the respiratory chain, unfixed sections of tissues were left overnight in phosphate-buffered solution made isotonic with sucrose. No activity could be obtained in these pretreated sections. Since choline dehydrogenase is insoluble in water[6], this inhibition may be due to disruption of the respiratory chain. But addition of phenazine methosulphate did not restore this activity. Some sections were fixed in absolute alcohol at −30° for a period ranging from 1 to 18 h. These sections were deprived of their usual choline oxidase activity; but the addition of phenazine methosulphate in the incubation medium did show an activity in alcohol-fixed sections of rat liver and kidney. It was found that cold alcohol renders choline dehydrogenase insoluble without destroying its activity[10]. It appears that this hydrogen transport through phenazine methosulphate in alcohol-treated sections may be due to the dehydrogenase component alone of this oxidase system. Further tests are being carried out in order to find out whether there is a real dissociation of the choline dehydrogenase from its respiratory chain. Sections fixed in acetone at −30° for a short time retained choline oxidase activity, while overnight fixation totally destroyed it. Even phenazine methosulphate in the incubation medium could not restore this activity. This finding, however, is in contradiction with an anterior histochemical finding of Chang and Hori[11], who found that choline dehydrogenase could be demonstrated after fixation in acetone in dry ice temperature, in the presence of phenazine methosulphate.

Highest activity was obtained between *p*H 6·8 and 7·4. At *p*H 6·0 choline oxidase activity is totally absent, while at *p*H 7·9 this activity still persists. Only phosphate buffer was found to give a satisfactory result. Triethanolamine buffer totally inhibits this reaction. A comparison was made with succinic oxidase activity. Though both succinic and choline oxidase activity were found to be variable yet the reaction of choline oxidase is approximately half as intense as that of succinic oxidase. When choline and succinate are added together in the incubation medium, often an additive effect is observed which may indicate the absence of competition between succinic and choline dehydrogenase for the respiratory chain.

HISTOLOGY

Isolation of Nuclei from Avian Erythrocytes by Partial Electrocytolysis

INVESTIGATION into the presence of hæmoglobin and its possible synthesis within the nucleus of primitive erythroblasts obtained from chick blood islands cultured *in vitro*[1] has indicated the desirability of a micro-method to isolate nuclei from relatively small numbers of cells[1,2].

The mature nucleated red cell of the adult bird or amphibian represents a useful test system. It is simple to obtain a suspension of free cells, and, in addition, the protein hæmoglobin is found in both cytoplasm and nucleus. During an electrocytolytic process, as with any isolation technique, the boundary surface of the nucleus may be modified. Consequently it is important to be able to assess the extent of nuclear protein loss. The nuclear hæmoglobin is easily identifiable, and this protein therefore affords a valuable means of making such assessment.

The method involves the controlled electrolytic breakdown of the cell wall, the electrophoretic removal of cytoplasmic debris and the ultimate isolation of the nucleus.

The cells are suspended in a fluid medium or in an agar gel. The gel has advantages in the control of partial cytolysis and where the sample is small. The latter circumstance imposes the necessity for a restriction of electrophoretic mobility so that cells remain localized for subsequent treatment. Both methods may be combined with direct microscopic observation. It has been found simple and convenient to form the reaction space using a 1 per cent agar gel on a 3 in. × 2 in. glass slide. When cells are suspended in a fluid medium a coverslip over the space restricts the sometimes rapid fluid depletion due to electrolytic diffusion and possible electro-osmosis. A coverslip also facilitates microscopic observation and allows the slide to be orientated at any required angle so as to utilize, if desired, the different sedimentation rates of nuclei and cytoplasmic debris. The components of the cytoplasm and nucleus undergo electrophoresis and may be localized and detected in the gel by suitable methods. In this particular case there is early diffusion of cytoplasmic hæmoglobin into the gel. Later, if the process is carried far enough, nuclear cytolysis occurs and nuclear hæmoglobin is similarly liberated. The hæmoglobin may be detected in the gel by its catalase reaction with *o*-dianisidine[3].

The following media were used: Pannett–Compton saline, Hanks's medium, Tyrode and Ringer. Buffers included Sorensen's phosphate, citrate–hydrochloric acid, and veronal–hydrochloric acid. The range of initial *p*H has extended from 3·0 to 10·0. The variation in *p*H throughout the electrolysis varies with the medium used, the degree of buffering and the initial *p*H. The electrolytic ionization involved, especially in the gel medium, is very complex and is doubtless the effector mechanism bringing about the cytolysis. As yet no serious investigation of the physical-chemistry of the reacting system has been undertaken.

The field intensities used were 20–100 V/cm, the current 5–70 m.amp. and the temperatures 18°–20° C.

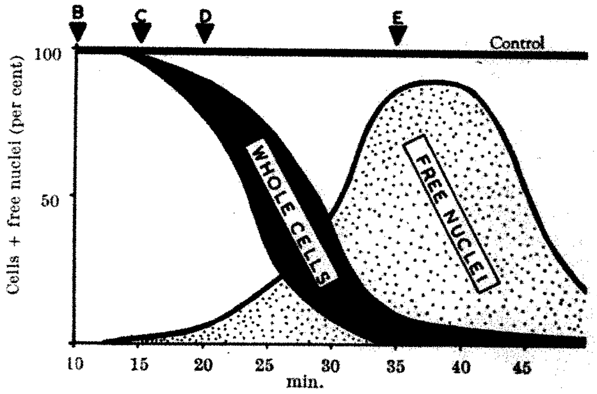

Fig. 1. No. of whole cells (that is, cell wall intact) and free nuclei expressed as a percentage of the total (whole cells + free nuclei) in relation to the time of electrolysis. Control suspension of cells shows no cytolysis; shaded region (percentage of whole cells) indicates degree of variation between experiments. Stippled region (percentage of free nuclei) falls away as nuclei cytolyse. Arrows at points 10 min, 15 min, 20 min, 35 min represent periods when the cells shown in Fig. 2*b*, *c*, *d*, *e* were sampled. Medium: Pannett–Compton sucrose saline buffered to *p*H 5·5 with Sorensen phosphate. Field intensity, 100 V/cm; current, 25 m.amp; temperature, 18° C

Fig. 1 summarizes a reaction in which the cells were suspended in a Pannett–Compton sucrose saline buffered to *p*H 5·5 with Sorensen-phosphate. The curves express the percentage of whole cells (cell wall intact) and the percentage of free nuclei in the combined total (cells plus free nuclei). Cell counts are made in two ways: (*a*) at intervals of time the reaction is stopped by breaking the circuit, electrophoretic movement allowed to cease and counts made in a succession of microscopic fields along the centre line of the reaction space (× 40 Cooke–A.E.I. long working distance semireflecting objective and green filter); (*b*) at similar intervals the reaction is stopped, the slide taken from the apparatus, coverslip removed and the whole gel treated with formol–acetic alcohol vapour. When the circuit is broken electrocytolysis ceases. After drying the slide and removing the agar it is stained in Weigert's hæmatoxylin and light green. Cells and free nuclei are then counted in the same way. As might be expected, method (*b*) yields a higher percentage of free nuclei than method (*a*), but this does not alter the general picture.

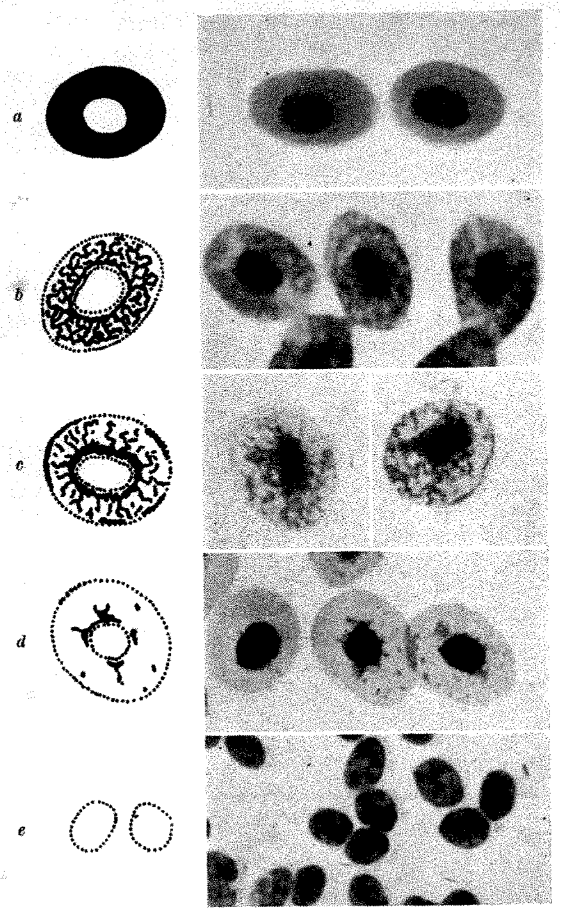

Fig. 2. Avian erythrocytes during partial electrocytolysis stained in Weigert's hæmatoxylin and light green. Cells suspended in Pannett–Compton sucrose saline buffered to pH 5·5. Shaded diagrams on left-hand side indicate the distribution of the light green cytoplasmic stain. *a*, Erythrocytes at 0 min; *b*, 10 min; *c*, 15 min; *d*, 20 min; *e*, 35 min. Field intensity, 100 V/cm; current, 25 m.amp.; temperature, 18° C. Zeiss photomicroscope, magnification on film (× 224)

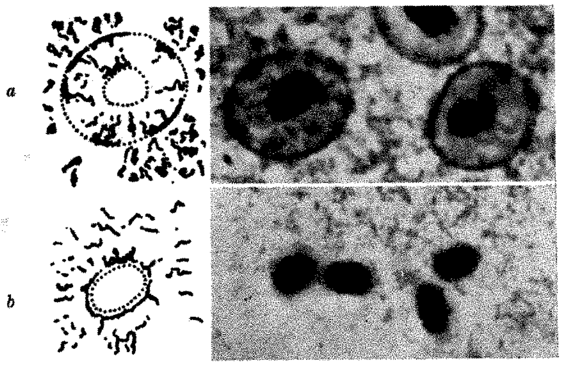

Fig. 3. Cells suspended in 0·6 per cent agar gel made up with Pannett–Compton sucrose saline buffered to pH 5·5. Experimental conditions as in Fig. 2. *a*, 15 min; *b*, 35 min. Note the light green positive material in the gel while cell wall remains intact

The arrows indicate points at which samples were taken and Fig. 2*b–e* demonstrates the morphology of the cells at corresponding times. The cytoplasmic distribution of substances reacting with the light green stain is markedly altered. Fig. 2*d* poses the question whether the substance formerly reacting with the stain is present but no longer stained, or whether it has left the cell. Fig. 3*a* represents the same stage in time as Fig. 2*d* when the reaction occurs in an agar gel. The extracellular material is stained by the light green and is present at a stage prior to the breakdown of the cell wall in all but a very few cells, indicating a passage of cytoplasmic substance through the apparently intact cell membrane. The reaction of the nucleus with hæmatoxylin shows no diminution at this time. Fig. 3*b* corresponds to Fig. 2*e* and demonstrates a persistent but indistinct zone of light green positive material around the nucleus for a short time when the electrocytolysis occurs in a gel.

It is realized that both avian and amphibian erythrocytes have particularly resistant and inactive nuclei that may lend themselves better than other cell nuclei to this process. In accordance with original intention, the technique is being extended to the primitive blood island erythroblast, and to disaggregated embryonic liver cells. It has been found possible to obtain free nuclei from trypsin and versene dissociated chick liver cells. Whether nuclei isolated in this manner are morphologically intact when viewed with the electron microscope, or, what is more important, whether they retain their metabolic activity and potential, is yet to be determined.

Orthogonal Diameters in the Analysis of Muscle Fibre Size and Form

Distributional changes in sizes of fibres have been correlated with pathological processes affecting muscle. Micrometry of muscle fibres in histological cross-section, for example, has been frequently used to follow the course of denervation atrophy[1]. Unfortunately, the complex polygonal form of the fibre and the lack of a standard technique of measurement make it difficult to compare the results of different studies[2].

A single arbitrarily selected diameter has been used by most investigators. The precise method of measurement has rarely been specified, however, and the data give no information on the configuration of the fibres. Cross-sectional fibre areas have occasionally been estimated[3], but planimetric measurements are too cumbersome for routine use and the method ignores variations in fibre form. Similarly, determinations of muscle weight[4] may be misleading and such data have no relevance to the examination of biopsy material.

The analysis of size of muscle fibre is obviously difficult to test by ordinary line and area criteria. More reliable information might therefore be obtained through the use

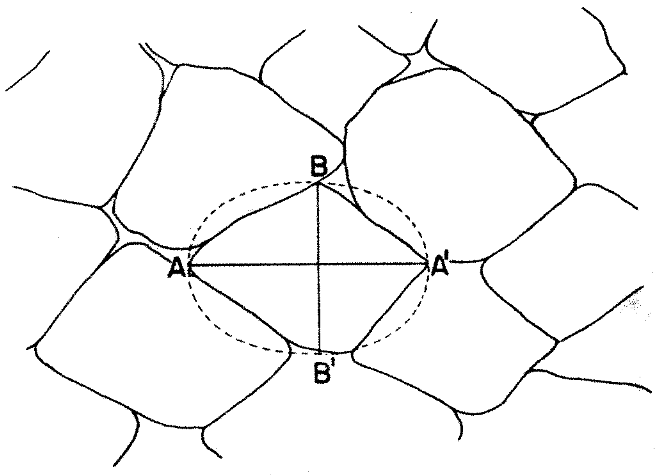

Fig. 1. Camera lucida tracing of transversely sectioned rat gastrocnemius muscle fibres (× *c*. 200). Definition of major and minor axis diameters is illustrated (*A–A'* = major axis, *B–B'* = minor axis). Broken line is drawn to demonstrate the irregular ellipse that can be proscribed around the polygonal muscle fibre

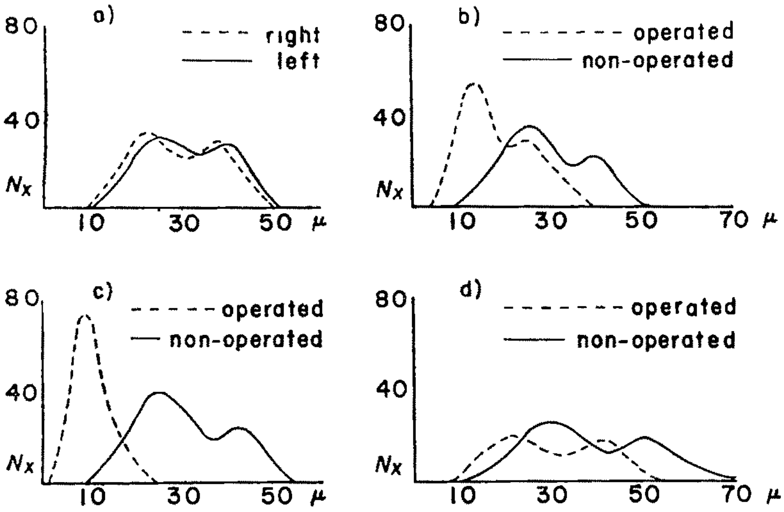

Fig 2 Size-frequency distribution of major and minor axes following denervation (N_x = 150 fibre measurements)
a, Normal non-operated rat (body-weight 120 g), *b*, one week after resection of right sciatic nerve bimodal distribution persists on the operated side, but major and minor axes show distinct shift to the left, *c*, four weeks operated side now shows unimodal distribution of fibre diameters, *d*, ten weeks following denervation recovery is confirmed by the return of a bimodal distribution of fibre diameters (body-weight 250 g)

of size metameters (for example, largest diameter, diameter in a given direction, circumference, etc) and form metameters (ratio of maximum to minimum diameter, ratio of circumference to area, ratio of outside to inside circle radii, etc)[5] After testing a number of possible measurements, it was found that two orthogonal diameters in the muscle fibre gave a reliable index of changing fibre size and shape

The polygonal form of the muscle fibre can be inscribed within a closed oval resembling an ellipse. The area of this form is proportional to its major and minor axes For purposes of measurement, the major axis is defined as the diagonal connecting the most distant angular points in the cross-section of the fibre The longest perpendicular offset from this major axis to the remaining angular points constitutes the minor axis (Fig 1) The biaxial diameter ratio is the ratio of the major axis to the minor axis. Adequate sampling of such measurements from a given muscle should provide a reliable indication of the average large and small diameters (major and minor axes), the size-frequency distribution of these diameters, and the average cross-sectional form of the fibres

This method was evaluated in gastrocnemius muscles of rats that had been subjected to 5-mm resections of the right sciatic nerve 1 day–6 months prior to death Identical muscle from the unoperated limb and from non-operated rats, matched for age, sex and weight, served as controls Muscle samples with a maximum thickness of 5 mm were briefly air dried on filter paper, fixed in Bouin's fixative, and embedded in paraffin with fibres oriented for longitudinal or transverse sections Paraffin sections were prepared with a Spencer rotary microtome set at a section thickness of 4μ An adjacent muscle sample was quenched in 2-methylbutane (isopentane) cooled with dry ice Comparison of unfixed cryostat sections with paraffin sections showed a shrinkage of 10 per cent in the latter. This reduction in size incident to fixation and embedding was uniform throughout the muscle bundle and there was no change in the cross-sectional form of the fibre Micrometry was performed at a magnification of 400 using a binocular microscope equipped with a calibrated eyepiece graticule Areas containing properly oriented cross-sections of muscle fibres in groups of 200 or more were selected from each section Obliquely oriented fibres and the edges of sections were avoided Major and minor axes were measured in each of 150 fibres Measurements were made in consecutive fibres by traversing the histological sections horizontally and vertically with a graduated mechanical stage to ensure uniform sampling

Table 1 Effect of Denervation on Orthogonal Diameters and Biaxial Diameter Ratio of Rat Gastrocnemius Muscle

Time after nerve resection (weeks)	Major axis diameter* (μ)	Minor axis diameter* (μ)	Biaxial diameter ratio
0 (control)	38 6 ± 0 89	28 3 ± 0 69	1 36
1	22 3 ± 0 48	17 1 ± 0 41	1 30
4	14 1 ± 0 82	12 3 ± 0 72	1 14
10	41 7 ± 1 48	27 6 ± 1 34	1 51

* Values expressed as mean ± standard error of the mean

The size-frequency distribution of the normal muscle is shown in Fig 2*a* The ellipsoid character of the muscle fibre is reflected in the bimodal distribution of major and minor axis diameters and the biaxial diameter ratio, which is greater than one (Table 1)

Throughout the early phases of atrophy (Fig 2*b*) the diameters were smaller than normal but a bimodal distribution persisted and the biaxial diameter ratio remained greater than 1, confirming the observation that no significant alteration in cross-sectional form of the fibre had occurred During the state of maximum atrophy (4–7 weeks, Fig 2*c*) the diameters were sharply reduced, the size-frequency distribution was narrowly unimodal, and the biaxial diameter ratio (close to unity) correlated with the tendency of the maximally atrophied fibre to assume a rounded form (Table 1) The phase of recovery (Fig 2*d*) was marked by the reappearance of a bimodal distribution of fibre diameters and a progressive increase in the biaxial diameter ratio

The method of orthogonal diameter measurement can therefore be recommended for the sizing of muscle fibres It gives more reliable data on the size-frequency distribution of fibre diameters and the cross-sectional form of the fibre can be accurately expressed by the biaxial diameter ratio (ratio of major to minor axis) The method is particularly suitable for the investigation of changes in distribution of fibre sizes and variations in fibre form.

RADIOBIOLOGY

Bone-marrow Mitotic Inhibition induced by Local Splenic X-irradiation

An increasing number of clinical and experimental observations suggests that the spleen releases after irradiation an inhibitor of mitosis acting on remote organs and particularly on bone-marrow, but no clear evidence of this hypothetical factor has yet been given[1-3] In order to investigate the mechanism of this distant radiological effect, a selective splenic irradiation was carried out on lead-shielded rabbits, and certain hæmatological consequences of this procedure were studied in the blood and bone-marrow Furthermore, the isolation of an antimitotic factor from the irradiated spleen was attempted

The preliminary experiments performed on 8 pure-strain rabbits show that 48–66 h after 300 r of X-rays (dose rate 113 r /min , distance 30 cm , 180 kV , 15 m amp , filtration by 0 5 mm copper and 2 0 mm aluminium) given exclusively to the surgically exteriorized spleen, the reticulocyte blood-level drops from a mean value of 27 5 per thousand (± 3 71 = *S D* , *S E* , 0 3) to a mean value of 11 3 per thousand (± 2 75 = *S D* , *S E* , 0 5) This reticulocytopenia lasting 24–36 h points to a temporary inhibition of the erythropoiesis , this is confirmed by the fact that a decrease can be observed in bone-marrow activity 20 h after the splenic irradiation The post-irradiation mitotic index measured by a stathmokinetic method was found to be 45 per cent lower than the pre-irradiation mitotic value

A second series of 8 previously splenectomized rabbits was irradiated with the same X-ray dose on the 'splenic area' (that is, stomach and pancreas) These animals did not show any fall in reticulocyte-level or bone-marrow mitotic index This finding suggests that the transient erythropoietic inhibition occurring in the former experiments is not a consequence of some direct radio-lesion of the bone-marrow, but results from the splenic irradiation

A third set of experiments was undertaken to determine at what time after irradiation the spleen releases its hypothetical antimitotic factor For this purpose 12 rabbits were splenectomized at different intervals after irradiation of this organ and tested for erythropoietic changes It was demonstrated that only the animals the spleens of which were left in place at least 2 h after irradiation showed the typical erythropoietic inhibition, while earlier splenectomy prevented the development of this antimitotic effect

The object of the last experimental step was the isolation of an antimitotic factor from the irradiated spleen For this purpose, 12 rabbits were used, 6 as irradiated donors and 6 as test recipients As the previous results suggested that the antimitotic factor is released between 2 and 3 h after splenic irradiation, we attempted to concentrate this factor in the organ In each of the donors, the splenic veins were clamped 2 h after the 300 r. exposure, and 1 h later the blood of the congested spleen was collected with heparin After centrifugation the plasma was injected into a normal rabbit and induced in this unirradiated recipient the same erythropoietic depression previously described for the irradiated animals (bone-marrow mitotic depression and reticulocytopenia) This finding was reproduced fully in 6 experiments On the other hand, blood, collected from non-irradiated but similarly operated spleens, was shown to be devoid of any antimitotic activity This fact emphasizes the essential role of the splenic radiolesion in the production of the bone-marrow depressing factor The chemical nature of this remarkable agent is at present under investigation

Establishment and Stability of Chimerism between Two Closely Related Lines of Mice

THE Medical Research Council Radiobiology Unit at Harwell recently developed a strain of *CBA* mice containing the *T*6 marker chromosomes[3,4] They kindly sent a breeding unit to the Chester Beatty Research Institute This communication concerns a short series of experiments involving descendants of these (*CBA*/*T*6*T*6) mice and the Chester Beatty *CBA* The purpose of the experiments was, first, to define the immunological relationship between the strains , secondly, to describe the conditions under which chimerism could be established between them, thirdly, to investigate the extent and stability of this chimeric state

Skin grafting Skin grafts were exchanged between male *CBA*/*T*6*T*6 and *CBA* mice following the method of Billingham and Medawar[2] In addition, skin isografts were made to both strains of mice No intra-strain graft was rejected The mean survival times of the inter-strain grafts are shown in Table 1 The fact that rejection of interstrain grafts between *CBA* and *CBA*/*T*6*T*6 occurred in all cases proves that the two strains are genetically different but, as the rejection times were significantly (*P* = 0 001) prolonged in relation to homograft rejection times involving a known *H*-2 difference, it can be assumed that the Chester Beatty *CBA* and *CBA*/*T*6*T*6 do not differ at the *H*-2 locus The similarity between the survival times of *Ak* and *CBA*/*T*6*T*6 skin grafts on *CBA* mice confirms this It should be noted that Harwell *CBA* mice do not reject *CBA*/*T*6*T*6 skin grafts[4]

Table 1 MEAN MEDIAN SURVIVAL TIMES IN DAYS OF SKIN GRAFTS EXCHANGED BETWEEN VARIOUS STRAINS OF MICE

Donor	*H*-2	Host	*H*-2	Mean median ± S D* survival time
CBA	*k*	*CBA*/*T*6*T*6	?	22 7 ± 4 9
CBA/*T*6*T*6	?	*CBA*	*k*	23 3 ± 2 3
Ak	*k*	*CBA*	*k*	21 7 ± 2 5
*C*57*B*1	*b*	*CBA*	*k*	15 57 ± 1 3

*$n >$ 10 in each case

Injection of new-born mice 10 × 10^6 *CBA*/*T*6*T*6 adult spleen cells were injected intravenously into new-born *CBA* mice All injected mice survived and their body-weight growth curves resembled those of *CBA* mice injected with 10 × 10^6 *CBA* spleen cells No splenomegaly was observed The *CBA* mice injected with *CBA*/*T*6*T*6 spleen cells proved to be tolerant of *CBA*/*T*6*T*6 skin grafts when tested six weeks after the injection. Cytological tests, however, failed to reveal any *CBA*/*T*6*T*6 cells in the spleen, bone marrow or thymuses of the tolerant mice A total of 250 arrested metaphases were examined in four mice

These experiments emphasize the ease with which tolerance between the two strains can be acquired and show that graft-versus-host reactions between the strains, if they occur, are very limited in their effects

Radiation Chimeras Groups of thirty *CBA* mice were irradiated with 300, 500 or 700 r and then injected intravenously with 10 × 10^6 cells of *CBA*/*T*6*T*6 bone marrow Thirty and fifty days later four mice were killed in each group and cells from the bone marrow, spleen and thymus were subjected to cytological analysis following the method of Fox and Zeiss[5] The results of this analysis are given in Table 2

Table 2 NUMBERS OF HOST AND DONOR CELLS SCORED BY CYTOLOGICAL ANALYSIS IN VARIOUS GROUPS OF *CBA*/*T*6*T*6 $\longrightarrow$ *CBA* CHIMÆRAS

	Thirty days						Fifty days					
	Bone marrow		Spleen		Thymus		Bone marrow		Spleen		Thymus	
Dose	Host	Donor	Host	Donor	Host	Donor	Host	Donor	Host	Donor	Host	Donor
300	42	42	2	4	7	31	12	19	6	8	11	3
500	3	67	0	1	3	131	0	8	0	3	0	6
700	0	45	0	41	0	40	0	8	0	1	0	14

After 300 r no mice were found which did not have some dividing host cells at both thirty and fifty days, generally there was a preponderance of donor cells After 500 r three mice out of four at thirty days and none out of four at fifty days showed any host cells In no animal did these host cells account for more than 5 per cent of the total number of cells observed. No host cells were seen after 700 r

In a second experiment 850 r was the radiation dose of choice again to *CBA* mice, but in this case the number of *CBA/T6T6* bone marrow cells injected therapeutically was varied Cytological analysis was carried out on four mice from each experimental group 30, 50 and 100 days later. The results are shown in Table 3 All the cells scored except three turned out to be donor cells, a total of about fifteen hundred cells in thirty-six mice Two of the host cells were found fifty days after irradiation in animals which had been injected with 5 × 10^6 cells The remaining cell was found 100 days after irradiation in the same experimental group

Table 3 NUMBER OF CELLS SUBJECTED TO CYTOLOGICAL ANALYSIS IN VARIOUS GROUPS OF *CBA/T6T6*⟶*CBA* CHIMERAS

No of cells injected	Thirty days			Fifty days			One hundred days		
	Bone marrow	Spleen	Thymus	Bone marrow	Spleen	Thymus	Bone marrow	Spleen	Thymus
5 × 10^6	77	75	80	11	6	34	39	25	96
1 × 10^6	92	80	178	16	5	0	37	21	54
2 5 × 10^5	109	117	20	35	5	0	21	9	181

It had been hoped at the beginning of these experiments that the two strains of mice involved would prove syngeneic with respect to skin transplants This would have facilitated a study of chimerism in as near syngeneic a strain combination as is compatible with the presence of a chromosome marker

It is particularly important to be sure that syngeneic chimeras are, in fact, functionally chimeric with very few or no host cells contributing to hæmatopoiesis, otherwise the use of radiation animals as tests for viability of, say, frozen cells[1] is fraught with interpretative difficulty Fortunately, Ford and Micklem[4] recently found that four syngeneic chimeras out of 16 showed some host cells but that in no case did these cells account for more than 5 per cent of the dividing cells discovered In the present work few host cells were found and altogether it appears clear that minor genetic differences are probably of little importance in impeding the establishment of chimerism after irradiation, and that mice irradiated and then injected with syngeneic or near syngeneic bone marrow cells are for practical purposes chimeric It is, in any event, impossible to deny that host cells may be present, it is only possible to be sure that they do not divide with appreciable frequency and therefore probably do not make a significant contribution to hæmatopoiesis

We thank Prof P C Koller of the Chester Beatty Research Institute for his advice and encouragement This work was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research · Royal Cancer Hospital) from the Medical Research Council, the British Empire Cancer Campaign, the Anna Fuller Fund, the National Cancer Institute of the National Institutes of Health, U S Public Health Service, and the International Atomic Energy Agency (Contract No 103 1/US)

BIOLOGY

Anaerobic Life in a Tropical Crater Lake

THERE are very few records of animals other than Protozoa found living in oxygen-free water for which there seems to be good evidence of prolonged and active anaerobic life[1,2] In many cases there is the possibility of periodic visits to oxygenated water and in others the oxygen demand is lowered by the reduction or even complete cessation of activity Certain planktonic crustacea especially *Cyclops* spp and some insect larvæ and molluscs have, however, been found living actively in the oxygen-free water and mud at the bottom of temperate eutrophic lakes during summer stratification, and the evidence for anærobiosis lasting for a few months is convincing.

In the tropics the temperature régime is such that more or less permanent stratification and deoxygenation of lakes is rather common, Lake Tanganyika being the supreme example There have been, so far as I know, no records of planktonic animals from the anoxic lower water of such lakes and in Lake Tanganyika they are reported to be completely absent[3]

Ruttner[4], who had much experience of lakes both in Europe and in the tropics of Java and Sumatra, expressed the opinion that, owing to the temperature which may be almost 20° C above that at the bottom of temperate lakes, the rate of metabolism in tropical lakes might be high enough to prohibit adaptation to low oxygen-levels.

It is, therefore, of interest to record some observations on a small volcanic crater lake, L Nkugute, in Western Uganda which is about 1 000 m in diameter and 58 m deep and is very well protected from wind disturbance by the crater wall and surrounding hills These circumstances and the tropical temperature régime ensure a permanent stratification, and from about 15 m to the bottom the water is out of circulation and devoid of oxygen, and the lake is consequently very unproductive

By means of a vertically hauled closing plankton-net and later by pumping up and filtering 200-litre samples, the copepod *Thermocyclops schuurmanni*, the rotifers *Horaella brehmi* and *Keratella tropica*, and a ciliate protozoan were taken as close to the bottom as it was possible to collect, that is to say with some 40 m of oxygen-free water above them, and where there was a constant temperature of 22° C

T schuurmanni is particularly interesting because the adult egg-bearing females were confined to the upper oxygenated water, where all stages of development were also to be found, but the lowest samples contained only nauplius larvæ and young copepods

The evidence therefore suggests that eggs are produced only in the upper oxygenated water and that some of them are shed and fall to the bottom where the first stages of development proceed in the absence of oxygen Whether the young copepods then return to the surface to mature and reproduce is not yet known Preliminary experiments indicate that the adults cannot live for more than a few hours without oxygen and one is led to the conclusion that the respiratory metabolism changes radically during development

Redox potentials in the lower water and mud are considerably higher than most of those recorded for temperate eutrophic lakes at the height of summer stratification For example, Mortimer[5] recorded zero potentials (E_h) just above the mud in Esthwaite Water in September The corresponding potential in Lake Nkugute was +180 to +220 mV This is perhaps not unexpected under conditions of permanent stratification where, in the absence of an overturn, readily reducible substances would be more nearly exhausted and only small quantities would be available as particles descending from the unproductive surface water It would seem that lack of oxygen is less of a barrier than a low redox potential usually associated with the accumulation of toxic substances such as hydrogen sulphide, which in the bottom water of Lake Nkugute was in extremely low concentration and only just detectable by smell but which, from all accounts, is abundant below 150 m in Lake Tanganyika (max depth, 1,400 m)

The activities of organisms such as *Thermocyclops schuurmanni* would cause at least a small chemical circulation between upper and lower water under conditions of stable stratification

Further observations and experiments are obviously needed, but preliminary work has shown a similar situation in Lake Bunyoni (about 50 m deep), which is a narrow-flooded branching river valley blocked by a lava flow

I thank Drs J P Harding and J D Green for identifying the copepod and rotifers

A Comparison of the Sensitivity to Storage at 37° C in Tyrode Solution of Immunologically Competent Cells and of Myeloid Cells

IN an earlier investigation[1,2], we have demonstrated that storage for 2 h at 37° C in Tyrode solution causes hæmopoietic cells to lose a considerable part of their capacity to induce, through a graft reaction to the host, secondary syndromes in the irradiated allogenic recipient, whereas their capacity to restore myeloid tissue is not noticeably affected

Two different explanations of this phenomenon are possible: (*a*) either the immunologically competent cells are more sensitive to this type of storage than the immature myeloid cells, (*b*) or the sensitivities of these two types of cells to this form of aggression are the same and the difference of the effects on the graft reaction to the host and the capacity to restore myeloid tissue is due to the fact that the relations of these two phenomena to the numbers of cells that cause them are regulated by different laws

In order to test these two hypotheses it is necessary to carry out a quantitative determination of the respective relations between the frequency of death from graft reaction to the host and the number of lymphoid cells on one hand and between the myeloid restoration and the number of myeloid cells on the other

Then it will be possible to compare the effect of storage for 2 h at 37° C in Tyrode solution on the graft reaction to the host by the number of lymphoid cells affected, and its effect on the myeloid restoration by the number of the myeloid cells affected

Material and methods (*a*) 240 F_1 mice of the strain $DBA/2 \times C_{57}Bl/6$, three months old, were exposed to whole-body irradiation with 500 rad (200 kV, 12 m amp, 50 cm distance, 0 5 aluminium, 0 5 copper) Immediately after the irradiation they received intravenous injections of 10^7 non-preserved $C_{57}Bl/6$ medullary cells The animals were divided non-selectively into 2 groups, *A* and *B*, of 120 animals each

The mice of group *A* were divided over 6 sub-groups of 20 animals each and these groups were given intravenous injections of non-preserved $C_{57}Bl/6$ lymph-node cells, of 4×10^7 cells, $2\ 5 \times 10^7$ cells, 10^7 cells, 5×10^6 cells, 10^6 and 10^5 cells, respectively

The mice of group *B* were also divided over 6 subgroups of 20 animals each, which were treated intravenously with 4×10^7, $2\ 5 \times 10^7$, 10^7, 5×10^6, 10^6 and 10^5 C_{57} $Bl/6$ lymph-node cells that had been stored for 2 h at 37° in Tyrode solution The conditions of the storage were as follows a suspension of 2×10^5 cells/mm³ of Tyrode solution was prepared, 3–4 ml of this suspension was placed in glass tubes of 20 ml. and kept for 2 h at 37° C in continuous rotation

(*b*) 160 F_1 mice of strain $DBA/2 \times C_{57}Bl/6$ were irradiated with a dose of 950 rads and divided at random over 2 sub-groups, *A* and *B*, of 80 animals each Group *A* was subdivided into 4 groups of 20 animals treated intravenously with 10^6, 10^5, 10^4 and 10^3 fresh isogenic medullary cells, respectively

Group *B* was also divided into 4 sub-groups of 20 animals each, which were treated intravenously with 10^6, 10^5, 10^4 and 10^3 isogenic medullary cells, respectively, that had been stored for 2 h at 37° C under the conditions mentioned here

Lymphoid cells and graft reaction to the host The results obtained are listed in Table 1 Calculation by the probits method of the number of fresh lymph-node cells required to cause 50 per cent deaths by the graft reaction to the host gives a number of about 1,070,000 cells in group *A*

This determination is impossible in group *B*, since the number of surviving animals in the most affected subgroup was 16 of 20; it is nevertheless certain that the number of preserved lymph-node cells required to bring about 50 per cent deaths is larger than the largest number of preserved lymph-node cells injected, which amounted to 40,000,000

Table 1 Graft-to-host reaction provoked by fresh C_{57} $Bl/6$ lymph-node cells (group *A*) and by $C_{57}Bl/6$ lymph-node cells stored for 2 h at 37° C (group *B*) in F_1 ($DBA/2 \times C_{57}Bl/6$) hosts irradiated with a dose of 500 rads and treated with 10^7 fresh $C_{57}Bl/6$ medullary cells

Group *A*	No of test animals	Animals surviving after the hundredth day
4×10^7 fresh lymph-node cells	20	0
$2\ 5 \times 10^7$ fresh lymph-node cells	20	0
10^7 fresh lymph-node cells	20	4
5×10^6 fresh lymph-node cells	20	6
10^6 fresh lymph-node cells	20	8
10^5 fresh lymph-node cells	20	14
Group *B*		
4×10^7 preserved lymph-node cells	20	19
$2\ 5 \times 10^7$ preserved lymph-node cells	20	20
10^7 preserved lymph-node cells	20	16
5×10^6 preserved lymph-node cells	20	16
10^6 preserved lymph-node cells	20	18
10^5 preserved lymph-node cells	20	17

Medullary cells and capacity to restore myeloid tissue The results of this are listed in Table 2 The criterion of the myeloid restoration was survival on the thirtieth day Calculation by the probits method of the number of medullary cells necessary to bring about myeloid restoration in 50 per cent of the animals gave about 216,000 ($170,000 < ED_{50} < 275,000$ for $P = 0\ 05$) for the fresh isogenic medullary cells and approximately 214,000 ($153,000 < ED_{50} < 298,000$ for $P = 0\ 05$) for the medullary cells that had been stored for 2 h at 37° C

Table 2 Myeloid restoration by isogenic medullary cells, either fresh (group *A*) or stored for 2 h at 37° C (group *B*) in F_1 ($DBA/2 \times C_{57}Bl/6$) hosts irradiated with a dose of 950 rads

Group *A*	No of test animals	Animals dead before the thirtieth day
10^6 fresh medullary cells	20	7
10^5 fresh medullary cells	20	14
10^4 fresh medullary cells	20	13
10^3 fresh medullary cells	20	20
Group *B*		
10^6 preserved medullary cells	20	7
10^5 preserved medullary cells	20	13
10^4 preserved medullary cells	20	17
10^3 preserved medullary cells	20	18

We may conclude that the results obtained answer the question investigated (*a*) In a hæmopoietic graft, preservation for 2 h at 37° C in Tyrode solution does not notably influence the number of cells required to bring about myeloid restoration in an irradiated recipient; in order to obtain the same biological result, namely, 50 per cent restoration, which is the result for which the determination of the required number of cells can be the most accurate, there must not be more preserved than fresh medullary cells. (*b*) On the other hand, this preservation has a considerable influence on the immunologically competent cells which, when immunized against a semi-allogenic host, are killed through a graft-to-host reaction: 1,000,000 fresh lymph-node cells kill 50 per cent of the animals, but of the cells that have been stored for 2 h at 37° C in Tyrode solution 40,000,000 are not enough to bring about the same effect; accordingly it may be concluded that this preservation affects more than 97·5 per cent of those cells that are capable of evoking a graft-to-host reaction.

Frontal Foramina and Tripodes of the Characin *Crenuchus*

Gery[1] has recently described a pair of foramina in the frontal bones of *Crenuchus spilurus* Günther. These foramina underlie the posterior margin of a pad of fatty tissue which covers the anterior part of the skull roof. Gery found by dissection that they contained structures which seemed to be connected to the brain. His specimens were not well enough preserved for histological examination.

I possess two well-preserved specimens of the same species. I have cut serial transverse and horizontal sections of their heads, and stained them with Mallory's triple stain. Each frontal foramen is filled by a plug of tightly packed, tangled collagen fibres, penetrated by a few small blood vessels (Fig. 1). The collagen fibres of the plug are continuous with those of the fatty pad, of the periosteum of the frontals, and of the interesting structure shown in Fig. 2. This structure lies posterior to the plug, within the cranial cavity. It includes blood vessels, collagen fibres, and a group of elongate vesicles, partially filled by a lightly staining homogenous substance. It is served by a substantial branch of the superior ophthalmic nerve.

It seems probable that this is a sense organ. The vesicles (reminiscent of ampullæ of Lorenzini, though they have no external openings) and the innervation by the superior ophthalmic nerve suggest derivation from lateral line organs. If it is an exteroceptor, the stimuli to which it is sensitive must be able to affect it through the collagenous pad.

Gery[1] also discussed the tripodes of *Crenuchus*. He stated that they are not of the type found in other characins. I have cut horizontal sections of the Weberian apparatus of one of my specimens of *Crenuchus*, and am unable to confirm this. The anterior edges of the tripodes (Fig. 3) are formed by bony lamellæ which are fused to the third centrum but not, apparently, to the more posterior bony parts of the tripodes. This structure is identical with that of the tripodes of *Astyanax* (typical of Characinoidei) and contrasts strongly with that of *Carassius* (typical of Cyprinoidei) which have been illustrated elsewhere[2]. In Cyprinoidei there are no separate bony lamellæ, and the tripodes are attached to the centrum by the cartilage which fills them.

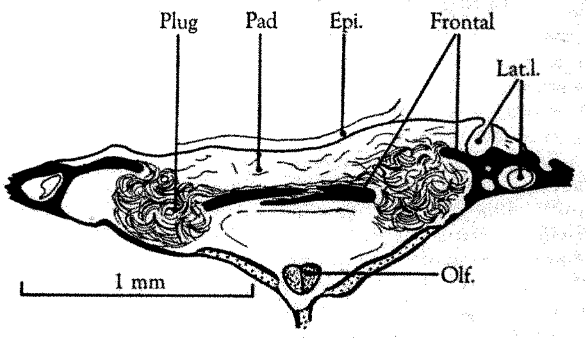

Fig. 1. Camera lucida drawing of part of a transverse section of *Crenuchus* showing the frontal foramina, collagenous plugs and fatty pad. *Epi.*, epidermis (damaged); *Lat. l.*, lateral line canal and pore; *Olf.*, olfactory tract

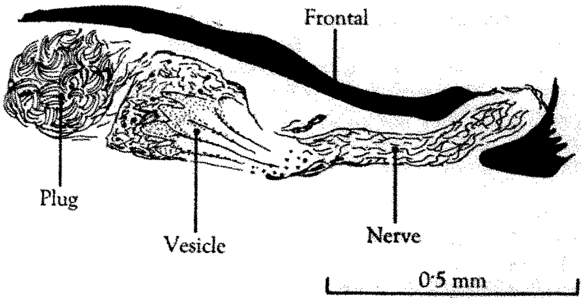

Fig. 2. Camera lucida drawing of part of a horizontal section of *Crenuchus* showing a collagenous plug, the vesiculate structure associated with it, and the nerve. The top of the figure is lateral and the left anterior

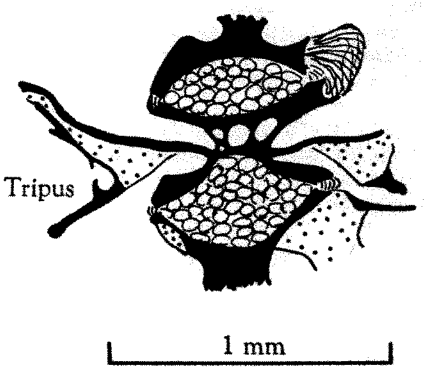

Fig. 3. Camera lucida drawing of a horizontal section through the third centrum and tripodes of *Crenuchus*. The top of the figure is anterior. Bone is shown black and cartilage is stippled

Gery[1] also suggests that the tripodes of Erythrininae may lack the bony lamella. The tripodes can, however, be seen to be attached to the centrum by a bony lamella, and seem to be of entirely normal characin type, in my sections of *Erythrinus erythrinus* (Bloch and Schneider).

Weitzman's[3] definition of the Characinoidei in terms of the structure of the tripodes, to which Gery[1] refers, is faulty in that, of the Cypriniformes, it excludes only the Cyprinoidei. The tripodes of Gymnotoidei[2] and Siluroidei[4,5] are attached to the centrum by bony lamellæ. In Siluroidei, however, the lamella is fused to the main body of the tripus.

The specimens described here were collected by the Cambridge Expedition to British Guiana, 1960, of which I was a member.

Temperatures in Heather Burning

Recently the subject of heather burning has come under more critical review. Of particular interest is the measurement of the temperatures recorded in fires and the effect of this heat on the establishment of new growth and the long-term effects on the fertility of the soil.

Whittaker[1] recorded temperatures occurring in heather burning by means of 'Thermocolours', heat-sensitive paints, and in later experiments[2], organic compounds of specific melting points. Her results show that the maximum temperatures experienced in heather burning are of the order of 840° C and that the temperatures most frequently recorded are between 300° C and 500° C at ground-level. It is suggested[1] that these temperatures are maintained for periods of less than 2·5 min.

The time-temperature complex, that is, the time during which fixed temperatures are maintained, is important from three different aspects. The regeneration of new growth both from seedlings and from the base of the old stem depends on this. In addition, work in this laboratory has shown that the losses of nitrogen in smoke depend on the period for which temperatures are maintained; and has demonstrated the varying solubility of nutrients in plant ash derived from heather leaves burnt under various temperature conditions.

Whittaker suggested the use of thermocouples as an accurate method for the measurement of fire temperatures. The major difficulty with this type of measurement is the recording of data under field conditions with no source of electricity to power bulky recorders and amplifying systems. Mervyn Instruments, Ltd., have recently produced a portable transistorized recorder. This makes possible the recording of temperatures over any given range with the appropriate thermocouples.

Recordings were made over the range 0°–1,000° C. The recording equipment consisted of 5 thermocouple units connected to a manual switch, which in turn was connected to the recording instrument. Each thermocouple unit was made up from 3 ft. 'Insuglass Chromel Alumel' connected to compensating wire by copper points buried in the ground. The overall distance from the thermocouple point to the recorder was 40 ft.

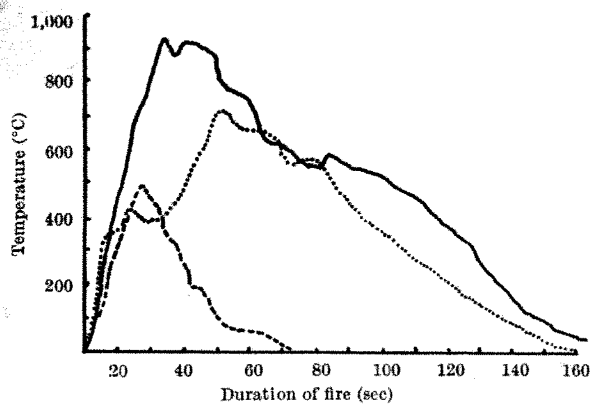

Fig. 1. Three chart records for vegetation of different ages. ——, 35 yr. old; · · · ·, 20 yr. old; – – –, 10 yr. old

The results presented here are the result of work carried out in April 1963 on fires in Glen Clova, Angus. Fig. 1 shows the typical recording for heather of different ages, showing clearly the general increase in temperature of fires with increase in age of vegetation. All the readings are for temperatures recorded in the leafy parts of the plants. The maximum temperature recorded was 940° C and the average maximum from 35 fires was 670° C. These temperatures are higher than those recorded by Whittaker[1] under similar conditions. As the conditions last spring were particularly wet, it may well be that these temperatures may be exceeded when burning old heather.

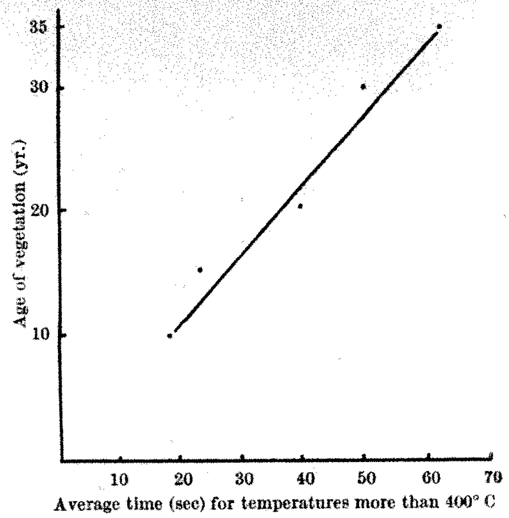

Fig. 2

At temperatures above 400° C there are significant losses of nitrogen in smoke, and thus it is important to estimate the time for which temperatures more than 400° C are maintained. Fig. 2 shows the average time for which temperatures more than 400° C are maintained in the fires studied and its dependence on the age of the vegetation. Whittaker[2] has used similar time periods for the study of heat tolerance of heather seeds. These results have confirmed Whittaker's predictions.

A Mould Inhibitor in Soybeans

Seeds of *Glycine max* Merr. (soybean) contain several biologically active materials, including saponins and trypsin inhibitors[1]. However, in a recent review of the antimicrobial activity of vascular plants[2], no mention is made of the occurrence of antimicrobial compounds in soybeans. We are reporting the presence of a factor(s) that inhibits the mould growth of *Rhizopus* sp. (provisionally identified as *R. oligosporus* Saito), which is utilized in the fermentation of soybeans to make the Indonesian food tempeh[3].

In making tempeh[4], soybeans are soaked in water for several hours, and then this water is discarded at the time the soybean hulls are removed. The dehulled beans are then boiled for 30 min in sufficient fresh water to cover the beans during the entire boiling process. This boiled water extract is discarded prior to inoculation and fermentation with *Rhizopus*. Under the fermentation conditions, the mould grows rapidly and in less than 24 h completely covers the soybeans. The soybeans are held together by the hyphæ of the mould and little sporulation occurs except at the edges of the moulded soybean mass if the fermentation is done in Petri dishes. In our investigations of tempeh, we found that an excellent product could be produced by using full-fat soybean grits. However, when the foregoing procedure of discarding the soaking and cooking water was used, it was discovered that considerable soybean material was discarded with the soaking and cooking water. For example, 1,200 g of dry, full-fat soybean grits were placed in beakers, covered with tap water and allowed to take up water, washed in 1,000 ml. of tap water, again covered with tap water and boiled for 30 min and drained. After these uninoculated grits were freeze-dried, the dried mass weighed 845 g, a loss of 355 g. The loss in weight was due to the presence of small suspended particles as well as dissolved material in the liquor that was discarded.

To reduce the processing loss, we modified the procedure for making tempeh, by two methods: the first method was to retain the soaking water and then add sufficient water so that the beans could be boiled for 30 min. At the end of this time, practically all the water had evaporated, leaving the soybeans moist and sterile. The second method was to soak the beans in sufficient water so that the grits were thoroughly moistened but practically no excess water was left. These moist grits were then steamed for 30 min for sterilization. In each method, no water was discarded in order to reduce the processing loss. When soybeans were prepared for fermentation by either of the above methods, the product was quite inferior to normal tempeh. For example, the following experiment was typical of a number we performed. Full-fat grits made from Hawkeye soybeans were given the following treatments and then each product was divided equally into inoculated and uninoculated parts.

Treatment 1. Tap water was added at the rate of 175 ml./125 g of grits, which were allowed to stand overnight. Next, they were autoclaved for 30 min at 5-lb. pressure, then cooled, and half the sample was inoculated with spores of strain N.R.R.L. 2710 *R. oligosporus* and packed in Petri dishes. The remaining uninoculated half of the sample was stored in a refrigerator.

Treatment 2. Tap water was added at the rate of 300 ml./125 g of grits, which were allowed to stand overnight. They were boiled to evaporate excess water but were left still moist. The sample was divided and handled as in treatment 1.

Treatment 3. Grits were soaked overnight in sufficient tap water to leave a small amount of water above the grits at the end of the soaking period. The excess water was discarded, new water was added, the grits were boiled for 30 min, and the water was again discarded. The grits were cooled and part inoculated as in treatment 1. This method was essentially the Indonesian one, except grits were used instead of whole soybeans.

Treatment 4. Grits were washed with tap water but not soaked, then fresh tap water was added in excess, the grits were boiled for 30 min and this water was discarded. The grits were then handled as in treatment 1.

Each part that had been inoculated was allowed to ferment at 31° C for approximately 24 h.

The finished fermented tempeh made from treatments 1 and 2 showed reduced growth and poor fermentation, had a disagreeable odour, was greyish-white, had reduced development of mycelium and had sporangia scattered through the cake. On the other hand, the fermented products of treatments 3 and 4 were white cakes with abundant mycelium, sporulation restricted to the edges and a pleasant odour. When the fermented soybeans were sliced and cooked in vegetable oil, the tempeh from 1 and 2 had a dark reddish-brown colour, poor flavour and odour described by some as like that of burnt rancid bacon. Those from treatments 3 and 4 were normal tempeh with a bright light colour and excellent flavour. The four samples of uninoculated grits were also cooked, and those from treatments 1 and 2 were darker in colour than those from 3 and 4. However, the flavour of the unfermented grits of 1 and 2 were not obviously disagreeable; whether or not grits were soaked overnight made very little difference in making good tempeh. Washing also removed some of the colour from the beans. However, if the water from soaking and cooking was not discarded, poor tempeh resulted.

One may conclude that a factor or factors present in the soybean grits needs to be washed out to get a good fermentation. The inhibitory factor must be heat-stable and water-soluble. The inhibition of mould development offered the possibility of using *R. oligosporus* as an assay organism for the isolation of the factor which might be important not only in tempeh but also in soybean milk, soybean flour and other soybean products with respect to their food value. Whether the factor has an effect on higher organisms is not known. When whole soybeans instead of grits were prepared and when no water was discarded in the process, a poor fermentation resulted, as described here. The actual amount of substrate metabolized indicated a considerable reduction over that metabolized in making normal tempeh. This factor is present not only in the cultivated variety Hawkeye, but also in 15 other varieties examined from the United States and Japan in varying amounts. Of the varieties tested, Norchief appeared to have more of the factor present than any of the others tested, but made excellent tempeh when the factor was removed.

In making tempeh, the cooked soybeans are spread out to cool and to dry the surface of the beans before inoculation with *Rhizopus*. This permits some bacterial contamination to occur from the air. The possibility exists, therefore, that growth-promoting substances for bacteria might remain in the soybeans if the water is not discarded, thereby promoting bacterial growth which in turn restricts the growth of *Rhizopus*. Accordingly, tempeh was prepared deliberately to give poor tempeh, and at the time of inoculation varying levels of tetracycline from 5 to 25 μg/g were added to the beans. At the end of the fermentation, all the tempeh was uniformly poor. When the tempeh was examined for bacteria by streaking out some of the material on nutrient agar, no bacteria could be detected in the tempeh in which 20 and 25 μg/g of tetracycline had been added. Their absence would seem to eliminate the possibility of bacteria interfering with the development of the mould.

A Glass Micro-bead System for the Investigation of Soil Micro-organisms

INVESTIGATION of the microbial flora of soils is greatly complicated by the physical complexity of soil as a medium. There are, of course, many biochemical and respirometric studies of the activity of micro-organisms in soil which treat it as though it is a homogeneous tissue. In fact, however, the system lacks continuity and consists of innumerable semi-independent micro-habitats. Soil is a porous medium with large internal surface. The distribution, retention or movement of water in soil depends on capillary and surface forces, and is of great moment in determining the distribution of micro-organisms and the characteristics of the micro-habitats that can be colonized if substrate is present. Most natural soils are texturally heterogeneous with the result that the behaviour of micro-organisms in them is the summation of many different situations.

In attempts to obtain a clearer understanding of factors affecting the distribution of bacteria and fungi in soils we have made use of a growth medium comprising glass micro-beads of uniform size. With such a system it is possible either to calculate, or to determine directly, such properties as internal surface, pore size, porosity, moisture tension relationships and water distribution, as some soil physicists have shown[1,2]. If soluble nutrients are supplied in the water, microbial growth and activity can be followed by a diversity of appropriate procedures.

Although micro-beads are available in a wide range of sizes (Microbeads, Inc., Jackson, Mississippi), we have carried out orienting experiments with two sizes only—37μ diameter and 149μ diameter (referred to in this communication as small and large beads respectively). Prior to their use in microbiological work the beads, as supplied by the manufacturer, require rigorous cleaning with acid followed by rinsing and decantation with distilled water to remove surface alkali. Washing must be continued until the *p*H of water in equilibrium with the beads is close to that of the distilled water used. Table 1 gives observations of some physical properties of the two sizes of micro-beads used. It will be noted that there is a four-fold difference in internal surface between the large and the small beads, and that at 100-cm tension the small beads retain 40 per cent more water than the large.

For microbiological studies a constant aeration procedure has been used in which each micro-bead system, contained in 8-oz. glass tumblers, is ventilated with moist, sterile air free from carbon dioxide at a controlled rate of flow of 9 l./h. The bead systems are initially wetted with nutrient liquid into which is incorporated the inoculum of the organism or organisms being examined. Measurement of the amount of carbon dioxide evolved by the microbial population of the bead medium is made by passing the effluent air stream into 0·75 N sodium hydroxide. Carbonate formed is then precipitated by addition of 25 per cent barium chloride and excess base determined with standard hydrochloric acid in an automatic titrator.

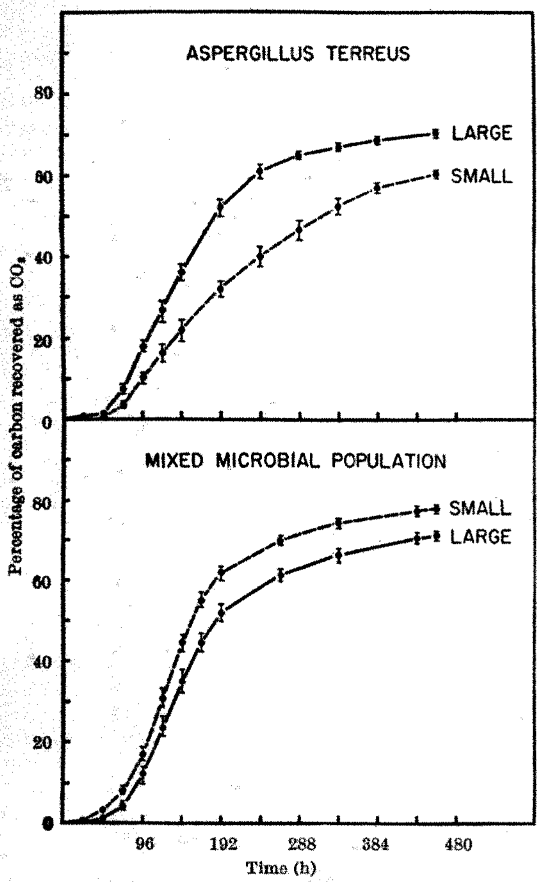

Fig. 1. Percentage of glucose carbon recovered as carbon dioxide from glass micro-bead media inoculated with (upper curves) *Aspergillus terreus* or (lower curves) a mixed soil microbial population. Systems consisted of 100 g of small beads (37μ mean diameter) or large beads (149μ mean diameter) plus 2 g glucose at 100 cm moisture tension. Each point is the mean of five replicates; limits of variation shown by vertical lines

Table 1. PHYSICAL PROPERTIES OF TWO SIZES OF MICRO-BEADS

	Large beads	Small beads
Mean diameter (μ)	149	37
Total surface (open pack) (cm²/g)	140	564
Bulk density (g/c.c.)	1·52	1·45
Particle density (g/c.c.)	2·50	2·50
Pore space (percentage of total volume)	39	42
Moisture retention at 100 cm tension (per cent, oven dry weight)	17·5	24·5
Theoretical values assuming perfect spheres		
Bulk density (g/c.c.)	Close pack	1·85
	Open pack	1·35
Pore space (percentage of total volume)	Close pack	26·0
	Open pack	47·6

At present we are following the rate of glucose degradation by various micro-organisms and mixed populations at the same moisture tension in systems comprised of small or large beads. Developmental changes in the numbers or distribution of the organisms are followed by sampling, plating and by direct and indirect examination of the bead mass. In this work 100-g samples of micro-beads have been initially wetted with nutrient containing 2 per cent glucose, with determinations of evolution of carbon dioxide and other changes at intervals. Fig. 1 gives information on the percentage of glucose carbon recovered as carbon dioxide over a 450-h period from bead systems inoculated with *Aspergillus terreus* compared to systems inoculated with a mixed microbial population of unknown constitution, derived from a soil suspension. The behaviour of replicate units in such experiments has been remarkably uniform. In experiments so far, we have observed that the micro-bead size by affecting the microbial environment clearly influences microbial distribution and activity.

Calculations of microbial activity on a known substrate (using evolution of carbon dioxide as the index of activity) can be related to other observations, and the effects of physical changes in the environment can be followed.

It appears that the use of micro-bead media has considerable potential for studying the growth and activity of soil micro-organisms, allowing, as it does, the construction of closely defined solid–liquid–gas systems, akin to soils, into which a wide range of energy and nutrient sources can be incorporated. The energy source may be soluble and therefore continuous, or insoluble and discontinuous. Micro-organisms may be examined in pure cultures or in known combinations. Water relationships and internal surface may be varied by the selection of appropriately sized beads or the incorporation of a homogeneous clay. Changes in gas diffusion rates accompanying colonization of the water film can be followed experimentally in such systems. The micro-bead media may also be used as a rooting material for seedlings of higher plants and thus applied in studies on root-microbe interactions or rhizosphere ecology.

Branch, Stem and Collar Rot of Apple caused by *Phytophthora* Species of the '*cactorum* Group'

BARK rot of apple trees, caused by *Phytophthora cactorum* (Leb. and Cohn) Schroeter, has been reported from most of the world's major apple-growing areas. Outbreaks of this soil-borne disease are often epidemic in character and may result in the complete bark-girdling and death of many trees.

Both *P. cactorum* and the closely related *P. syringae* Kleb. have been shown to be pathogenic to apple bark[1-3]; but a recent report from Holland[4] is the only published record of crown or collar rot of apple caused by *P. syringae*. This fungus has been isolated from naturally infected trees in Essex, Kent and Suffolk, and it now appears possible that *P. syringae* bark rot may be more widespread in England than that caused by *P. cactorum*, which in Europe and New Zealand primarily affects the variety Cox's Orange Pippin. *P. syringae* has been isolated from mature trees of Cox's Orange Pippin, Worcester Pearmain, Laxton's Fortune and Superb, and Miller's Seedling, and from one-year-old trees of Cox, Worcester and Tydeman's Early Worcester. *P. syringae* thus appears to be capable of attacking a wider range of varieties under orchard conditions than *P. cactorum*.

Disease outbreaks in 20–30-year old trees tend, like those caused by *P. cactorum*, to be widespread in the first instance. Trees are rarely completely girdled before external symptoms are visible; bark lesions frequently extend up the trunk in narrow tongues seldom spreading more than one-third around it.

Inoculation investigations indicate that susceptibility to both species varies markedly with the stage of host development, and that *P. syringae* can cause extensive damage at low temperatures in February and March when inoculations with *P. cactorum* have frequently failed. Resistance to both pathogens is lowest during and for some weeks following budburst. Extension of established *P. cactorum* lesions may continue in the subsequent summer and winter, whereas *P. syringae* lesions are often arrested in the summer; subsequent bark splitting and callus formation around the lesion may stop further extension and trees then recover without treatment.

Both species are difficult to isolate from rotted bark, especially *P. syringae* which grows and produces sporing structures very slowly. In the most successful isolation method, 5-mm cubes of bark from the margins of active lesions were irrigated in running tap water for 24–48 h and then incubated at laboratory temperature in a shallow layer of still water for a further 12 h. Under a wide-field binocular microscope *P. cactorum* was detected by the presence of the characteristic, coarse, irregular hyphæ, frequently bearing sporangia. The hyphæ of *P. syringae* were less readily seen for they protruded only a short distance from the bark blocks and rarely formed sporangia. Suspect hyphæ were inserted into apple fruits on which firm, brown, somewhat irregular lesions developed after 5–10 days and isolations from the margins of these on to cornmeal agar generally yielded pure cultures of the pathogen. Incubation temperatures should not exceed 20° C. Most isolates of *P. cactorum* readily produce sporangia and oospores, but *P. syringae* does so very sparsely and may fail to form oospores except in old cultures. Many *P. syringae* isolates form characteristic complex chains of hyphal swellings. All isolates of *P. syringae* have failed to grow at 25° C, the optimum temperature for *P. cactorum*.

Investigations of *Phytophthora* spp. in orchard soils have revealed marked differences in their seasonal activity, and also that the third member of the '*cactorum* group', *P. citricola* Sawada (syn. *P. cactorum* var. *applanata* Chester), is widespread and abundant. This species causes black root rot of hops[5], and as certain isolates have been shown by the authors and Smith[6] to be very mildly pathogenic to apple bark, all species of the '*cactorum* group' may be implicated to varying degrees in collar and crown rot diseases of apple. The Malling and Malling–Merton apple rootstocks have been tested[2] for resistance to *P. cactorum*; tests with *P. syringae* are in progress together with comparative studies of the resistance of apple scion varieties to both pathogens.

Apple Scald Induction by Anaerobiosis

SCALD is a physiological disorder which seriously affects the appearance and utility of the apple fruit. It initially appears during, or following, cold storage as a brown discoloration of the epidermis of the green-coloured portion of the fruit. With advancement, it affects the anthocyanin-bearing epidermis, the hypodermis and the adjacent cortex. Extensive investigations over the past 60 years have provided several theories[1-7]; but relatively little knowledge pertaining to the cause of scald. Several means of control have been devised[2,8,9]. As early as 1903[1], it was observed that scald formation was influenced by the availability of oxygen to the fruit. Our results now provide a basis for defining the ætiology of apple scald in terms of basic cause and effect components, anaerobiosis and aerobiosis.

Fruits of the McIntosh and Red Rome varieties of apple (*Malus sylvestris*, Miller) stored for 3 months at 0°–2° C were used for this investigation. Scald-free apples were placed in chambers at 20° C through which either air or nitrogen gas was supplied for various durations at a rate to provide two atmosphere changes per hour. The fruits were examined for scald at the termination of nitrogen

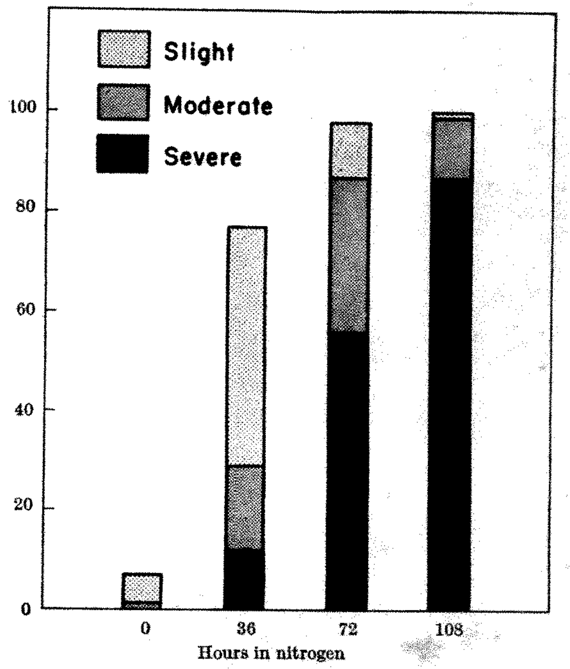

Fig. 1. Percentage and severity of scald on McIntosh apples following anaerobiosis treatments after 7 days in air at 20° C

treatments and subsequent periods in air at the same temperature. McIntosh fruits exposed to nitrogen for 36, 72 or 108 h were free of scald on removal, but afterwards developed scald on exposure to air (Fig. 1). The incidence and severity of scald were directly proportional to the duration of anaerobiosis. The rate of scald development in air following nitrogen induction was considerably lower at 0° C than at 20° C. This dependence on temperature clearly links the developmental phase of this disorder with aerobic respiration. Thus, scald was induced anaerobically and developed aerobically.

To relate physiologically the symptoms of induced and naturally occurring scald, Red Rome apples, which had been treated prior to storage with diphenylamine (DPA), a scald inhibitor[8], were compared with a comparable non-DPA-treated sample. One-half of each fruit sample received a nitrogen atmosphere for 108 h. The other half was maintained in air for the same period. All fruits were evaluated for scald after an additional 36 h in air. Diphenylamine significantly inhibited or retarded scald development on apples exposed to 0–108 h of nitrogen (Table 1). The scald-inhibiting properties of DPA counteracted or reduced the inductive influence of anaerobiosis on scald development aerobically. Therefore, it is likely that naturally occurring scald and anaerobically induced scald are the same disorder.

Table 1. INCIDENCE OF SCALDED RED ROME APPLES 36 H AFTER 108 H OF AEROBIC OR ANAEROBIC ATMOSPHERES AS AFFECTED BY PRE-TREATMENT WITH 2,000 P.P.M. DIPHENYLAMINE (DPA)

Atmosphere	Mean per cent scalded fruits*	
	Non-treated	Treated
Aerobic (air)	9·4*a*	0*a*
Anaerobic (N_2)	34·4*b*	7·3*a*

* Means followed by dissimilar subscripts differ at odds of 19 : 1.

Apparently, apple scald is composed of two physiologically distinct phases, one of anaerobic induction and one of aerobic development. This pattern is compatible with most theories on development and control of this disorder. The mechanism of scald induction and development is under investigation.

Reciprocal Effects of Insect and Plant-growth Substances

INJECTION of homogenates of active prothoracic glands into fourth instar locust larvæ, a day after moulting, causes them to moult again prematurely. The instar is shortened by about 12–18 h (Fig. 1). The active agent appears to be an ecdysone (which we have named ecdysone-λ). Injection of those fractions of extracts of whole locusts that contain ecdysone-λ have a similar effect. The plant growth hormone gibberellic acid likewise shortens the instar when injected at the appropriate time into larvæ of both *Locusta migratoria migratorioides* (R. and F.) and *Schistocerca gregaria* (Forskål) (Fig. 1).

Blood taken from locusts about to moult and ecdysone from *Bombyx* (ecdysone-α) have specific effects on the nervous system of locusts that results in reduced locomotory activity[1]. Fresh homogenates of active prothoracic glands of locusts, solutions of gibberellic acid and locust extracts containing ecdysone-λ all have a similar effect.

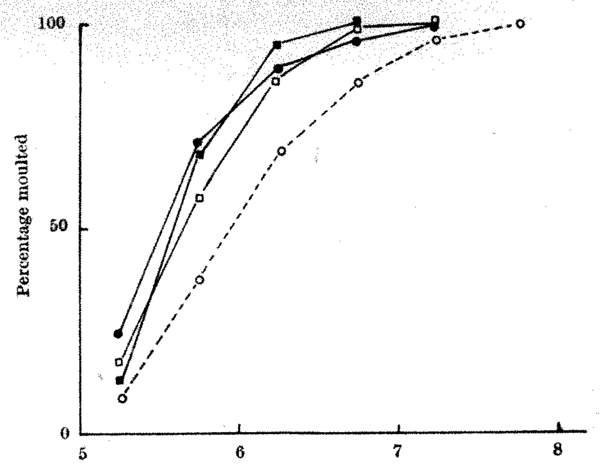

Fig. 1. Cumulative percentage of locusts moulting in successive periods of 12 h after injection of: ○ -- ○, solvent alone; ■, fresh homogenate of prothoracic gland, one gland per animal; □, whole-locust extract; ●, gibberellic acid, 1 μg per animal. 366 fourth instar *Locusta migratoria* were used and injected 18–30 h after the previous moult

Growth of the internodes of dwarf pea plants is greatly increased by the addition of gibberellic acid. Fractions of the locust extracts have been tested on dwarf pea seedlings, var. 'Meteor', in a standard bioassay for gibberellin activity[2]. Those fractions containing large amounts of ecdysone-λ exert a significant stimulation of growth (Fig. 2), corresponding to approximately 10 per cent of that exerted by gibberellin-A_3.

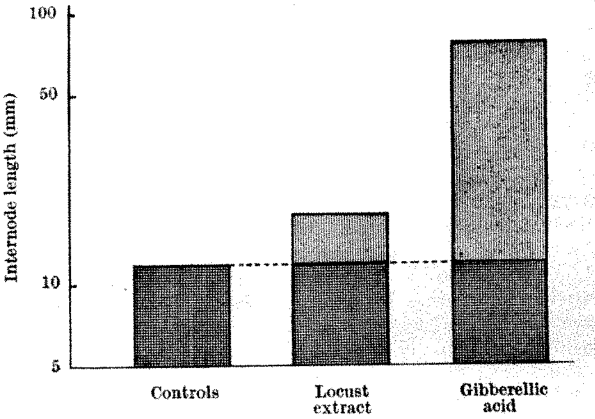

Fig. 2. The mean internode length in dwarf peas var. 'Meteor' treated with solvent alone ('controls'), with the same locust extract as that used in the the experiment illustrated in Fig. 1, and with gibberellin-A_3. The dose of the latter material was chosen to produce optimal growth. 108 plants were used; 3 internodes per plant

Thus the insect growth-substance ecdysone-λ and the plant growth-substance gibberellic acid have similar effects on both plants and locusts.

MICROBIOLOGY

Differences in the Mode of Action of Strepzyme and *Helix pomatia* Enzyme Preparations on *Trichotecium roseum* Spores

For the past months, we have been examining the lytic agents affecting yeast and mould cell-walls. Micro-organisms capable of lysing the cell-walls of these organisms were isolated from soil samples. The digestion of the cell-wall material of mould spores, by means of a partially purified enzyme produced by the *Streptomyces GM*, has been described already in a previous communication[1]. Some of us, using the method of digestion by the strepzyme or the gastric juice of the snail *Helix pomatia*, have published several reports on their investigations with protoplasts prepared from various moulds[2-5]. The results obtained clearly demonstrated that protoplasts of *Trichotecium roseum* could be produced by using the lytic enzymes under appropriate experimental conditions.

This communication describes the production of protoplasts from *T. roseum* spores and the differences in the mode of action of the lytic systems used during this investigation. As test organism a young sporulated culture of *T. roseum* was used, growing it at 28° C for 4 days in a medium of the following composition: glucose 10 g; asparagine 1 g; yeast extract 0·5 g; K_2HPO_4 0·5 g; $MgSO_4.7H_2O$ 0·5 g; $Fe_2(SO_4)_3$ 0·01 g; tap water 100 ml. and distilled water 900 ml.

Spores were recovered from the media by careful shaking with sterile distilled water and sedimentation in a low-speed centrifuge. 0·5 ml. of washed suspensions of spores, adjusted at about 10,000 spores per ml., was incubated with 0·5 ml. of the concentrated lytic enzyme solutions (strepzyme or a gut juice preparation from *Helix pomatia* obtained from L'Industrie Biologique Française) in the presence of 0·1 M phosphate buffer *p*H 6·8 or 0·1 M phosphate–citrate buffer *p*H 5·8, both containing 0·8 M mannitol as a stabilizing agent. The digestion of the cell wall was allowed to take place with gentle shaking at 25° C for 16 h for the liberation of the protoplasts.

Examination under phase-contrast microscope shows that when the gut juice preparation from *Helix pomatia* is used the first visible effect of the enzyme is that the spores become partially detached from the cell wall. The rupture of the cell wall starts at the polar end of the cell that was in contact with the conidiophore and then the other one. The protoplasts can be seen to emerge through the aperture attaining a spherical shape (Fig. 1). The protoplast nature of these structures can be demonstrated simply by dilution of the medium with water when the protoplasts will burst.

On the other hand, when a *T. roseum* spore undergoes the digestive treatment using the strepzyme it was seen that, as previously described, the lytic attack on the cell-wall and the cross-wall is very uniform, giving rise to the formation of two protoplasts which rise together and at the same time from the previous double-dotted cell spore.

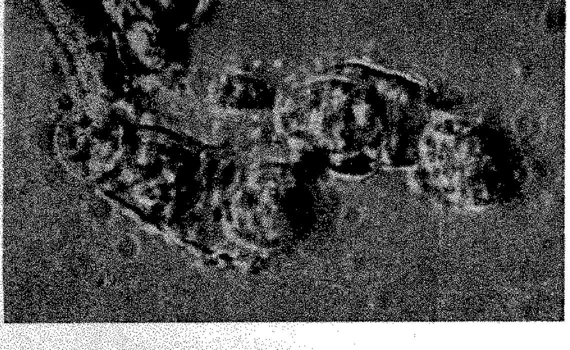

Fig. 1. Shows protoplast formation, after the digestion with the enzyme preparation from *Helix pomatia*. The protoplasts leave the cell-wall at both ends of the double-dotted cell spore of *T. roseum*

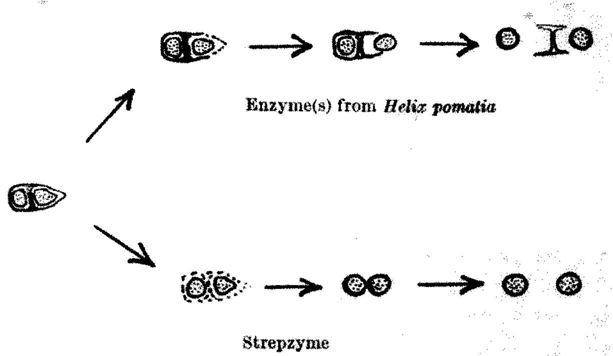

Fig. 2

Fig. 2 shows, diagrammatically, the two different stages in the release of protoplasts from the double-dotted cell spores of *T. roseum*.

These preliminary experiments have shown that the strepzyme produces protoplasts from *T. roseum* spores completely deprived of residual cell-walls which represents a great advantage on the enzyme preparation from *Helix pomatia*.

This investigation was supported by a grant from the Ministry of National Education, Spain.

A Rapid Method for Determining Phytase Activity of Soil Micro-organisms

During an examination of the breakdown of organophosphorus compounds by soil micro-organisms it was found necessary to determine phytase activity in a large number of isolates. The following modification of a recently published technique[1] for the detection of glutamic acid decarboxylase in bacteria proved suitable for this purpose.

Organisms to be examined were grown as streak cultures on glucose–nutrient agar plates incubated at 23°. When sufficient growth had been obtained it was treated with toluene vapour, as described by Stewart[1], and transferred by means of a platinum loop to small tared filter paper disks (7/16 in. diam. Whatman No. 1 filter paper) in 30-mg (wet weight) amounts. A torsion balance was used for rapid weighing in this operation. Organisms (for example, Actinomycetes), the growth of which is difficult to remove from agar, were grown on 'Cellophane' laid on the solidified agar surface. This facilitated removal of the growth and prevented its contamination with agar. After weighing, the disks plus organism were inverted on to glass coverslips and gentle pressure was applied to ensure the formation of a uniform layer of organism between disk and coverslip. Sodium phytate solution (0·01 ml. containing 20 μg phosphorus) was added from an 'AGLA' micrometer syringe (Burroughs Wellcome, Ltd.) to the disks, which were then incubated at 23° for 3 h in a moist atmosphere. Control disks were prepared in exactly the same way except that the sodium phytate was added at the end of the incubation period. In general the *p*H of both sets of disks fell within the range of

4·5–5·5. To stop further activity after incubation, one drop of 10 per cent trichloroacetic acid was added to both sets of disks, which were then extracted in a little water, centrifuged and the supernatants analysed for inorganic phosphate by a modification[2] of the method of Dickman and Bray, using an EEL colorimeter with red filter *OR*1. Table 1 gives the results obtained for a number of organisms.

Table 1. PHYTASE ACTIVITY OF MICRO-ORGANISMS

Organism	Inorganic phosphorus in control disk (μg)	Inorganic phosphorus in experimental disk (μg)	Percentage hydrolysis of sodium phytate
Aerobacter aerogenes	5·0	15·0	50
Rhodotorula sp.	1·25	4·75	17·5
Streptomyces sp.	7·00	10·5	17·5
Bacillus sp.	15·0	25·0	50
Unidentified short Gram-negative rod	8·0	28·0	100
Unidentified Gram-negative pleomorphic rod	9·75	17·25	37·5

The reproducibility of the method was checked using a strain of *Aerobacter aerogenes* and the following results, expressed as μg phosphorus released, were obtained for five replicates disks: 10·0, 9·5, 9·80, 10·0, 10·5.

This method has shown that 30–50 per cent of the organisms in soil and on plant roots possess an enzyme capable of hydrolysing sodium phytate with consequent release of inorganic phosphate. Further details of this work will be published elsewhere.

We thank Dr. F. W. Norris of the University of Birmingham for supplying the pure recrystallized sodium phytate used in this work.

Facilitation of the Removal of the Total Surface Growth of Bacteria from Solid Media

To make a suspension of bacterial colonies by removing them from the surface of culture media, using a wire loop, is often difficult. In using a wire loop for this purpose the growth generally slides over the wire of the loop, and the complete removal of all surface growth is thus rendered both difficult and time-consuming.

It has been found that if a wire loop is first charged with a film of liquid before attempting the removal of surface growth and then run across the bacterial colonies growing on the plate, the film of liquid allows the colonies to collect in the loop.

In practice the technique used is to sterilize the loop (2·5 mm diam.), cool in the suspending liquid, remove the loop being careful not to break the liquid film, touch off the excess liquid, run the side of the loop across the plate with the loop at right angles to the surface of the agar, continue running the loop across the bacteria until completely full, shake off into the suspending liquid and start the cycle again.

By using this technique the whole growth from a standard Petri dish can be removed in ten such operations. The use of this procedure reduces the risk of contamination associated with the more usual techniques utilized for this purpose.

ENTOMOLOGY

Oviposition on Dry Surfaces by *Anopheles* (*Cellia*) *gambiae* Giles

UNTIL now, it has been held that, before any species of mosquito will oviposit, water must be present as surface moisture or as a collection[1]. Some forty-two years ago, however, Wesenberg-Lund[2] recorded *Aedes* (*Ochlerotatus*) *communis* (De Geer) ovipositing among superficially dry leaves on a dried lake bed and under leaves in the laboratory, and concluded that this mosquito probably lays its eggs on dry earth. The observations recorded here have shown definitely that *Anopheles* (*Cellia*) *gambiae* Giles will oviposit on absolutely dry surfaces (at least in the laboratory), if the gravid female ready to lay its eggs is denied access to water. The eggs so oviposited, however, fail to turn black and are not viable. A survey of the literature locally available has revealed no definite previous record of oviposition on dry surfaces by mosquitoes.

Fully gravid *A. gambiae* females were put in 8 in. × 8 in. × 8 in. and 11 in. × 11 in. × 10 in. cages, in lots of 50 and 100–200 per cage, respectively. Each cage had a sheet of dry white blotting paper covering the entire floor area. No water was provided for oviposition. The mosquitoes were maintained at 25° C and 85 per cent relative humidity, and were subjected to 12 h light and 12 h dark in each 24 h.

After a day or two, several of the females in a cage were observed to have flat abdomens (that is, in Sella's stage I[3]). At first, this was puzzling, since, at a casual glance, the familiar black eggs of mosquitoes could not be seen on the blotting paper. It was only later that thorough examination with a magnifying glass revealed numerous off-white eggs on the blotting paper, indicating that oviposition was taking place in the absence of water.

It was assumed that since mosquito eggs on a dry surface are subjected to maximum exposure to oxygen, this should facilitate tanning and melanin formation. Yet eggs oviposited on dry surfaces failed to darken. It was then thought that perhaps a gravid mosquito denied access to water, when it is ready to oviposit, might undergo some physiological change affecting the eggs; so that when and wherever these are laid, darkening would be inhibited anyway. This hypothesis was tested using the arrangement shown in Fig. 1. Those eggs which were trapped into the funnel and succeeded in reaching the water below, through a very tiny hole at the apex of the filter-paper cone, became black and were viable; those which fell on to the dry blotting paper on the floor or remained on the dry surface of the filter-paper cone retained their pale coloration and were not viable. This indicates that eggs oviposited on dry surfaces are basically normal. With regard to coloration, it might well be that eggs laid on a dry surface would lose water from the chorion so rapidly that this would inhibit darkening (Prof. V. B. Wigglesworth, personal communication), and it is known that if the eggs of anopheline mosquitoes are removed from contact with water immediately after being laid, they retain their pale coloration[4].

Whether oviposition on dry surfaces occurs under natural conditions is at present unknown; but the presence, during the dry season, of *A. gambiae* females with well-developed eggs and ready to oviposit as soon as a certain degree of mean relative humidity is reached has been reported by a number of workers[5]. A comprehensive study of the age composition and oviposition habits of dry-season populations of this mosquito might prove to be of more than academic interest; for if it can be shown that oviposition on dry surfaces does occur in the field (with the result that further blood-taking is not held up), this would contribute immensely to our understanding

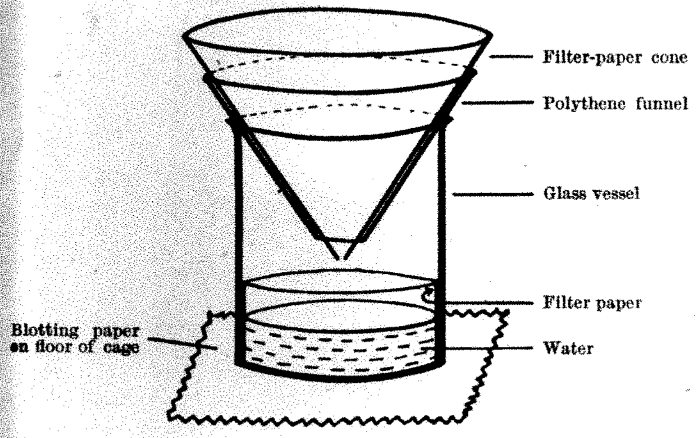

Fig. 1. Method of trapping into water eggs laid on a dry surface

of the continuity of endemic malaria in the savanna regions of Africa.

I thank Prof. V. B. Wigglesworth for his advice.

Parthenogenesis in the Cattle Tick, *Boophilus microplus*

Although bisexual reproduction is usual among ticks, there have been reports of parthenogenesis in various species including *Amblyomma agamum*[1], *Rhipicephalus bursa*[2], *A. dissimile*[3], *Hyalomma anatolicum*[4], *Ornithodorus moubata*[5], and *Haemaphysalis bispinosa*[6]; but there appears to be no previous record of parthenogenesis in *Boophilus microplus*. In fact, it was considered by many workers on the cattle tick in Australia that *B. microplus* females were unable to complete engorgement in the absence of males, and it was reported[7] that female cattle ticks isolated from males in small areas on a sheep by means of repellent barriers did not engorge completely. Furthermore, Riek[8] observed that unfertilized female cattle ticks remained attached to mice for considerable periods without engorging. In both instances the subsequent introduction of males led to rapid engorgement of the females.

It has now been shown that in the Yeerongpilly (Queensland) strain of *B. microplus*, 62 per cent of 185 females, freshly moulted from individually tubed, replete nymphs, engorged and detached from a steer in the complete absence of males. Fifty-five per cent of these unmated engorged females produced some viable eggs, the hatch of individual egg masses ranging from 0·1 to 48 per cent (mean of 2·2 per cent) when stored at 80° F and 80–90 per cent relative humidity. By comparison, it is usual under these conditions of temperature and humidity for more than 95 per cent of engorged females detaching from artificially infested cattle to lay large numbers of viable eggs, most egg masses having a high percentage hatch (Hitchcock[9] recorded a hatch of 84 per cent at 79° F and 85 per cent relative humidity). In another experiment, unmated females took significantly longer to engorge, and the mean engorged weight was significantly less than for mated females raised on the same steer. Unfertilized eggs had a longer minimum developmental period than fertilized eggs.

Various malformations appeared in parthenogenetic embryos and larvæ, but 2 per cent of parthenogenetic larvæ attached to a steer and reached maturity. All the adults detected, after careful searching of the 1-in.-diam. areas of skin exposed to ticks under the confining box, were female, suggesting a form of thelytoky. Seventy per cent of these fatherless females engorged to medium size or larger, 45 per cent gave eggs and 22 per cent produced progeny. Thus, about 0·25 per cent of first generation parthenogenetic larvæ were capable of reaching maturity and then of giving rise to a second generation without males. Only 2 second-generation fatherless females were obtained (no males), but one of these gave rise to third-generation parthenogenetic larvæ.

It is unlikely that a parthenogenetic laboratory strain of *B. microplus* will be established from this stock. However, the other exotic cattle tick in Australia (*H. bispinosa*) has been shown by Bremner[6] to reproduce by obligate parthenogenesis in one Queensland strain, males being rare and nonfunctional, although in Japan[10] a strictly bisexual race as well as a parthenogenetic race of this latter species is known to exist.

It is not certain whether this phenomenon demonstrated for *B. microplus* can be regarded as true facultative parthenogenesis or whether it is accidental parthenogenesis which, according to Bergerard[11], does not establish itself in Nature. Further work is also required to disclose the type of cytological mechanism involved, to see whether parthenogenesis occurs in other strains of the cattle tick and to determine if it has any significance so far as control and eradication programmes are concerned.

A Non-colonizing Aphid Vector of Potato Virus Diseases

It is now well established that migrating aphids alight in, and feed on, crops which they are unable to colonize[1], and Broadbent[2] has pointed out that such aphids may be responsible for the spread of virus diseases within those crops. An aphid which appears to fill this role in the case of two potato stylet-borne viruses, potato virus *Y* (PVY) and potato virus *A* (PVA), in certain districts of Northern Ireland, is *Brachycaudus helichrysi* (Kltb), the leaf-curling plum aphid.

The possibility that *B. helichrysi* might be responsible for the spread of these two diseases which occasionally occurs in Northern Ireland[3,4] was first considered in June 1961; at that time winged forms of the aphid were found feeding on about 40 per cent of the potato plants (3–6 in. high) in a field located near the site of an earlier outbreak of PVY.

In a small preliminary experiment to test the vector ability of the aphid, winged migrants, taken from infested damson (*Prunus* sp.) foliage, were allowed to feed on the sprouts of PVY infected tubers before being transferred to ten virus-free sprouting tubers. The test plants, together with controls, were grown under insect-free conditions and two of them developed symptoms of PVY; the infections were confirmed by sap inoculation to tobacco and by growing the progeny.

In 1962 a more detailed investigation was undertaken involving both PVY (20 tests on sprouting tubers of the variety Arran Pilot), and PVA (19 tests using the variety Ulster Torch). Winged aphids were collected from infested blackthorn (*P. spinosa.* L.) foliage and 'fasted' (1–24 h) before being fed briefly on virus-infected sprouting tubers. Following the acquisition feed the aphids (1–4 per test) were immediately transferred to the sprouts of healthy tubers, where they were left to feed, generally for two days, before being recovered and preserved as a check on their identity. The test tubers were all 'virus tested nuclear stock' material but, to provide additional evidence of their health, as many as possible were halved before use (PVY, 17 and PVA, 10) and the other half of each was used as a control. With each virus three positive transmissions were effected and of these only two, both PVA, lacked individual control halves. The presence or absence of virus infection in all test and control plants was determined by sap inoculations to tobacco, both from the parent foliage and from the sprouts of the tuber progeny.

The ability of the aphid to transmit these diseases under simulated field conditions was also demonstrated in an experiment using outdoor cages. Ten virus-tested nuclear stock tubers, variety Arran Pilot, were cut lengthwise and the halves of each planted in two separate cages; two tubers infected with PVY were also planted in the centre of each cage. During the period in which the plants were emerging through the soil, twigs of damson infested with *B. helichrysi* were introduced into one of the cages, but no aphids were added to the other cage, which was left to serve as a control. A similar experimental layout, but using tubers of the variety Ulster Torch, was utilized to test the aphid with PVA. Virus transmission was assessed by sap inoculation to tobacco; in the test cages four Arran Pilot plants were found to be infected with PVY and five Ulster Torch plants with PVA: no infections were discovered among the control plants.

The relative vector efficiency of *B. helichrysi* has yet to be determined, but as Kennedy[1] points out "the key considerations affecting the virus-spreading efficiency of a given aphid species are its ability to transmit the virus and the abundance and activity of its winged forms". The ability of this aphid to transmit PVY and PVA has been demonstrated, and in June of this year further evidence was obtained of the large numbers of spring migrants which settle into potato crops when these are situated near the aphid's primary hosts. Two such crops were kept under observation during the early susceptible[5] stage of growth and, at the height of the aphid's migration, vagrant alatæ were found feeding on 70–80 per cent of the plants, then no more than 9 in. high. The highest number of aphids recorded on a single plant was five and the average per infested plant examined was two.

From the evidence presented it is suggested that in years when the spring migration of *B. helichrysi* is heavy, and coincides with the emergence of the potato crop, this aphid can bring about a significant spread of either PVY or PVA should sources of infection be present. (Present experiments[6] have shown that the aphid will transmit yet another important stylet-borne virus of potato—the tobacco veinal necrosis virus, PVY^N.)

CYTOLOGY

Chemical Nature of the System controlling Gene Activities in Insect Cells

Salivary glands of *Chironomus thummi* explanted into hæmolymph or saline revert their pattern of gene activities —visible in the giant chromosomes as puffs—to a more juvenile stage[1,2]. It has turned out that this process—called 'rejuvenation'—is due to an influx of Na$^+$ ions into the nucleus. By stepwise changing the Na$^+$/K$^+$

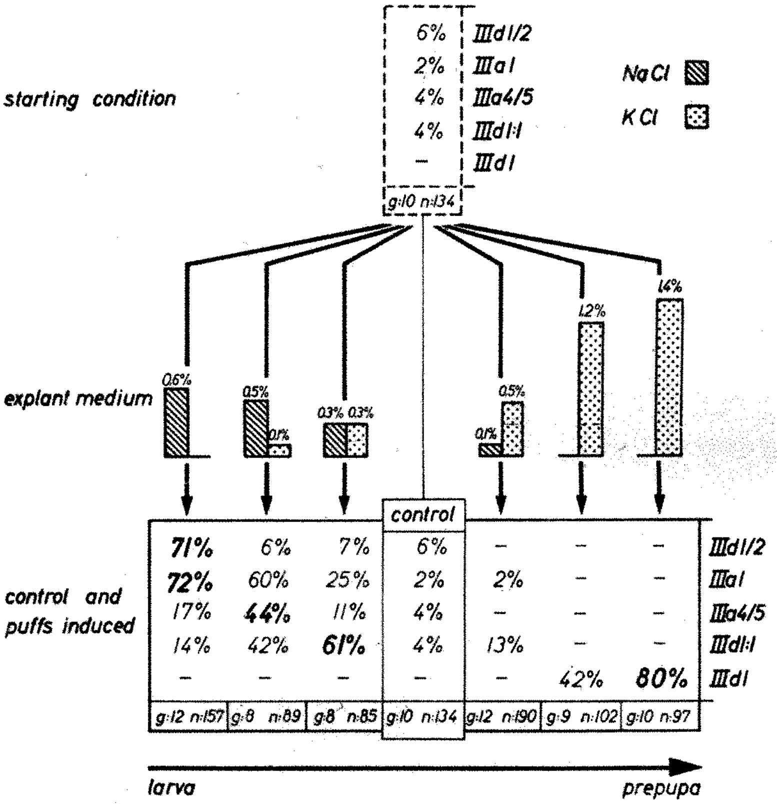

Fig. 1. Induction of puffs in chromosome 3 of *Chironomus thummi* by explantation of salivary glands into media possessing different ratios of sodium chloride and potassium chloride. All media contained 0·021 per cent calcium chloride in addition to the alkali chlorides. 10 control glands (2 arbitrarily chosen sister glands from each group of glands exposed to a different medium) serve to give the puffing pattern of the glands at beginning of experiment. Exposure of glands to explant medium, 2 h; *g*, No. of glands explants; *n*, No. of nuclei with fully analysable 3 chromosome. Figures in body of the Table give percentage of nuclei containing the respective puff. Bold-faced, highest percentage in which a puff is present. Symbols at right: regions (designation after Keyl (ref. 3)) in which the respective puffs appeared. (Illustrations of all puffs in Kroeger (ref. 2) except III *d* 1 : 1, a puff situated between III *d* 1 and III *d* 1/2)

balance in the medium it is possible to activate a graded series of genetic loci, every Na^+ : K^+ ratio inciting different groups of loci to form puffs (Fig. 1). The series of puffing patterns induced by stepwise replacing Na^+ by K^+ is identical with the sequence of puffing patterns which in salivary glands marks the transition from the adult larva to the middle pre-pupa.

In previous experiments[1,2] it was shown that the insect hormone ecdysone, and possibly also juvenile hormone, do not act directly on the genetic loci of a cell but instead exert their effect on a system in the nuclear sap which in turn controls the activity of at least a large fraction of the genetic loci in the chromosomes. It has been concluded that this control system can be present at different levels, each level inciting some loci to become active, others to become inactive. Since the stepwise replacement of Na^+ by K^+ produces the effect of those 'different levels', it seems now that the control system actually consists of the Na^+/K^+ balance in the nuclear sap; both hormones would then act by regulating the ratio between Na^+ and K^+, ecdysone increasing the K^+ concentration, juvenile hormone maintaining a high Na^+ level.

The existence of mechanisms for the extrusion of Na^+ in almost all somatic cells suggests that activation and inactivation of genetic loci by a progressive shift in the Na^+/K^+ balance in the nuclear sap may be a rather universal mechanism.

This work was aided by grants from the Schweizerischer Nationalfonds zur Förderung der wissenschaftlichen Forschung and by the Damon Runyon Memorial Fund (*DRG*-668).

Differential Ribonucleic Acid Synthesis of *X* and Autosomes during Meiosis

SEVERAL investigations[1-3] of chromosomal RNA synthesis during mitosis have established that such synthesis, maximal in interphase, continues during mitotic prophase. It decreases progressively as chromosome contraction advances, none occurring during the fully contracted stages of metaphase and anaphase. RNA synthesis recommences with chromosome despiralization at late telophase.

Only two accounts of RNA synthesis throughout meiosis have been published[4,5]. In one, inorganic phosphorus-32, which is incorporated into DNA, RNA and protein, was used, while in the other, ^{14}C-glycine, ^{14}C-orotic acid and ^{3}H-cytidine were used. The relatively RNA specific precursor, uridine, was not utilized, and the results presented are not entirely unambiguous. RNA synthesis was shown to continue into early meiotic prophase but with some precursors a drop was reported at the time of DNA synthesis and at the zygotene pairing stages.

I have sought more information on this question by following the course of RNA biosynthesis autoradiographically through all stages of male meiosis in the locust *Schistocerca gregaria*, using ^{3}H-uridine. All autosomes actively synthesize RNA throughout the whole of first meiotic prophase. Leptotene and zygotene nuclei are evenly labelled after short exposures to the isotope. After longer exposures the two small nucleoli are noticeably more heavily labelled than the remainder of the nucleus. During pachytene and diplotene the truly lampbrush nature of the fuzzy bivalents is evidenced by their continued synthetic activity. Synthesis decreases progressively during diakinesis, as chromosome coiling becomes more and more complete, and has ceased by the time that nuclear membrane breakdown occurs. No RNA precursor is incorporated into any autosome during first metaphase or anaphase. During second prophase RNA is again synthesized by the uncoiled autosomes. Incorporation decreases as chromosome coiling becomes more advanced and it does not occur at the fully contracted stages of second metaphase and anaphase.

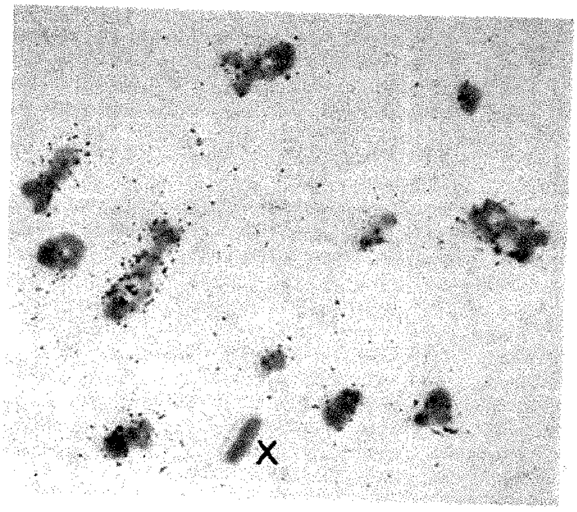

Fig. 1. Diakinesis in *Schistocerca gregaria* showing the distribution of newly synthesized RNA, labelled with ^{3}H-uridine. All autosomal bivalents are labelled, but the *X* univalent is not

Throughout most of meiosis the single *X*-chromosome is allocyclic relative to the autosomes. It is tightly coiled and heavily staining during both first prophase and, in those cells in which it is found, second prophase. In this condition it is synthetically inactive. No RNA precursor is incorporated and the *X*-chromosome is unlabelled throughout its entire length (Fig. 1).

Effect of *p*H and Temperature on Cell Re-aggregation

THE successful re-aggregation of cells has been used widely as a test for their adhesiveness[1,2]. Moscona[1] observed that the re-aggregation of chick embryonic cells does not occur at temperatures at or below 15° C. Steinberg[2] found that re-aggregated cells did not de-adhere at low temperatures and re-interpreted Moscona's results by suggesting that the initial adhesions of cells alone were prevented below such temperatures. Both authors interpreted their results to indicate that the adhesion of cells in re-aggregation involves a temperature-dependent mechanism. Similarly, Steinberg[3] argued that since amphibian embryonic cells could not re-aggregate at *p*H 4·0, carboxyl ionization and calcium-linked binding between cell surfaces are probably involved in cell adhesion. It remains possible that the failure of re-aggregation in these systems was due to the particular conditions of re-aggregation used, and that low temperature or *p*H values do not of themselves generally impede the adhesiveness of normal viable cells. Successful re-aggregation of cells at low temperatures or *p*H values will demonstrate that low temperature and *p*H do not in themselves necessarily affect cell adhesion. The following tests show that this suggestion is probably correct and that other conclusions can be drawn about the modes of cell adhesion.

Cells from 5-day embryonic chicks and gastrula stages of the amphibian, *Xenopus laevis*, were used. In examining the effects of temperature chick limb-bud or liver cells were used, being disaggregated by treatment for 5 min with 0·002 M *p*H 8·0 solution of ethylenediamine tetraacetate made up in Hanks's calcium- and magnesium-free saline, followed by washing and mechanical disruption in Hanks's calcium- and magnesium-free saline. The cells were centrifuged at 50*g* for 1 min to sediment all but single cells, and from the supernatant single cell suspensions about 1·5 million ml. were prepared in the culture media. Single cells accounted for > 98 per cent of cells in all suspensions. Four culture media were used; the first medium (1) was composed of horse serum (Burroughs-Wellcome No. 2), Medium 199 (Glaxo Laboratories) and Hanks's saline in equal proportions. This and all other media were sterilized and freed from dust by filtration ('Millipore', *HA* filters). The other media used in testing the effect of temperature on re-aggregation were as follows: (2) serum-free medium, equal parts of Hanks's saline and Medium 199; (3) medium 2 with 1/3 per cent v/v horse serum; (4) medium 2 with 3 per cent v/v horse serum. After suspension in one or other of the media (diluted with about 15 per cent Hanks's calcium- and magnesium-free saline) the cells were shaken in a constant temperature bath at 92 i.p.m. for 20–36 h. At 36° C re-aggregation, as judged by the appearance of macroscopic coherent re-aggregates and by the reduction of the population of single cells in the medium to about 0·08 million/ml., was extensive in all media. At 6° C or 3° C only one visible re-aggregate was found in 6 flasks using medium 1, though a certain degree of adhesion occurred since the single cell density was reduced to between 60 and 40 per cent of its initial value, numerous cell pairs, triplets, etc., being formed. In the serum-free media extensive visible coherent re-aggregation occurred and the population of single cells was reduced to about 0·08 million/ml. A similar situation was found in medium 3 but more single cells were found (mean 0·2 million/ml.) and rather fewer and smaller visible aggregates formed. With medium 4 a few visible re-aggregates formed; the single cell population remained high (mean 0·6 million/ml.).

The occurrence of re-aggregation at *p*H 4·0 was tested with both chick and amphibian cells. For chick cells prepared as above, medium 1 and the serum-free medium 2 were buffered at *p*H 4·0 with 0·004 M maleate or acetate-hydrochloric acid buffers or at *p*H 6·7 with added maleate or acetate (0·004 M). *p*H values were checked before and after re-aggregation. At *p*H 4·0 very slight precipitation of serum components occurs. Cells were shaken at 36° C for 36 h: no macroscopically visible re-aggregation of cells was observed in serum containing medium buffered at *p*H 4·0, though the proportion of single cells fell to the same level as in suspensions in which visible re-aggregation occurred. Re-aggregation at *p*H 6·7 was visible and extensive in both serum-containing and serum-free media. At *p*H 4·0 in serum-free media re-aggregation was extremely rapid, visible coherent re-aggregates appearing in 1 h and the population of single cells was reduced below detectable levels. Gastrula cells of the amphibian, *Xenopus laevis*, were disaggregated by a chelating agent technique[4]. The cells were re-aggregated in Holtfreter medium buffered at *p*H 7·2 or 4·2 with acetate or maleate buffers (0·004 M). In still unshaken medium at *p*H 7·2 re-aggregation is extensive whereas at *p*H 4·2 it apparently does not occur. However, it is known that cell movement is essential for amphibian re-aggregation and it was found that cell movement is inhibited at *p*H 4·2 (ref. 5). Providing cell movement artificially, by stirring or shaking the cells gently, produces aggregation at *p*H 4·2.

Warburg manometry of chick cells re-aggregated at 3° C in serum-free media showed that on rewarming the aggregates to 37° C they have the same high respiratory rate as cells re-aggregated at 37° C. This indicates that the chick cells are alive after re-aggregation at 3° C. Thus these results show that there is clear evidence that the re-aggregation of live cells is possible at low temperatures, and in consequence it cannot be argued, as Moscona did, that a temperature-dependent mechanism is necessarily involved in cell adhesion, or, as Steinberg maintained, that the first stage of adhesion in re-aggregation is temperature-dependent. Although examination of sectioned material suggests that re-aggregates formed at *p*H 4·2 are composed of viable normal cells this question of viability is of little importance since the arguments concerning cell adhesion expressed by Steinberg[3] were based on similarly treated cells. These results suggest that serum contains some factor or factors interfering with re-aggregation at about *p*H 4·0 and at low temperatures. The failure of Steinberg to obtain amphibian re-aggregation at about *p*H 4·0 can be explained as being due to the inhibition of cell movement, so that potentially adhesive cells were unable to make sufficient contact for large masses of cells to form. The fact that cells can form adhesions at about *p*H 4·0, where carboxyl ionization on their surfaces is suppressed[6], or at low temperatures, can be explained by lyophobic colloid theory of cell adhesion[5].

GENETICS

Natural Selection on an Isoallele

IN *Drosophila pseudoobscura* a genetic factor has previously been described[1], the only observable effect of which is to cause a small change in the banding pattern of the third polytene chromosome. This factor behaves in crosses as a simple recessive gene, and has been named 'salivary' (*sal*). Because of the recondite nature of its effect, *sal* may be considered an isoallele of a gene for normal banding pattern.

The population cage (*W*–11) on which *sal* was discovered contained the gene sequences Arrowhead (*AR*) and Chiricahua (*CH*). In this population only *CH* homokaryotypes exhibited the altered banding pattern. It may therefore be inferred that *sal* was located only on third chromosomes containing the *CH* gene sequence. That *AR* chromosomes do not in themselves inhibit the expression of *sal* will be shown here.

In population *W*–11 the *CH* gene sequence was anomalously fitter than usual[2]. In order to determine whether this situation was related to the presence of *sal*, three additional populations were set up in the manner described elsewhere[2] and maintained at 25° C. One population (*V*–12) contained normal *CH*, one (*V*–13) contained *AR*, and one (*V*–14) contained Standard (*ST*), each together with *sal*-bearing *CH* chromosomes. All the initial flies were F_1's of crosses between the stocks used, ensuring equal initial frequencies of the two genotypes in each case. Generation time under the conditions of this experiment has been estimated[2] at 29 days. Three hundred chromosomes were examined in each egg sample.

The observed frequencies of *CH* chromosomes are presented in Table 1 and Fig. 1, together with results of three comparable previous populations[3,4], each of which contained *AR* and normal *CH*. It has been found by others[5] that populations containing either *ST* and normal *CH* or *AR* and normal *CH* attain equilibrium frequencies of normal *CH* similar to each other. It is apparent from

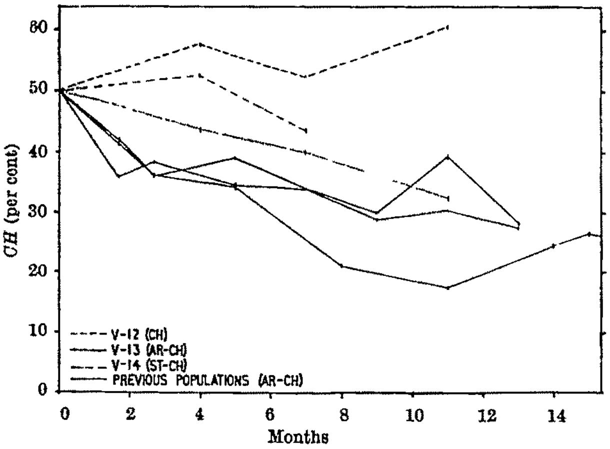

Fig 1 Frequencies of *CH* chromosomes in the populations For population *V*–12 the frequencies are the calculated frequencies of the *sal* gene

our results that *CH* chromosomes containing *sal* (and the alleles in its vicinity) are at least as fit (*V*–13) as, and are in some cases (*V*–12 and *V*–14) clearly fitter than, normal *CH* chromosomes In the absence of an attained equilibrium, no estimate is made of the relative fitnesses Population *V*–14 was terminated as a result of contamination with *D melanogaster*, and the others by accidental exposure to an insecticide

Table 1 Observed Percentages of *CH* Chromosomes in Population Cages

Month	*V*–13 (*AR-CH*)	*V*–14 (*ST-CH*)
0	50 0	50 0
4	43 7	52 7
7	40 0	43 7
11	32 3	—

Because *sal* is recessive, its frequency in a homokaryotypic population could be estimated only from the frequency of homozygotes The frequencies of the various *AR*, *ST*, and *CH* karyotypes in our populations followed the Hardy–Weinberg expectation, and it is assumed that the frequencies of the *sal* genotypes did also The observed frequencies of *sal* homozygotes in *V*–12, *V*–13, and *V*–14 are presented in Table 2, and the calculated frequencies of *sal* in *V*–12 are given in Fig. 1 Population *V*–12, containing only the *CH* gene sequence, confirms that *CH* chromosomes bearing *sal* are fitter than those lacking it

Table 2 Observed Frequencies of Homozygotes for *sal* in Samples from Population Cages The Numerator in Each Case represents Homozygotes for *sal*, the Denominator, all Larvæ of the Designated Karyotype

	V–12	*V*–13			*V*–14		
Month	*CH/CH*	*AR/AR*	*AR/CH*	*CH/CH*	*ST/ST*	*ST/CH*	*CH/CH*
4	$\frac{50}{150}$	$\frac{0}{52}$	$\frac{1}{65}$	$\frac{31}{33}$	$\frac{1}{35}$	$\frac{3}{72}$	$\frac{41}{43}$
7	$\frac{41}{150}$	$\frac{0}{61}$	$\frac{0}{58}$	$\frac{31}{31}$	$\frac{0}{52}$	$\frac{2}{65}$	$\frac{31}{33}$
11	$\frac{55}{150}$	$\frac{0}{68}$	$\frac{0}{67}$	$\frac{15}{15}$	—	—	—

There are a few instances (Table 2) of *CH* homokaryotypes lacking the phenotype of *sal* and of heterokaryotypes (and even of one *ST* homokaryotype) having this phenotype The most likely explanation of these unusual combinations appears to be crossing-over Incomplete penetrance of *sal* is ruled out by the presence (in equal frequency) of both kinds of expected recombinants and by tests of the homozygous *sal* stock A frequency of crossing over of 0 002 (0 2 recombination units) between the *CH* inversion complex and *sal* would (in the absence of greatly changed selection on recombinants) account for the observed frequencies of separation between them, within the limits of sampling error Results of crossing over in inversion heterozygotes of the third chromosome of *D pseudoobscura* have been published by others[6,7] The position of none of the mutants used in those experiments is known with sufficient precision[8] to be able to determine whether or not the frequency of 0 002 is a value of recombination expected between the distal end of the *CH* inversion complex and any more distal mutant, in a heterozygote with *AR* or *ST*. However, such a frequency is at least easily consistent with the available data

As usual in competition experiments with single genes, it is unknown whether the observed difference in fitness between *CH* chromosomes containing *sal* and those lacking it is due to a direct effect of *sal* itself (and if so whether it is a result of the effect on chromosomal banding) or to closely linked genes

These experiments were conducted in the laboratory of Prof Th Dobzhansky at Columbia University. During this time, one of us (L V) was the recipient of a Boese postdoctoral fellowship from Columbia University

Selection in Natural Populations: Human Fingerprints

In order to estimate the normal intensities of natural selection on quantitative characters, characters must be chosen for reasons other than the likelihood of natural selection operating on them[1] This communication deals with one suitable character

The data consist of total ridge-counts[2,3] of about 250 English families Counts for at least one parent and one child were available for each family used; usually the entire family was available The sample is not a random sample of any particular community, but is more or less representative of England as a whole The restriction to families ensures that the same bias is present in each generation, the possible effects of migration are thereby also excluded.

The use of comparisons between a set of parents and the set of their offspring as a means of investigating natural selection is to my knowledge new and requires comment It is not equivalent to determining the change, if any, between successive generations, because the generations were sampled at different ages Its main advantages are the relative ease of collecting results for man and the elimination of a possible bias due to differential migration; it has, however, relatively poor power For a less highly heritable character than ridge-counts, and especially for the variance of such a character, a difference between age-groups of the same generation, sampled at different times, may be present with only a much smaller difference between generations, even if reverse selection on fertility is absent For the variance this may or may not be true in the present case A change in environmental effects between generations would be confounded with a result of selection, but the presence of a total phenotypic change (including any change in environmental effects) can be tested for by comparing unrelated individuals a generation apart Strong differential mortality in this interval would, however, also produce a difference in the distributions of phenotypes.

Ignoring environmental effects and considering less highly heritable characters than fingerprints, the children are essentially a random sample of the population from which their parents were drawn. The two selective barriers which must be passed in this direction are survival for the length of one generation and the production of one or more viable children. Differential fertility, prezygotic selection, and prenatal and juvenile mortality are the selective barriers actually passed from the sample of parents to that of children. For a character as highly heritable as ridge-counts[4,5] only the second direction of comparison is valid. The statistics are the same for both directions.

The individuals were divided into four classes: fathers, sons, mothers, and daughters. No individual was included in more than one class, and the occasional twins were counted as two individuals. Means and variances of total ridge-count were computed for each class, and are given in Table 1. It is evident that no significant difference is present between the generations for either sex. The statistic Q, useful in comparing estimates of selection for several characters, is the ratio of the observed difference between means to the difference expected 50 per cent of the time by chance for the same sample size[1].

Table 1. STATISTICS FOR TOTAL RIDGE-COUNT (THE STATISTIC Q IS EXPLAINED IN THE TEXT)

	N	s^2	$\bar{X}$	F	Q	$C.V.$
Fathers	231	2,899	139·7 ± 3·5	1·10	1·83	38·5
Sons	283	2,645	145·5 ± 3·1			35·4
Mothers	249	2,749	127·3 ± 3·3	0·92	0·168	41·2
Daughters	276	3,001	126·7 ± 3·3			43·2

The high coefficients of variation are notable, particularly for a non-vestigial character. This is probably not due entirely to the character being composed of separately inherited divisions, because the three conventional classes of fingerprints (arch, loop, and whorl) more or less grade into each other and the total distribution of ridge-counts is bell-shaped[6]. It could be a result of the absence of any selection affecting this highly heritable trait, or it could be a result of heterosis, epistasis, or destabilizing selection, too weak to be detected by the present sample size.

This work was supported by a NATO post-doctoral fellowship. The data were collected by Dr. S. B. Holt for other purposes, and I thank her for permission to use them.

Allelism of Silver, Gold, and Imperfect Albinism in the Fowl

WERRET *et al.*[1] described a series of matings, starting with a non-silver male resulting from a cross of a Brown Leghorn sire by a Light Sussex dam, which suggested that the gene for silver (S) had mutated to that for semi-albinism, designated by them as s^{al}. As the mutant gene also proved to be recessive to that for gold (s), together they formed a series of three alleles at one locus on the sex chromosome. Mueller and Hutt[2] first described imperfect or semi-albinism (al), and afterwards Hutt[3] reported on the linkage relationships of his al to other genes on that chromosome. Although Hutt had no specific tests of linkage of al with S, both these genes were tested with others located nearby. Identical linkages (0·7 per cent) were found with the gene for dwarf (dw), but for the gene for rapid feathering (k), where there were more gametes tested and the map distance was considerably less, k was closer (1·6 per cent) to al than to S (2·8 per cent), a situation that did not suggest possible allelism. Hutt therefore placed al between S and k, a little closer (1·2 per cent) to the former.

Because of the apparent closeness of the two loci, the observations of Werret *et al.* could also have been explained by assuming a small deletion rather than a point mutation. It was also possible that they were dealing with a different mutation from that studied by Hutt, which is known to have occurred several times[4]. Either possibility could account for the poor growth rate and defective vision described by Werret *et al.* Neither condition was characteristic of the albinos studied by Hutt, nor is it of those at present on hand here.

(*a*) *A test to determine presence of S or s in albinotic females.* If the gene for albinism (s^{al}) be a third allele at the S–s locus, the hemizygous albinotic female can possess neither S nor s. A small group of albinotic females, derived from a different source[5], were therefore crossed to a Rhode Island Red sire. Some of the dams were heterozygous for I or E, or both genes. However, among the resultant chicks which could be classified for basic down colour (those with columbian plumage pattern, ee), none was silver male. This proved only that the albinotic dams did not carry S, but it did not prove that they did or did not carry s. These same albinotic dams were then mated to a Light Brahma male (ee) in which both sex chromosomes carried S and presumably Al. The male offspring that were silver (S ?) and showed columbian pattern (ee) were then backcrossed to Rhode Island Red females (s- and ee). The resulting progeny were all classifiable as silver or gold, or as albinos (females only).

Among 2,492 progeny from the six F_1 sires tested, the ratio of silver (S) to non-silver (s or albino) was 1,248 to 1,244. Among the 1,272 female chicks there were 657 non-albino silvers to 615 albinos, most of the latter showed a reddish tinge in their down. There were no gold females! If the original albinotic dams had carried gold (s) in addition to al, the F_1 sires would have been heterozygous for both genes ($S\ Al/s\ al$) and there could have been a crossover to yield a gold non-albinotic pullet ($s\ Al$ / – –). With the suggested map distance of 1·2 units between the two genes[3] there should have been at least 15 cross-overs. Half would have been silver albinos which might not be distinguishable from gold albinos. The others would have been gold females and there would be no doubt about classification. The fact that none of these was found indicates that the gene for albinism is an allele of S and s.

(*b*) *Evidence of normal crossing-over in the sex chromosome of sires heterozygous for albinism.* As the albinotic dams were rapid feathering (k –) while the Light Brahma sire was slow feathering (KK), the F_1 males were therefore dihybrids, Kk, Ss^{al}. The Rhode Island Red dams used to produce the back-cross progeny were gold and rapid feathering ($s\ k$ / – –). Thus the presence in the F_1 males of the genes for rate of feathering in the coupling phase with those for down colour made it possible to determine from their progeny the amount of crossing-over between the S and K loci. Classifications of all chicks were as follows:

Parental types			Cross-over types		
SK ♂♂	—	574	*Sk* ♂♂	—	17
sk ♂♂	—	610	*sK* ♂♂	—	19
SK ♀♀	—	651	*Sk* ♀♀	—	6
alk ♀♀	—	601	*alK* ♀♀	—	14
		2,436			56

Assuming that we are dealing with only two loci, the rate of crossing-over was 2·25 per cent, which agrees very well with Hutt's[3] 2·8 per cent and Jaap's[6] 1·3 per cent. The 14 slow-feathering albinotic pullets are proof that crossing-over occurred between genes at these two loci. It seems quite unlikely that if *al* lies between *S* and *k* all the cross-overs would have occurred between *al* and *k* and none between *s* and *al*. If *al* occupies a locus separate from that of *s*, but closer to it than Hutt's data would suggest, then the existence of two separate loci might not be established even with the analysis of more than 600 suitable gametes.

The original albinotic females obtained by Mueller and Hutt and by Cole both showed ghost barring and were probably sired by Barred Plymouth Rock males. In each case the sex chromosome, coming from a Barred Plymouth Rock, would have included the gene *S* closely linked to *al*, if it were not in fact an allele of *al*. However, in the case of the more recent mutation, all albinos tested (8) proved not to carry *S*. While these were 2 or 3 generations removed from the original albinotic dam, it seems highly improbable that *all* would have been derived by crossing-over and show now a very close linkage of *s* to *al*.

On the basis of our present evidence we must conclude that Werret *et al.* were correct in their interpretation that *S*, *s*, and s^{al} form a series of three alleles on the sex chromosome of the fowl.

PSYCHOLOGY

An Ante-natal Determinant of Intelligence

Reliable investigations of intelligence suggest that at least 75 per cent of individual variations in ability are determined by inheritance[1]. The distribution of intelligence appears to be best described by a Pearson type IV curve[2] determined mainly by polygenic factors.

It would appear now that much of the remaining variance of intelligence can be attributed to factors operating during the embryonic development of the individual. One such factor appears to be that of season of birth as a reflexion of climatic conditions during pregnancy.

There have been in the past a number of investigations reporting small but consistent associations between psychological performance and seasonal changes, including season of birth[3]. Such investigations often involve more average ranges of ability than those to be described here. It seems unlikely, therefore, that the latter results are only applicable to the basically low level of this sample.

I have examined[4] a group of 188 adult subnormal patients with intelligence quotients ranging from 40 to 69 (the third and fourth standard deviation ranges below the mean). It was found that birth in summer and autumn was significantly advantageous to subsequent intelligence performance compared with birth in winter and spring.

Further examination revealed that this association between season of birth and subsequent intellectual performance was probably a reflexion of the trend of climatic temperature during the whole of pregnancy. Thus, relatively high intelligence quotients were significantly associated with the number of embryonic months possessing a mean monthly temperature above that month's mean temperature over the years. Table 1 summarizes the intelligence quotient and climatic temperature data for this sample.

Table 1. Seasonal Temperature and Intelligence Quotient

	Summer	Autumn	Winter	Spring
No. of subjects	46	45	47	50
Mean intelligence quotient	57.1	54.6	51.7	53.1
Mean °F	56.5	55.5	40.9	42.3
Mean diurnal variation °F	14.9	12.6	8.3	10.8

The following example highlights the results obtained. Out of the total sample of 188, 10 subjects had an embryonic development with 8 or 9 months all above the respective mean monthly temperature. Of these 10 subjects, 8 fell in the 55–69 intelligence quotient range (third standard deviation below the mean) and only 2 in the 40–54 intelligence quotient range (fourth standard deviation below the mean).

From Table 1 it can be seen that between summer and winter births there is an average difference in intelligence quotients of more than 5 points. It is possible that if appropriate weighting be given to (1) variations in climate from year to year, (2) individual differences in exposure and susceptibility, then the effect of climate during pregnancy on subsequent intelligence might be more than 5 points of the intelligence quotient.

With chromosomal abnormalities, a somewhat similar result has been recently reported[5]. This investigation revealed a significant relationship between climatic temperature at the approximate time of conception and the incidence of mongol births to younger mothers.

From a survey of a number of investigations[6], a relationship has been claimed between season of birth and the incidence of psychosis (especially schizophrenia). However, in a relevant examination[7], I have produced evidence to suggest this might be an artefact of the noted association between intelligence and the season of birth. Nevertheless, one author[8] has found indications that factors during pregnancy, apart from climatic change, might be a determinant of future deviant behaviour.

It is not known how climatic temperature precisely affects the embryo. Further work is required on the precise nature of the temperature effect. This is presumably a matter of relative changes rather than absolute levels, but investigations in parts of the world with differing modes of temperature variation to the British Isles would be of great interest. For example, it can be seen from Table 1 that the amount of diurnal temperature variation is positively associated with the mean temperature-level. It is conceivable that the association between climatic temperature and intelligence is a result of diurnal changes rather than seasonal ones. There are, in fact, parts of the globe where the diurnal range is greater in winter. Such variations of climate clearly offer ready-made experimental designs for investigations into human performance and their determinants. The work recorded here offers one application of such a conceptual framework.

Number of Items presented and recalled as Determinants of Short-term Recall

The percentage of items correctly recalled from a sequence of items decreases as the number of items in the sequence increases[1,2]. Two factors normally vary directly with increasing sequence length: number of items presented and number of items to be recalled. When a twelve-item sequence was presented, Anderson[3] found that increasing the number of items to be recalled from four to eight to twelve increased the rate of error. Further investigation is necessary to determine if this is true substantially above the memory span. The importance of the number of items presented, independent of the number of items to be recalled, has never been adequately investigated. The following experiments on short-term recall of sequences beyond the memory span were designed to determine the independent effects of both these factors.

Using a Wollensak (model *T*-1515-4) tape recorder, 24 subjects were given sequences of digits presented approximately at 1/sec. Subjects had a 25-sec interval between the end of one sequence and the beginning of the next sequence in which to record the digits in order in the appropriate boxes. They were encouraged to guess, but they were not allowed to write down more items than the sequence contained. Subjects were run in two conditions. In condition *P*16-*R*12, 16 digits were presented, but only 12 were to be recalled. The first, fifth, ninth, and thirteenth items were already typed in the appropriate boxes. There were no repeats among the items that were typed-in. In condition *P*12-*R*12, 12 items were presented, and all 12 were to be recalled. Each sequence in condition *P*12-*R*12 was obtained by using the 12 digits to be recalled in a corresponding sequence in condition *P*16-*R*12. A one-second pause in presentation was used in place of each of the four deleted items. Thus, both conditions had the same number of items to be recalled and the same total time of presentation for the 12 items to be recalled. Sequences were randomly selected subject to the constraints that there were no runs of any digit, no forward or backward numerical sequences longer than two, and in *P*16-*R*12 the first, fifth, ninth, and thirteenth items were different from each other. All subjects received 24 sequences in one condition followed by 24 sequences in the other condition, counter-balanced for order. Two alternative sets of both length-16 and length-12 were used so that no subject recalled the same sequences of 12 digits in both conditions.

The data were analysed for ordered recall, item recall and position recall for items. A subject's report of an item is correct by an ordered recall criterion if, and only if, the correct item is recalled in the correct position. A subject's report of an item is correct by an item recall criterion if, and only if, it appears anywhere in his report of the sequence in question. When a digit is repeated in a sequence, a subject must report all occurrences of the item to obtain the maximum item recall score. Position recall, independent of item recall, is obtained by subtracting the item recall errors from the ordered recall errors, reducing the total number of possible errors by the same amount when computing the error rate for position recall.

Table 1 Error Rates for *P*12–*R*12 and *P*16–*R*12 (per cent)

Condition	Trials	Ordered recall	Item recall	Position recall
*P*12–*R*12	1–12	26·71	12·70	16·04
	13–24	19·07	10·10	9·98
	Total	22·88	11·40	12·97
*P*16–*R*12	1–12	43·63	22·77	27·01
	13–24	41·63	20·63	26·47
	Total	42·63	21·70	26·73

Table 1 reports the error rates for ordered recall, item recall. and position recall for the first 12, second 12, and total 24 sequences in each condition. The number of errors in condition *P*16-*R*12 was approximately twice as large as the number of errors in condition *P*12-*R*12 for ordered recall, item recall, and position recall. All differences between the two conditions were significant at well beyond the 0·001 level using a χ^2 test. Comparing the first 12 sequences with the second 12 sequences in each condition, there were significant practice effects in ordered recall, item recall, and position recall for condition *P*12-*R*12 ($P < 0·001$, χ^2 test), but in condition *P*16-*R*12 only the practice effect in item recall was significant ($P < 0·05$, χ^2 test). Items in condition *P*16-*R*12 were analysed into two categories: items identical to any of the items typed-in and items different from the items typed-in in any given sequence. The error rates for ordered recall, item recall, and position recall were computed separately for each of the two item categories in both *P*16-*R*12 and *P*12-*R*12. As expected, in *P*12-*R*12 there were comparable practice effects in both categories of items. However, in *P*16-*R*12, the only significant practice effect was in item recall of items identical to any of the typed-in items. When the number of items to be recalled is held constant, beyond the memory span, it appears that increasing the number of items presented increases the number of errors substantially and diminishes improvement with practice.

Anderson[3] established significant differences in short-term memory when four, eight, or twelve items were to be recalled out of twelve items presented. The following experiment was performed to determine if there is a difference in error rate between recall of 12 and 16 items when 16 items are presented. 24 additional subjects were run in condition *P*16-*R*16 in which 16 items were presented and all 16 were to be recalled. Half the subjects in condition *P*16-*R*16 were given 24 practice sequences before being given condition *P*16-*R*16 in order to make *P*16-*R*12 equivalent in amount of practice to *P*16-*R*12 in the previous experiment. Subjects were instructed to divide the sequence into four groups since division into four groups was achieved by the pauses in *P*12-*R*12 and the typed-in items in *P*16-*R*12. This experiment was identical to the previous experiment in all other respects.

In *P*16-*R*16 the ordered recall rate of error for all 16 items was 44·20 per cent, the ordered recall rate of error for the 12 items identical to the 12 recalled in *P*16-*R*12 was 45·13 per cent. Neither of these rates of error was significantly different from the rate of error in *P*16-*R*16. In *P*16-*R*16 the item recall rate of error for all 16 items was 26·04 per cent; for the comparable 12 items it was 22·61 per cent. The former figure was significantly greater than the item recall error in *P*16-*R*12 ($P < 0·05$, χ^2 test); the latter figure was not. In *P*16-*R*16 the position recall error rate for all 16 items was 24·55 per cent; for the comparable 12 items it was 29·10 per cent. Neither figure was significantly different from the position recall error rate in *P*16-*R*12. No significant improvement occurred with practice in *P*16-*R*16. Increasing the number of items to be recalled from 12 to 16 increased the rate of error, but not very much.

Serial position curves for ordered recall, item recall, and position recall were obtained by dividing the number of errors of each type at each position by the total number of errors of each type. In all three conditions, primacy and recency effects were obtained, with the point of maximum difficulty being the position immediately prior to the middle of the sequence. Superimposed on this overall serial position effect were four smaller serial position effects corresponding to the four groups into which subjects divided the long sequences in each condition. This grouping was the result of the pauses in presentation in *P*12-*R*12, the typed-in items in *P*16-*R*12, and instructions in *P*16-*R*16.

The first item to be recalled (second item presented) in *P*16-*R*12 had an error rate more comparable with the second item to be recalled (second item presented) than to the first item to be recalled (first item presented) in both *P*12-*R*12 and *P*16-*R*16. It appears that the overall primacy effect in *P*16-*R*12 was influenced more by presentation position than by recall position and was therefore greatly reduced. The primacy and recency effects within each group were consistently greater in *P*12-*R*12 than in *P*16-*R*12, presumably resulting from the additional item presented before and after each group in *P*16-*R*12.

Increasing the number of items presented from 12 to 16 doubles the error rate, increasing the number of items to be recalled from 12 to 16 has a much smaller effect. Practice effects the overall serial position curve and within-group serial position curves are affected more by the number of items presented than by the number of items to be recalled, when the number of items presented and recalled is well beyond the memory span as it is in the experiments reported here These findings suggest the general conclusion that the number of items presented is a more important determinant of short-term memory above the memory span than the number of items to be recalled

The decrement in short-term recall produced by increasing the number of items presented and the relatively small improvement with practice suggests that human beings are not able to ignore an item that need not be remembered when it is embedded in a sequence of items that are to be remembered Perhaps the item before the item that need not be remembered is automatically associated to the item that need not be remembered, and this unnecessary association competes with the necessary association between the two items surrounding the item that need not be remembered Alternatively, subjects may not even attempt to learn 12 item sequences in *P*16-*R*12 and may rehearse and recall these sequences the same as ordinary 16 item sequences In either case it appears that the human short-term memory system is unable to ignore the extra items

The relatively small effect of increasing the number of items to be recalled from 12 to 16 contrasts sharply with Anderson's findings for increases from four to eight to twelve[3] It appears that the number of items to be recalled is a much more important variable below or in the vicinity of the memory span than it is above the memory span Subjective reports suggest that there are two stages in short-term recall first, a rapid ordered recall output of those items of which one is surest and, then, a slower free recall output of those items which one thinks were probably in the sequence The ordered recall mechanism is assumed to be more accurate than the free recall mechanism If there are these two semi-independent mechanisms for short-term recall, then the findings concerning the importance of the number of items to be recalled suggest that the ordered recall mechanism is much more vulnerable to interference from the recall of prior items than is the free recall mechanism

Neural Effects and the Psychophysical Law

THE claim that the true psychophysical law is a power function[1] instead of a logarithmic[2] law has led to a number of misunderstandings about the real significance of Stevens's point of view

Treisman[3] has tried to show that the so-called 'stimulus function' conceived to be both a power function and a logarithmic one His model involves the stimulus function as a relation between the stimulus-level and the level of central neural effects (C), the magnitude of which depends on the stimulus intensity, $C=f(I)$ To scale the sensory magnitude in a 'direct' ratio-scaling procedure the subject is asked to report whether a variable stimulus is greater or less than twice the standard Such an instruction to the subject involves a criterion to be met by the sensory magnitudes, with the scaling procedure leading to fixed ratios between the adjusted and standard stimulus intensities

On this basis, Treisman shows that two criteria for the central neural effects (C) may arise that is, his formulæ (3) $C''/C' = d = 2$ and (5) $C'' - C' = j = \log 2$ Depending on the choice of the 'stimulus function' these criteria can be derived, the first criterion is brought about by a power function and the second one by a logarithmic relation

At this point in his model, Treisman jumps from the subjective magnitudes to the values of the hypothetical central neural effects (C) Whether this is correct is questionable

In other words the criteria can be described as follows The hypothetic central neural effects (C) have to be adjusted until their values show up a ratio of a factor 2 The second criterion asks for central neural effects which show up a difference in magnitude by the amount of log 2 The first criterion seems rather sound in so far as the instruction is also expressed in terms of making the variable stimulus twice the standard Thus, in using this criterion one may hope that the central neural effects (C) are related to sensory magnitudes in at least a proportional way The second criterion, however, demands a constant absolute difference between the central neural effects to be in line with the instruction of doubling the sensory magnitude Since the difference asked for amounts to log 2 in doubling the sensation, it seems as if the central neural effects (C) are logarithmically related to the sensory magnitudes If so, then jumping from sensory magnitudes to the central neural effects is an unwarranted proposition

The second criterion suggested by Treisman holds that the subject is able to compare central neural effects on an absolute scale and to derive conclusions from this comparison with respect to the magnitudes of the sensation If true, the ratio scaling procedure leads to a proportional relation between the neural effect and the logarithm of the stimulus intensity However, this result does not warrant the logarithmical character of the psychophysical function The psychophysical law tries to relate sensory magnitude and stimulus intensity

Thus, the relation between the neural effects and the sensory magnitudes should be taken into account. By the second criterion a proportionality between the neural effects (C) and the logarithm of the sensory magnitudes (S) is assumed, whereas the condition $j = \log 2$ requires an equality $C = \log S$ Insertion of this equality into the 'stimulus function' (formula (4)) $C = h \log I$ leads to a power function relating sensory magnitude and stimulus intensity

In conclusion, the model suggested by Treisman is a valuable one towards solving the problems of matching abilities and ratio production in relation to neural events His 'stimulus function' is a useful concept to operate with if one is interested in information processing in the nervous system However, the 'stimulus function' cannot be taken as representative of the psychophysical relation between sensory magnitude and stimulus intensity

H W HOREMAN

Instituut voor Perceptie Onderzoek,
Insulindelaan 2, Eindhoven,
Netherlands

[1] Stevens, S S , *Amer Sci* , 48, 226 (1960)
[2] Fechner, G T , *Elemente der Psychophysik* (Leipzig, 1860)
[3] Treisman, M , *Nature*, 198 914 (1963)

THE question of the proper empirical basis of the 'psychophysical law' has caused much controversy It has been held that 'indirect' methods of scaling 'sensation', such as cumulating *j n d* 's, lead to log functions, and 'direct' procedures to power functions, and argument has usually been directed to showing that one type of procedure is better than the other, and therefore that one function but not the other, gives the 'correct' measure of sensory magnitude. However, it can be argued that this aim is misconceived[1]. In either type of procedure the subject performs a sensori-motor task under instruction, and what we record, on conventional physical scales, are the stimulus intensities (I) administered, and the responses (R) elicited. These are the data and if we are to have something further to measure we need some model of the intervening processes. Perhaps the simplest model is that which assumes that when a stimulus is presented to the subject it produces a central effect, C, lawfully related to the stimulus intensity, I, and that C functions as a measure of the stimulus, being used to determine the selection of the response, R. C is then related to I by a 'stimulus function', $C = f(I)$, and a corresponding response function or lawful procedure relates it to R. Evidence on the relation of I to R, alone, is insufficient simultaneously to specify both functions; only if an arbitrary or conventional choice of one function is made can the data serve to determine the other. Since numbers do not inhere in events or objects, but are assigned by us in accordance with some rule, our initial specification of one of the functions is equivalent to the choice of a rule for scaling C. If we decide that when a response criterion is reached we will consider that a constant increment (j) has been added to C, the stimulus function found will be logarithmic, if we assume that there has been a constant proportional increase (d) in C, a power function will be given; and this is true whether 'direct' or 'indirect' procedures are used, either law can be derived from either set of data, given the appropriate initial assumptions. Further, it was suggested that C should be taken as a measure we attach to an inferred neural effect of the stimulus.

To these arguments Horeman objects that 'sensory magnitudes' cannot be identified with central neural effects, when the subject is instructed to 'double the apparent sensation' (or some equivalent form of words) he applies this instruction to his sensory magnitudes (S) so that a doubling of S corresponds to an increment of log 2 on the scale $C = h \log I$, and C is then logarithmically related to, not identical with, S. The 'psychophysical law' applies to S, not C, and has the form of Stevens's power function[2].

The difficulties in adding an extra dimension, S, to which the instructions apply literally, and on which the subject operates, can perhaps best be illustrated by a 'thought-experiment'. We suppose we have to investigate not a human subject but an 'automatic light-selector', consisting of a photometer linked to a computer with a programming device attached. Lights of varying brightness are supplied to this apparatus, and from them it selects series of lights in accordance with a programme which is fed into the programming device in English, and translated by it into instructions in machine language which control the working of the computer. When we examine the lights selected we find that they fall into the series 10, 100, 1,000 millilamberts. The question now arises: Does the photometer record millilamberts and the computer select lights separated by a constant ratio of 10, or are log millilamberts recorded and lights selected at a constant interval of 1 log unit? To discover the answer we might open the apparatus and inspect the photometer dial, but we find that it has no scale inscribed. We could, if we wish, now calibrate the photometer, writing against the deflexion produced by the 10-millilambert light '10', or '1', and against that for the next light '100', or '2' and so on. Whichever we do the light-selector will work as well as before, and in no different a way, and we shall have solved our problem, arbitrarily, by the choice of a rule for inscribing numbers on the photometer dial, which rule we choose will determine our system of description, but both systems are equally valid if used consistently.

But now various objections might be raised. Thus it might be argued: "The programme controlling the computer reads: Starting with a light of 10 millilamberts select lights whose brightnesses increase by a ratio of 10'—this indicates that the millilambert scale is being used." But this is a fact about the English programme only: the programming device would give the same machine language translation to the instruction "Starting with a light of 1 log millilambert select brightnesses at intervals of one log unit". In either case the computer would work in the same way to select the same lights. Thus the conventions which make it more likely that the English programme will use millilamberts than log millilamberts, and will ask for a light to be doubled rather than increased by 0.3 log units, are not evidence about the nature of a unique scale used by the photometer. Nevertheless, it might still be argued "the instructions call for brightness to increase by a constant ratio, the selector performs the task set it, therefore we can assume a dimension to which the instructions are applied, and it gives a measure of brightness in millilamberts". If this argument leads the objector to calibrate the photometer to agree with the form of instruction that happens to have been given it will not be any the less true that this is an arbitrary choice, an expression not of empirical compulsion but of sentiment or convenience. If it leads him to conclude that the dimension used is not the essentially ambiguous photometer reading but some unobservable parallel system, this suffers the embarrassment of being highly unparsimonious: it is apparent that the computer and photometer are there, operating, and quite able to account for all selections we observe. If it leads him to expand the sequence $I \to C \to R$ into $I \to C \to S \to R$, then S is either parallel to (with the difficulties above) or part of the selector, in either case we are no better off than before: we must now write three functions, and to do so the available information, given by the relation of R to I, must be spread more thinly. Two functions must arbitrarily be assumed before the data will specify the third, and it is clear that a large number of alternatives will be possible.

The light-selector is at best an analogy, and perhaps a false one, for the human subject in a scaling experiment, but it may demonstrate how far commonly acceptable scientific modes of argument will take us in a case of this sort, and illustrate that unless we are to suppose that the use of the word 'sensation' justifies us in using novel principles of reasoning, there is no good basis for postulating an extra dimension, S, additional to C. It should be noted that the arguments about the nature of the stimulus and response functions hold whatever identification is given to C. The suggestion that C should be taken as a measure of a neural effect rests on our knowledge that the neural apparatus is there, and that we have no reason to doubt that it is adequate to mediate all sensory effects on motor activity.

The argument given here does not imply that there can be no unambiguous criterion for choosing a scale for C—one can be evolved[3]—but that the conventional treatments of scaling data do not provide this. It does not imply that no useful account can be given of the concepts subsumed under 'sensation', but that, despite their name and aim, sensory scaling experiments do not do this. It is not meant to detract from the value of the large body of very able experimentation that has been devoted to these problems by Stevens and others[2], only to develop their interpretation. It is necessarily condensed, but some points are dealt with more fully elsewhere[4].

FORTHCOMING EVENTS

Saturday, December 28

Royal Institution (at 21 Albemarle Street, London, W 1), at 3 p m — Prof Ronald King 'Energy" (First of the One Hundred and Thirty-fourth Course of six lectures adapted to a Juvenile Auditory Further lectures on December 31, January 2, 4, 7 and 9)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Bacteriologist, an Assistant Chemist, and an Assistant Economist—The Secretary, Edinburgh School of Agriculture, West Mains Road, Edinburgh (December 28)

Bacteriologist (with an honours degree or an equivalent qualification and preferably postgraduate experience in microbiology or the biological sciences) in the Central Laboratory of the Milk Marketing Board for Northern Ireland, Belfast, to have special responsibility for the bacteriological aspects of the Board's work, and to assist in the running of the Board's laboratory services generally—The General Manager, Milk Marketing Board for Northern Ireland, 456 Antrim Road, Belfast 15, Northern Ireland (December 31)

Demonstrator in the Department of Botany—The Registrar, University College of Wales, Aberystwyth (December 31)

Junior Lecturer (preferably interested in cytological or physiological aspects of vertebrate reproduction) in Zoology—The Secretary, Medical School of St Bartholomew's Hospital, West Smithfield, London, E C 1 (January 4)

Senior Lecturer in Forensic Medicine at the University of Singapore —The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 4)

Chair of Sociology at the University of Ghana—The Registrar, University of Ghana, P O Box 25, Legon, Accra, or The Assistant Registrar (Overseas), University of Ghana, 15 Gordon Square, London, W C 1 (January 6).

Lecturer in Civil Engineering—The Registrar, The University, Sheffield (January 6)

Lecturer (with a recognized degree in agriculture, or in pure science with agricultural or horticultural experience, and preferably a sound knowledge of tropical crops, with some experience in plant breeding and selection) in the Department of Crop Husbandry and Horticulture, University of Ghana—The Registrar, University of Ghana, P O Box 25, Legon, Accra, or The Assistant Registrar (Overseas), University of Ghana, 15 Gordon Square, London, W C 1 (January 10)

Senior Lecturer and a Lecturer in Mathematics at the University College of Townsville, University of Queensland—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (London and Brisbane, January 10)

Senior Lecturer or Lecturer (with a veterinary science degree or an honours degree in agricultural science with special reference to animal husbandry, and preferably a knowledge in ruminant nutrition and pasture problems) in Animal Husbandry at the Royal College, Nairobi—The Secretary, Inter-University Council for Higner Education Overseas, 29 Woburn Square, London, W C 1 (January 10)

University Lecturer in Pure Mathematics—The Secretary of the Appointments Committee of the Faculty of Mathematics, Arts School, Bene't Street, Cambridge (January 11)

Senior Lecturer in Physical Chemistry at the University of Western Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 15)

Lecturer in Physical Chemistry at the University of Sydney, Australia —The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 16).

Lecturer (with experience and interest in some aspects of plant physiology or biochemistry, preferably at the cell level) in Botany—The Secretary of University Court, The University, Glasgow (January 16)

Central Electricity Generating Board Fellow in Engineering Science, to engage in full-time research on a topic related to the scientific interests of the C E G B in the University Engineering Laboratory, to assist in supervising research students in that Laboratory, and to undertake a limited amount of teaching of undergraduates in the College—The Principal, Hertford College, Oxford (January 17)

Lecturer in Pharmaceutical Chemistry (Physical Chemistry) at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 17)

Lecturer (with an honours degree in some branch of chemistry and if possible the degree of Doctor of Philosophy) in Inorganic Chemistry at the University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (London and Brisbane, January 17)

Lecturer or an Assistant Lecturer in Pure Mathematics—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (January 18).

Lecturer (graduate in science or agriculture) in Agricultural Chemistry at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 24)

Chair of Civil Engineering—The Registrar, The University, Sheffield (January 27)

Chair of Plant Physiology at Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W C 1 (January 27)

Librarian (graduate with professional qualifications), to be in charge of a new college library—The Tutor, New Hall, Silver Street, Cambridge (January 27)

Assistant Lecturer in the Mechanics of Fluids in the Faculty of Science—The Registrar, The University, Manchester 13 (January 31)

Chair of Chemistry, Chair of Physics, Chair of Botany, and Chair of Mathematics at the University College, Dar es Salaam, University of East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 31)

Chair of Natural Philosophy—The Secretary, The University, Aberdeen (January 31)

Chair of Pure Mathematics, Chair of Psychology and Headship of the Department, Chair of Building Technology, and Chair of Sociology—The Registrar, The University, Nottingham (January 31)

Lecturer in Educational Psychology—The Registrar, The University, Manchester 13 (January 31)

Lecturer or Assistant Lecturer in Philosophy at Fourah Bay College, The University College of Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 31)

Lecturers or Assistant Lecturers in Chemistry—The Secretary University of Lancaster, Bailrigg House, Lancaster (January 31)

Lecturer (Grade II) in the Department of Inorganic Chemistry—The Registrar, The University, Senate House, Bristol 2 (February 14)

Professor of Physiology—The Secretary, University College, Galway, Republic of Ireland (February 20)

Foundation Chair of Mathematics (either Pure or Applied) at Wollongong University College—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (February 28)

Assistant Master to teach Mathematics at all levels—The Head Master, Wrekin College, Wellington, Shropshire

Master to teach Physics—The Master, Wellington College, Crowthorne, Berkshire

Research Assistant (graduate with an interest and experience in microbiology, mycology and bacteriology) in the Department of Biological Sciences, to undertake work on the taxonomy, ecology and serology of Actinomycetes—The Registrar, Bradford Institute of Technology, Bradford 7

Research Assistant in the Chemistry Department, for work under Prof R M Barrer on the surface and colloid chemistry of apatite and of materials potentially of interest as dental restoratives—Prof R M Barrer, F R S, Chemistry Department, Imperial College, London, S W 7

Research Assistant (with a good degree in zoology or microbiology, and preferably some experience in electron microscopy) in the Electron Microscope Laboratory—Dr R G Bird, London School of Hygiene and Tropical Medicine, Keppel Street, London, W C 1

Senior Research Fellow (with several years postgraduate experience) in Biochemistry in the Department of Pharmacology—The Secretary Royal Free Hospital School of Medicine (University of London), 8 Hunter Street, London, W C 1

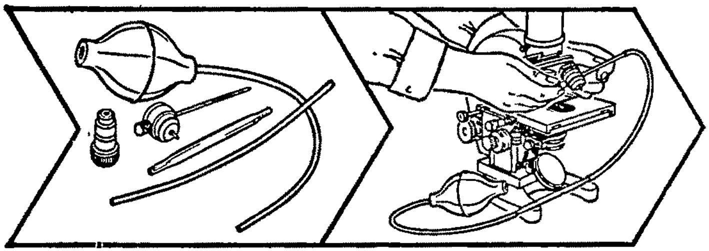
meopta MICROSCOPES ACCLAIMED BY HOSPITALS AND UNIVERSITIES



Monosporic Isolation Equipment

The new equipment, for isolating a small portion of any semi-solid preparation under sterility conditions, consists of a 10×0 30 objective, isolator with capillary for picking up the specimen, and rubber bulb air filter and tubing for ejecting it Meopta monosporic isolation equipment is particularly suitable for use with microscope C36 BI (illustrated), which is available with integral or reflected lighting systems

Send for full details of these and other Meopta microscopes and accessories—noted for their high performance and surprisingly low price.

Admit it:
we're talking sense

We're talking about life assurance We're talking, in fact, about the oldest mutual life office the Society that laid the foundations of life assurance as it is known today The 'Old Equitable', founded two hundred years ago, has this about it

It has no shareholders It pays no commission for the introduction of business This is how life assurance was originally conceived, and in preserving these co-operative principles, the 'Old Equitable' provides life assurance at cost price

The 'Old Equitable' is friendly and helpful, and it does a good job for your money For example, a quarterly payment of £17 12 6 secures a man of 25 an assurance of £3,000 sharing in major profits and payable at death whenever that should occur Such a policy taken out 50 years ago would this year yield over £10,000 on the death of the life assured If you would like to know more about the many kinds of assurance that the 'Old Equitable' offers, please fill in the coupon below

get in touch with the
'OLD EQUITABLE'

APPOINTMENTS VACANT

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Lecturer or Assistant Lecturer in Applied Mathematics in the Department of Mathematics in the Faculty of Science Salary scales Lecturer, £1,250 to £2,150 per annum , Assistant Lecturer, £1,000 to £1,150 per annum , initial salary (at Lecturer grade) and status according to qualifications and experience Membership of the F S S U and Children's Allowance Scheme

Applications should be sent not later than January 15, 1964, to the Registrar, the University, Manchester 13, from whom further particulars and forms of application may be obtained

UNIVERSITY OF LIVERPOOL

RESEARCH ASSISTANT FOR WORK ON AVIAN ANATOMY

Applications are invited for the above appointment in the Department of Veterinary Anatomy, University of Liverpool, with the possibility of taking a higher degree Candidates must be graduates and have either a veterinary qualification or an Honours degree in zoology

Applications, with the name of one referee, should be submitted to the Registrar, University of Liverpool, not later than January 2, 1964, quoting reference number CV/484/N

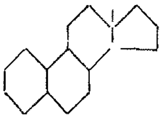
NEW ZEALAND

AGRICULTURE DEPARTMENT

Applications are invited for the undermentioned vacancy Vacancy B13/2/27/3674 , Technical Officer, Ruakura Salary Up to £1,580 a year, depending on qualifications and experience Qualifications desired F I M L T or equivalent with experience in diagnostic, microbiology, serology, and clinical pathology Experience in instructing and supervising junior staff is desirable Preference will be given to a person with knowledge of organisms pathogenic for domestic animals Passages Fares for appointee and his wife and family, if married, will be paid Incidental expenses Up to £35 for a single man and £100 for a married man can be claimed to cover the cost of taking personal effects to New Zealand

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London, S W 1, with whom applications will close on January 17, 1964 Please quote reference B13/2/27/3674 when inquiring

SYNTEX LABORATORIES, INC.



SYNTEX is creating a major research organization in Palo Alto, California, where new laboratories are under construction Applications are invited for the following positions within the group

HEAD OF THE RESEARCH ANALYTICAL DEPARTMENT

The successful applicant will have worked in steroid chemistry and will possess a practical knowledge of current physical methods of analysis, including chromatographic procedures and O R D , U V , I R , and N M R spectroscopy Evidence of exceptional research capability and the ability to initiate and develop research programmes in these areas will be prerequisites to selection The possession of, or ability to rapidly acquire, a specialized knowledge of N M R and mass spectroscopy will be necessary

This is an excellent opportunity for a first-class man to move into a dynamic company

SENIOR DEVELOPMENT CHEMIST

This post calls for a high level of practical experience in development methods, together with a broad knowledge of steroid chemistry The successful applicant will be required to supervise a group of qualified assistants, while the continued rapid growth of the company activities ensures opportunities for promotion to greater responsibilities

Applications, with full particulars should be made to the Vice President in Charge of Research, Syntex S A , Apdo Postal No 2679, Mexico, D F , Mexico

Research in Industry with 'ENGLISH ELECTRIC'

Nelson Research Laboratories, Stafford

A number of interesting vacancies have arisen for Scientists and Engineers to join research teams at our laboratories, which are situated in green belt country two miles from the centre of the town Applicants should possess a good first degree or a higher degree , previous research experience is desirable but not essential Details of the posts are as follows

PHYSICISTS

with experience in semiconductors for
(a) Study of electrical surface effects
(b) Device design, requiring knowledge of diffusion with epitaxial technology (Ref *N*913Z)

PHYSICISTS

with experience in magnetic materials, for investigation of their properties in relation to electrical equipment design (Ref *N*913A)

PHYSICISTS

with interest in plasma physics, hydrodynamics or allied subjects, for experimental work in connection with magnetohydrodynamic generation of electricity (Ref *N*913B)

ELECTRONIC ENGINEERS

to design and develop circuits, particularly in the control of power supply systems (Ref *N*906B)

INSULATION ENGINEERS

with training in physics or chemistry for investigation of gaseous liquid and solid insulation used in electrical equipment (Ref *N*918A)

MECHANICAL ENGINEERS

with mathematical interests for the investigation of problems such as heat transfer and stress analysis (Ref *N*917A)

All these posts offer excellent opportunities, are pensionable and carry salaries commensurate with experience

Please write, quoting appropriate reference number and giving full particulars of qualifications and experience to

Dr. R. J. Benzies, Manager, Nelson Research Laboratories, Room 535, English Electric House, Strand, London, W.C.2.

'ENGLISH ELECTRIC'

DALHOUSIE UNIVERSITY

INSTITUTE OF OCEANOGRAPHY

Applications are invited for three academic posts—in Geophysics, tenable in the Physics Department, in Marine Geology and in Marine Chemistry—within which the appointee will conduct research and undertake a limited amount of formal teaching Appointment will be made at a rank and salary appropriate to qualifications For a recent Ph D the beginning salary is $7,000

Address all correspondence and recommendations to The Director, Institute of Oceanography, Dalhousie University, Halifax, Nova Scotia, Canada

UNIVERSITY OF SASKATCHEWAN

DEPARTMENT OF ANATOMY

Applications are invited for the position of Assistant Professor in Anatomy Salary range $7,000 to $9,300 according to experience Ample opportunities for research in various fields Good research facilities

Apply to chairman of the Department of Anatomy Saskatoon, Sask , Canada

UNIVERSITY OF MANCHESTER

Applications are invited for two posts of Lecturer in Pure Mathematics in the Department of Mathematics in the Faculty of Science Salary scale £1,250 to £2,150 per annum, initial salary according to qualifications and experience Membership of the F S S U and children's allowance scheme

Applications should be sent not later than December 28, 1963, to the Registrar, The University Manchester, 13, from whom further particulars and forms of application may be obtained

UNIVERSITY COLLEGE OF WALES

ABERYSTWYTH

DEPARTMENT OF BOTANY

Applications are invited for the post of Demonstrator in the Department of Botany The salary will be in the range £800 to £900 per annum with membership of the Federated Superannuation System for Universities

Forms of application may be obtained from the Registrar to whom applications should be made by December 31

Harwell

Vacancies for GRADUATES in

PHYSICS
MATHEMATICS
METALLURGY

There are vacancies at Harwell for graduates who are interested in working in one of the following fields

NUCLEAR PHYSICS	Basic research into nuclear structure and reaction mechanisms Objective research on nuclear cross-sections and other data for reactor calculations The comprehensive facilities available include the following accelerators 3 MeV Van de Graaf with nanosecond pulsing, 5 MeV Van de Graaf, 12 MeV Tandem Van de Graaf, 50 MeV Proton Linear Accelerator, 170 MeV Synchrocyclotron and 28 MeV Electron Linear Accelerator producing neutrons from a sub-critical fissile target Research is also carried out on the structure of liquids and solids, using neutron scattering and Mossbauer techniques
SOLID STATE PHYSICS	Basic research into the electronic structure of solids Neutron beams, as well as conventional laboratory techniques, are used in the detailed investigation of magnetic and other solids Primary radiation damage processes in high purity materials are investigated by resonance and optical techniques
THEORETICAL PHYSICS	Research into the theoretical aspects of nuclear, solid state, liquid, and neutron physics problems Research is at present in progress on the structure of the nucleus, nuclear reactions, elementary particles, many body theory of the electron gas and of liquids, magnetism, neutron scattering from solids and liquids, dislocations, radiation damage, atomic cross-sections and phase transitions
MATHEMATICS	Research into numerical approximation, including applications of functional analysis, and related fields, and into non-numerical applications of large computers, especially artificial intelligence Research is at present in progress on non-linear sub-spaces of function spaces, minimization techniques, differential equations, linear algebra, quadrature methods, automatic optimization of computer programmes, and project analysis
METALLURGY	Basic and applied research into the structure and properties of materials used in nuclear energy, including the effects of irradiation

Applicants should possess a First-class or a good Second-class Honours degree in Physics, Mathematics or Metallurgy, and should preferably have had postgraduate research experience at a university or similar institution

Depending upon age and experience, the initial salary for these posts will be within the range £850 to £1,900 (with the possibility of salaries within the range £2,030 to £2,835 for exceptionally well qualified scientists)

Housing

Superannuation Scheme

If you would like further details please write to Personnel Department (A 5047/34), Atomic Energy Research Establishment, Harwell, Berks

---

IMPERIAL COLLEGE

Research Assistant required to take day to day charge of a research project on the mechanical properties of metals and non-metals Good honours degree in any branch of technology and some research experience essential Commencing salary up to £1 370 per annum according to qualifications and experience, plus £60 London allowance, family allowances and F S S U benefits

Apply in writing to Dr R D Hoyle, Mechanical Engineering Department, Imperial College, London, S W 7

UNITED BIRMINGHAM HOSPITALS

CHILDREN'S HOSPITAL, LADYWOOD ROAD, BIRMINGHAM, 16

SENIOR GRADE BIOCHEMIST

Required for Biochemistry Department Experience in paediatric biochemistry or micro-analysis not essential The person appointed will be encouraged to specialize in some aspect of the subject Good facilities are available for biochemical investigations in cardiac surgery

Apply, giving two referees, to Dr D N Raine

UNIVERSITY OF LONDON

CHAIR OF PLANT PHYSIOLOGY AT IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

The Senate invite applications for the Chair of Plant Physiology at the Imperial College of Science and Technology (salary not less than £2,900 a year plus £100 London allowance)

Applications (ten copies), must be received not later than January 27, 1964, by the Academic Registrar, University of London, Senate House, W C 1, from whom further particulars may be obtained.

Harwell

Irradiation of Solids

We have vacancies in the Irradiation Branch of the Harwell Metallurgy Division for Physicists and Metallurgists with interests in the Solid State field

Successful candidates will become members of an active group studying the behaviour of irradiated solids The problems call for an understanding of the formation of atomic crystal defects and their behaviour and influence upon the macroscopic properties of the solid experience of irradiation behaviour is not, in itself, essential Every encouragement will be given for original research for which there are excellent facilities, including a wide range of modern equipment, e g , high resolution electron microscope, micro-probe-analysers and accelerators

Applicants should possess a First-class or a good Second-class Honours Degree in Physics or Metallurgy Depending upon age and experience, the initial salaries for these posts will be within the scales

SCIENTIFIC OFFICER £850–£1,405 p.a.

SENIOR SCIENTIFIC OFFICER £1,540–£1,900 p.a.

Authority Housing : Superannuation Scheme

Please send a POSTCARD for application forms to PERSONNEL DEPARTMENT (A 5044), ATOMIC ENERGY RESEARCH ESTABLISHMENT, HARWELL, BERKS

AEI

THEORETICAL PHYSICIST

The AEI RESEARCH LABORATORY, RUGBY, requires a theoretical physicist for work in the field of solid state physics, in collaboration with a group of experimental physicists engaged on problems associated with semiconductor devices, with lasers and with thermoelectric applications

Applicants should have a good honours degree or Ph D, together with postgraduate experience in theoretical physics and a keen interest in the application of scientific theory to the solution of problems of industrial importance Applications should be addressed to

Director of A.E.I. Research Laboratory,
Rugby, Warwickshire.

AEI
RESEARCH

UNIVERSITY OF READING

DEPARTMENT OF PHYSICS

Applications are invited for a Lectureship in Experimental Physics, the appointment to date from October 1, 1964, or earlier if possible

Further particulars may be obtained from the Registrar (Room 22, O R B), The University, Reading, by whom applications should be received not later than January 15, 1964 It is possible that more than one appointment will be made.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Assistant Lecturer in the Mechanics of Fluids in the Faculty of Science The salary scale is as follows £1,000 to £1,150 per annum Membership of F S S U and children's allowance scheme

Applications should be sent not later than January 31, 1964, to the Registrar, The University, Manchester, 13, from whom further particulars and forms of application may be obtained

---

AUSTRALIA

UNIVERSITY OF NEW SOUTH WALES

invites applications for appointment to the position of

ASSOCIATE PROFESSOR SCHOOL OF ELECTRICAL ENGINEERING

Salary will be not less than £A3,455 per annum (subject to cost of living adjustments) Applicants must hold a higher degree and preference will be given to specialists in the field of power engineering An interest and experience in energy conversion, the optimization problems of the power industry and the control of power are desirable The successful applicant will be responsible to the Head of the School, Professor R E Vowels, for the development of research and graduate courses in the power field The School of Electrical Engineering has recently moved to a new building on the Kensington site Further details may be obtained from the Head of the School of Electrical Engineering, Professor R E Vowels Subject to the consent of the University Council, Professors may undertake a limited amount of higher consultative work The University reserves the right to fill the position by invitation

Prospective applicants should write to the Agent-General for New South Wales, 56-57 Strand, London, W C 2, for details of conditions of appointment, including travel arrangements, superannuation, study leave, housing scheme Four copies of applications should be forwarded together with the names of three referees and a recent photograph to reach the Agent-General before January 31, 1964 One typed copy of the application should be forwarded by airmail to the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N S W , Australia, to reach there before the abovementioned date

---

UNIVERSITY OF QUEENSLAND

UNIVERSITY COLLEGE OF TOWNSVILLE

The University invites applications for the positions of

SENIOR LECTURER AND LECTURER IN MATHEMATICS

in the University College of Townsville These are new posts to be established in 1964 The University College is situated in Queensland's second largest city, and has entered on a period of rapid development Full degree courses will be available in a number of Faculties in 1964 and further development and expansion of the College is planned for the immediate future Applicants should have an honours degree in mathematics and preferably some postgraduate study, their special field of interest may be in Pure Mathematics or Applied Mathematics The salary range for Senior Lecturer is £A2,670 by £A100 (4) by £A130 (1) to £A3,200 and for Lecturer £A1,850 by £A100 (7) to £A2,550 In addition a northern allowance of £A30 per annum will be payable The University provides F S S U type superannuation, housing assistance, study leave and travel grants

Additional information and application forms will be supplied upon request to the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 Applications close in London and Brisbane on January 10, 1964

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

CHEMISTRY DEPARTMENT

Applications are invited for a Research Assistantship for work under Prof R M Barrer on the surface and colloid chemistry of apatite and of materials potentially of interest as dental restoratives Salary £1,000, rising by £50 per annum over a five-year period, plus £60 London allowance, family allowances, and F S S U benefits

Applications, giving full academic background and naming two referees, should be sent to Prof R M Barrer, F R S , Chemistry Dept , Imperial College, Imperial Institute Road, London, S W 7

ORGANIC CHEMISTRY

There is a vacancy in the Research Laboratories of Vitamins Limited for work in the field of natural products Applicants should be of good degree standard or G R I C , preferably with some experience, essentially with a high standard of knowledge and interest in their subject

Applications, giving brief details of career to date, should be sent to Assistant Personnel Manager, Vitamins Limited, Upper Mall, London, W 6

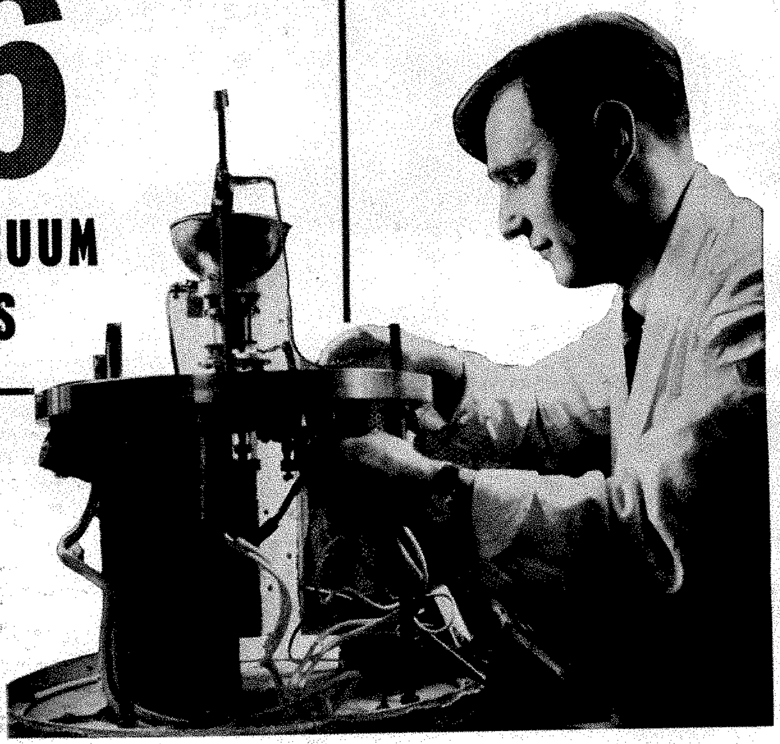
NEW VACUUM PRODUCTS



In 1963 we added 36 new vacuum products to our range . . . the sign of a progressive research and development organisation. In 1964 this already heavy programme will be expanded . . . why not visit our stand for a preview ?

The illustration shows a researcher in our Surface Physics Laboratory engaged on studies of contamination of ultra high vacuum systems. The results of his work, and that of his many colleagues in our extensive research laboratories, will contribute to the design of some of the equipment which will be exhibited at the 1964 exhibition.

SOME NEW SPEEDIVAC PRODUCTS INTRODUCED IN 1963

ROTARY PUMPS
- MODEL ES35
- MODEL ED35

VAPOUR PUMPS
- MODEL EO2 OIL PUMP
- DCB2 PELTIER BAFFLE

INSTRUMENTS
- SERIES 8 PIRANI GAUGE
- COMBINED ION-PIRANI GAUGE
- OMEGATRON MASS SPECTROMETER
- FILM THICKNESS MONITORS

ACCESSORIES
- NEW SOLDERLESS PIPELINE COUPLINGS
- VITON 'O' RINGS

PLANT
- 6" ULTRA HIGH VACUUM PUMPING GROUPS
- WATT-TYPE MICRO STILL
- PEARSE TISSUE DRYER
- HIGH TEMPERATURE FURNACE
- MODEL 19A8 MICRO-CIRCUIT COATER

ANNUAL EXHIBITION OF SCIENTIFIC INSTRUMENTS AND APPARATUS

PHYSICS DEPARTMENTAL LIBRARY

ADMINISTRATION OF EDUCATION AND CIVIL SCIENCE IN BRITAIN

WHILE the main proposal of the Trend Report* for a fundamental reorganization of the Department of Scientific and Industrial Research is logical and has much to commend it in practice, when the Committee examines the position and functions of the Minister for Science, its proposals are more open to question. Those proposals are intended to discharge the second and third parts of the Committee's terms of reference: to consider the arrangements for determining with appropriate advice the relative importance in the national interest of the claims on the Exchequer for promoting civil scientific research in the various fields and the changes that may be needed in the arrangements for financing the agencies concerned and accounting for their expenditure. The Committee seems to have been content, however, to accept a view of the functions of the Lord President of the Council in regard to intelligence and research put forward in the Haldane Report without any searching enquiry as to the magnitude of subsequent changes in the relations between science and Government, or an expressed coherent view as to the part science and technology play in the State to-day. It admits, indeed, that the division of functions should be kept under regular review and, in particular, that the whole administrative structure should be scrutinized regularly and frequently by an authoritative body. Another generation and a half should not be allowed to pass without such a review, but it seems a little naive to suggest that an internal body such as the new Advisory Council could contribute significantly in this respect.

The structure proposed in the Trend Report is based on the principle of a separate autonomous agency for the conduct of research and the pattern of such agencies is to be rearranged to cover the whole field of civil scientific activity with effective supervision by the Minister for Science. Neither he nor his advisers, however, should seek to influence the scientific judgment of the research agencies acting within their respective terms of reference and within the resources made available to them. The tradition that the Minister for Science does not intervene in the exercise by the Research Councils of scientific judgement within their own fields is fully endorsed.

On the other hand, the Trend Committee believes that the Minister should be given wider powers to enable him to play a more positive and effective part than hitherto in promoting scientific research and development. This includes, first, the encouragement of conditions in which research can flourish and its results be put rapidly to use. It is here that the recommendations of the Trend Committee impinge on those of the Robbins Committee†, and the Trend Committee considers that there would be obvious advantages in vesting responsibility for higher education and responsibility for civil scientific policy in one and the same Minister.

Leaving that point for the moment, the Committee recommends that the Minister for Science should assume, and discharge to Parliament, the responsibility for assessing the financial requirements of the agencies, for settling with the Treasury the funds to be made available for civil research and development and for allocating these funds among the agencies. In the view that it urges in this Report, the Trend Committee regards it as essential that the Vote arrangements should enable the Minister to exercise real and effective supervision over the whole field, but they should not be such as to involve the individual agencies in a greater degree of accounting responsibility than is compatible with the freedom of action implicit in the concept of a grant-in-aid. The Minister should also assume general responsibility for keeping the whole field of scientific research and development under continuous review, to ensure that deficiencies are made good, that unnecessary duplication is avoided and that the broad deployment of effort over the whole field is in accordance with the national interest.

While here the Minister would have the assistance of the reconstituted Advisory Council, what is proposed represents a fundamental break from the negative attitude which has hitherto characterized the Minister for Science. A more positive attitude is also advocated in the recommendation that would make the Minister responsible for the Government's relations with learned bodies in the field of scientific research, particularly the Council of the Royal Society, and also for the Government's international relations in scientific matters, including the appointment and control of scientific attachés. This last-mentioned aspect is a more appropriate and logical arrangement than that which has prevailed in the past, but, taken together the proposals represent a very considerable increase in responsibilities for the Minister for Science. Even if he is divested of all extraneous responsibilities it is legitimate to ask whether it is sound to concentrate virtually all the responsibilities for science in a single Ministry.

This question is not examined by the Trend Committee nor does that body consider the strengthening of the provisions for scientific advice and research within the various Government departments. Obviously, such departments as the Post Office and the Ministry of Defence cannot function without effective means for handling scientific matters internally. The appointment of a director of Research and Development in the Ministry of Public Building and Works and the Trend Committee's own observations regarding the Ministry of Transport and the Road Research Laboratory show that the Committee was fully aware that there may be other departments which would benefit by arrangements to facilitate more effective contact with science It would seem logical that the Minister for Science and his Advisory Council should have advisory responsibilities in science to the Cabinet in general as well as to the individual departments

---

* *Committee of Enquiry into the Organization of Civil Science*. Pp. 59. (Cmnd. 2171.) (London: H.M.S.O., 1963.) 4s. net. (See also *Nature*, 200, 1029, 1963.)

† *Committee on Higher Education. Higher Education*. Report of the Committee appointed by the Prime Minister under the Chairmanship of Lord Robbins. Pp. xvi+335. (Cmnd. 2154.) (London: H.M.S.O., 1963.) 15s. net. (See also *Nature*, 200, 925, 1963.)

Is it then practical to link responsibility for higher education with responsibility for civil science? The Robbins Committee proposed to place the Research Councils under a Minister for Arts and Science, along with the University Grants Committee and other autonomous State-supported activities administered on similar principles The Robbins Committee was agreed, in particular, that the colleges of advanced technology should be granted the status of technological universities—a recommendation that the Government has already accepted—and that, accordingly, these institutions should be administered on the grants committee principle Since the Robbins Committee had been informed in evidence that the Treasury would not feel it appropriate to assume responsibility for additional institutions, a change in ministerial responsibility is obviously involved, unless the two sets of institutions are to be the responsibility of different Ministers, with obvious detriment to the hope of unified policy and the disappearance of differentiation

The Robbins Committee, for various reasons given in the Report, did not view with favour giving responsibility for the University Grants Committee to a non-departmental Minister, nor was the majority in favour of placing all responsibility for education on one Minister It considered that the area of responsibility would be too wide and that the methods and problems of higher education differed so considerably from the methods and problems of education in the schools as to call for recognition of their differences in the articulation of the organization of Government The Robbins Committee did not share the fears that many university teachers have expressed as to the effect of placing the University Grants Committee under the Minister of Education, but it attached much weight to the concern of the main institutions of higher education with the preservation and advancement of knowledge It is this organic connexion of the universities with other forms of organized research that led it to suggest that they should be linked with the Research Councils and the Arts Council in the allocation of ministerial responsibility

The Ministry for Arts and Science, creation of which is recommended by the majority, would not, however, be responsible for the work of the non-autonomous sector of further education in the technical and other colleges of further education However, advanced work in these institutions would be related to that in the autonomous institutions through the creation of a new Council for National Academic Awards, with the power to award degrees For Scottish institutions, the Committee recommends a special relationship between the new Minister and the Secretary of State for Scotland. The prime responsibility for co-ordination over the whole field of education would rest with the three Ministers and their departments, advised on specific questions by national advisory bodies, but the Robbins Committee also recommends the establishment of a small Consultative Council to which Ministers can remit questions concerned with higher education as a whole as well as its relations with the schools

It is obvious from the argument of the Robbins Report that a real stumbling block to a single Minister of Education is the special position of Scottish institutions, and, though this is not mentioned, the sensitivity or hypersensitivity of some sections of opinion in Scotland. That manifestly must be taken into account, however irrational some of its manifestations may appear, if a workable scheme is to be devised, nor is it disregarded by Mr H C Shearman in the "Note of Reservation" in which he sets forth his reasons for preferring a single Minister of Education with one or two Ministers of State to assist him This Minister would take over the present sphere of responsibility of the Minister of Education and that of the Chancellor of the Exchequer for the University Grants Committee and possibly some of the other functions suggested by the majority of the Robbins Committee (Mr. Shearman does not specify research), but he would be at the head of a new department for which a forward-looking outlook might be expected He would presumably adopt the administration styles appropriate to the different parts of the wide field which he would be called on to serve, and devolution should be the keynote of his Ministry

Here Mr Shearman strikes the right note and one that should characterize any form of Ministerial responsibility which may be finally adopted in respect of either education or scientific research The Ministry—or Ministries—should be forward-looking and in function and structure appropriate to the purpose to be served Furthermore, it will be noted that one reason why Mr Shearman prefers to see a single Ministry of Education is that he wishes to see the universities providing the leadership and inspiration that they are uniquely qualified to give The chosen arrangements must provide for this leadership as well as foster the sense of common purpose and continuity which all members of the Robbins Committee alike desiderate, and here Mr Shearman in particular refers to the importance of associating the resources, experience and goodwill of the local education authorities

The arrangement preferred by Mr Shearman is very similar to that advocated in a Bow Group pamphlet by R Smith and R Eddison, *Talent for Tomorrow* (*Nature*, 200, 1162, 1963), whereas his colleagues favour rather the type of structure proposed by a Fabian Group in a pamphlet, *The Structure of Higher Education* (*Nature*, 194, 802, 1962), which was submitted in evidence to the Robbins Committee, but which the Bow Group explicitly rejects The need for greater integration in the administration of research leads the Bow Group instead to favour a single ministry responsible for both education and research The Bow Group suggests accordingly a Minister of Education and Research, advised by an Honorary Council on Higher Education and supported by separate Councils for Technological and Commercial Education and for Professional Education, including teacher training The Minister would also be provided with common services in the form of a statistical office, an educational building office and an educational research centre However, while the University Grants Committee would be responsible directly to the Minister, he would have under him two Ministers of State, one for schools and further education covering the present branches of the Ministry of Education for England and Wales, and the other for science and research, to whom the existing Research Councils would be responsible

Such an arrangement could take care of the proposals of the Trend Committee reporting the Research Councils and might involve fewer difficulties than the precise arrangement proposed by the Robbins Committee As regards the size of the Ministry, it would not appear *prima facie* to be larger than the new Ministry of Defence Its efficiency would depend very largely on the effectiveness of the arrangements made for devolution of authority wherever possible as well as for greater liaison between institutions of various kinds from the local level upwards If the Bow Group can argue with reason that, from the point of view of national needs, the greatest single problem in scientific and technological research to-day is that of liaison between the universities and the newer centres of research, such as the Atomic Energy Authority and other Government establishments, the research associations and industrial research laboratories, it is not only in research that improved communications are required

The vital point is that the administrative arrangement should be chosen to serve the specific purposes needed and not the convenience or prestige of a particular political clique or established interest, and this should be demonstrably seen to obtain Its effectiveness will of course depend also on the character and ability of the men chosen to fill the designated posts, but beyond this it will depend also on the understanding and support of their Cabinet colleagues Effective national policy in higher education and in science is not solely a matter of appropriate administrative arrangements or of the staffing of one or even two departments It depends on adjustments and understanding at many levels from the Cabinet downwards on the ability of Cabinet ministers in general to recognize the significance of the arguments which a Minister of Education or for Science brings forward, and also on the capacity of the Departments themselves to appreciate the bearing of science and technology on their own work No Ministry for Science is likely to prove fully effective unless in many of the Departments there are scientific advisers of high standing and supported by considerable sections able to make full use of new knowledge and new methods Nor should it be forgotten that the shaping of the Government organization to meet the tasks of to-day means also equipping it at all levels to utilize the new tools of management which the computor and other technical advances have placed in its hands Even if a prime responsibility in this sphere continues to rest with the Operations and Methods Division of the Treasury, it only demonstrates that the Treasury itself will need to be in close touch with the new knowledge thrown up continuously under the Minister for Science

There are indeed some signs that this is already being done The establishment in October of a Centre for Administrative Studies within the Civil Service is one sign of new thinking So is the creation of the new post of Secretary of State for Industry, Trade and Regional Development and linking with it the Presidency of the Board of Trade, but much more will be required if the Government structure throughout is to be geared to meet the challenge of what Prof Colin Cherry most aptly termed the "incipient revolution" (*Nature*, 200, 308, 1963) The leader of the Opposition, Mr Harold Wilson, has also shown himself well aware of the challenge, and if neither the Government nor the Opposition has as yet indicated at all precisely how it proposes to meet the challenge on administrative requirements, there is little that need keep political parties apart. It is a valid test of the sincerity of both political parties in their professed support for science and for education whether or not they are prepared to drop party political arguments sufficiently to ensure that, during the short period of life that remains to the present Parliament, the necessary administrative measures are put through to provide a structure which is adequate to serve the needs of the nation in respect of science and of education in the critical years ahead

Nor is the form of the structure required tied too closely to some of the decisions which are most difficult or may require further consideration It does not depend, for example, on decisions regarding the future of the research associations and the stimulation of co-operative industrial research Nor does it depend on the precise location and status of the teacher training colleges, or again on the location of the research stations of the Department of Scientific and Industrial Research, which certainly merits fuller consideration than the Trend Committee proposes for all but two of them On balance, a single Ministry for Science and Education appears to be proposed on the grounds of flexibility as well as avoiding certain difficulties which the Trend Committee and the Robbins Committee alike admit It might also help to minimize the proliferation of committees, under the University Grants Committee proposed by the Robbins Committee, but which has been the subject of some adverse comment It should certainly favour the placing of the colleges of advanced technology on the same footing as the universities, though here a more generous policy than that which the Bow Group contemplates is essential and more in line with that proposed by the Robbins Committee Within the one Ministry, moreover, it should be easier to work out a satisfactory policy for converting the teachers' training colleges into Colleges of Education while securing the full support and understanding of the universities and the local education authorities alike Adequate devolution, understanding and co-operation at all levels are vital, and it is at least possible that this would be facilitated by association of responsibility for science and for education within the one ministry Industry, at least, is unlikely to forget, as a Ministry of Higher Education might, that education is whole, and that the primary and secondary levels are fully as important as the higher levels

If these, then, are the essential needs that the new administrative arrangements must serve it must not be forgotten that there is also an essential task of public education that has to proceed while the detailed arrangements are being worked out and the legislative steps taken This is indispensable if the new structure is to be used effectively and if public support is to be forthcoming for the vast expenditure that is involved, whatever differences in the scale proposed that might exist between the political parties It is relevant, too, if the new Minister or Ministers are to be sure of firm support when their financial proposals are placed before their colleagues in the Cabinet No differences of opinion as to particular details of the recommendations of the Trend Committee or the Robbins Committee should be allowed to hinder the swift formulation of definite proposals for an adequate ministerial and administrative structure to serve the needs envisaged alike in education and in civil science, or to impede the informed discussions of the many difficult and complex issues involved Prompt action and imaginative and forward thinking are imperative, alike in dealing with long-term problems as in dealing with the short-term emergency arising out of the 'bulge' over which the Robbins Report perhaps passes too cursorily

HEALTH IN THE TROPICS

Tropical Health

A Report on a Study of Needs and Resources Pp xxxi+540+9 plates (Washington, D C Division of Medical Sciences, National Academy of Sciences—National Research Council, 1962) 6 50 dollars

THIS volume is published by the U S National Academy of Sciences, National Research Council, as a report sponsored by the U S Army Medical Research and Development Command, the National Institutes of Health, U S Public Health Service and the Rockefeller Foundation

The main objectives of the survey, which was first conceived by the American Society of Tropical Medicine and Hygiene in 1954, were to evaluate the important problems of medicine and hygiene relevant to the future development of the tropics, and to define the resources and research needs as a basis for recommendations regarding the future activities of the United States in these fields

The geographical areas examined were (1) Caribbean, Central and South America, (2) Africa, (3) South West Asia, (4) South Central and South East Asia, (5) Oceania One hundred and sixty-nine countries and territories were included in the survey

So far as possible data covering the period 1954–58 were collected and presented on a regional basis and not in terms of individual countries or political groups The survey was restricted to the most significant public health problems and diseases in the foregoing geographical areas

The subjects investigated were infectious diseases, nutritional diseases, tropical physiology and climatology, environmental hygiene and the zoonoses and other diseases of domestic animals Chronic and metabolic diseases (other than those related to nutrition) were excluded The work finally concerned 34 human conditions ("the great diseases of the tropics") These were considered in four categories diseases of high endemicity, diseases of relatively low endemicity but potentially great because of possible epidemic character, diseases of relatively low endemicity but high mortality or serious complications, new diseases concerning which present knowledge is limited, but which appear to be of considerable health importance

An examination was also made of significant diseases of domestic animals in tropical and sub-tropical areas and of human and animal tropical biometeorology (included in the section on "Research Needs")

Part 1 of the book is concerned with the significant human diseases The difficulties involved in analysing the data were immense, and the authors freely recognize the shortcomings of some of their conclusions which were based on inadequate and inaccurate information provided from underdeveloped areas in which professional personnel was in desperately short supply Unfortunately, except on certain specific points, information was not obtained from mainland China The lack of international uniformity in the notification of diseases was an important source of unavoidable error For example, only five diseases (yellow fever, cholera, plague, typhus and smallpox) were notifiable in all 169 countries and territories of the survey

The four categories of disease are discussed in separate chapters, each condition in terms of distribution, incidence and prevalence in the major geographical areas, morbidity and mortality and public health importance Control is briefly discussed

The first 10 diseases of importance to public health in the five geographical survey areas were tuberculosis, malaria, influenza, nutritional deficiencies (excluding kwashiorkor), cholera, bacillary dysentery pneumonia, measles, whooping cough and amœbic dysentery Tuberculosis, influenza, malaria and pneumonia were among the first ten in the entire survey area Only three of these (malaria, cholera and amœbic dysentery) belong to the classical 'tropical' diseases Only four "have not been demonstrated to be controllable by known means", namely schistosomiasis, leptospirosis, certain arthropod-borne viruses and measles

Part 2 covers significant diseases of domestic animals in tropical and sub-tropical areas An attempt was made to evaluate the importance of diseases of animals in human health problems in terms of zoonoses and protein nutrition Sources of information were generally poor, probably because, in general, veterinary services and facilities for training veterinarians were lamentably deficient On the 23 important diseases of domestic animals studied only one (sweating sickness of cattle) was without known methods of control and prevention The percentage of total budgets expended in veterinary services in the countries investigated was considerably less than that appropriated for health services

Part 3 contains information concerning the numbers of medical and associated personnel, expenditure on health services, numbers and types of hospitals and clinics, and the preventive medical programmes in the survey countries There was serious lack of staff of all categories and of hospital beds and clinics Health expenditure averaged 5–6 per cent of the total budget in most areas which provided reliable relevant figures

Preventive programmes concerned especially immunization against smallpox, typhoid, yellow fever, cholera diphtheria and tuberculosis These varied widely in magnitude and geographical extent More than 500 million vaccinations for smallpox, 95 million for tuberculosis (BCG), 52 million for cholera, 46 million for yellow fever and 27 million for typhoid were performed in the total survey area in the period 1954–58

Data regarding medical missions and medical organizations set up by American corporations working in the tropics indicated that these bodies contributed significantly to medical care and preventive operations in the tropics

Information on water supplies and sewerage systems in the areas of the survey was largely deficient In the Caribbean and Central and South America, which is the most materially developed area surveyed, 39 per cent of the population lacked piped water, the deficiencies being most evident in communities of fewer than 10,000 inhabitants Sewers were non-existent in most rural communities

The impact of disease and the low living standards of tropical populations on the internal economy of the United States was examined in terms of material and strategic interests including foreign trade, market potentials, etc Natural increase in population resulting from successful reduction of morbidity and mortality might be significant unless economy improves in proportion, expected increase in individual capacity for work associated with improvement in health may be an important factor in this balance

Movements of individuals and populations arising from travel, migration, religious pilgrimages, socio-economic development, etc , have important bearings on the distribution and activity of disease processes There are many such examples of the dissemination of disease in war and peace

International sanitary regulations have markedly limited the distribution of the quarantinable diseases, but many 'tropical' diseases which constitute risks to the community or the individual, or both, may still be imported or exported This challenge must be met, especially in view of the speed and frequency of modern travel (Its importance in Europe was recently the subject for discussion at a meeting of representatives of the European schools of tropical medicine held in London and Liverpool)

The practical problems of the United States are discussed in this respect At present, Americans travelling to the tropics are mainly at risk in the Caribbean and Central and South America Increasing interests in the other areas will mean increasing exposure to health risks

Parts 5 and 6 of the report contain surveys of research programmes in tropical problems in progress in the United States and elsewhere, sponsored by the United States and other Governments and organizations

The teaching of tropical medicine and hygiene and opportunities available for training in the United States medical schools and in foreign institutions are summarized and discussed On the whole, incentives and career opportunities in the field of tropical medicine are lacking in the United States

There has been little recent expansion of interest in tropical medicine in the United States The number of workers involved is "such a small fraction of the total professional and scientific personnel engaged in medical and biological sciences that any future expansion in personnel should not constitute any strain on total manpower needs over the next decade"

The remainder of the report deals with an analysis of research needs in human and veterinary medicine in the tropics, based on written opinions obtained from advisers in the various fields Thirty-one human diseases and ten veterinary problems are discussed

Most of the comments made by the authors are self-evident and readily acceptable A series of recommendations is made by the Advisory Committee These include (1) The contribution of the United States to international effort against tropical disease could best be channelled through a national programme for research in tropical health, developed by an advisory organization within the National Research Council (2) Grants should be available for approved foreign institutions to support programmes of research and training in tropical health (3) More effort is recommended to stimulate interest in medical schools at undergraduate and post-graduate levels which should include overseas programmes and tropical field studies (4) The World Health Organization should be invited to intensify its statistical coverage of tropical health, possibly with increased support by the United States (5) The economic aspects of tropical disease should receive closer study, and tropical veterinary education and research should be expanded, particularly in Africa and South East Asia

There are numerous text figures and nine plates demonstrating in maps, with the usual limitations, the tropical world distribution of the major diseases These maps are beautifully drawn and presented, which makes it all the more the pity that the American Geographical Society of New York, which permitted their publication, should have consistently misplaced Surinam and British Guiana

A remarkable amount of well-collated and clearly presented information is contained in this report, which constitutes a valuable reference volume for workers engaged in the research and field problems of tropical health The Appendix detailing the needs for research contains many comments and suggestions which are at once acceptable and familiar to those concerned with tropical problems There is little that is new Omissions were probably determined by the limits within which the survey had to be confined The material published appears to have been decided by the volume of the individual contributions from consultants, and this has led to some imbalance in certain fields, particularly in biometeorology, which appears over-emphasized The almost complete omission of hæmatological and genetic aspects of tropical life and disease is unfortunate

The absence of an index is a disadvantage

However, this is undoubtedly a remarkable and comprehensive report Its recommendations are sound and should be investigated by other Governments concerned in helping developing countries

B G MAEGRAITH

THE DEVELOPMENT OF HISTOCHEMISTRY

Enzyme Histochemistry and Its Application in the Study of Neoplasms

By M S Burstone Pp xii + 621 (Figures) (New York and London Academic Press, 1962) 160*s* 6*d*

AT the present moment, histochemistry is suffering from a wave of popularity Although it is delightful that the subject has been taken up so enthusiastically, it is becoming a little difficult to know how it should be defined This is not to decry the various facets which are becoming disclosed by different workers but to make two pleas first, that if it bears a chemical connotation, at least it should be a science, secondly, that since it relates to tissue its methods should preserve histological structure

Thus there is a view, to which I contribute, that histochemistry is concerned with visualizing cellular chemistry, that it is an extension of biochemistry which can be performed on histologically acceptable sections, and that it has already a certain amount of scientific information which is related to the special conditions concerned with the chemistry of intact sections There is another view that it is predominantly an extension of histological staining, in which the stains have a rational, chemical basis and hence may be indicative, but nothing more, of the chemical activity of the tissue Either way, a professional histochemist tends to study a new work on his subject with some anxiety to ensure that, whatever the views of the author, the work will advance this new subject and not lay it open to ridicule

Dr Burstone is a distinguished histochemist, who has contributed considerably to the histochemical armamentarium As might have been expected, his chapter on proteolytic enzymes, in particular his discussion of aminopeptidase, on which he has done outstanding work, is of real value, of only less importance is his section on cytochrome oxidase, which his own studies have made readily susceptible to histochemical investigation He seems to see histochemical progress as limited solely by the lack of suitable substrates and, consequently, much of the book is devoted to methods by which the newer substrates may be synthesized Although I sympathize with this view, I wonder if this is, indeed, histochemistry For example How many histochemists will be advanced by knowing the X-ray diagram of various naphthol *AS* compounds (pp 78, 79, 80), or the fact that the first aryl glycoside was synthesized in 1879, or will be helped by the chart (IX, p 128) of a multitude of "azine type dyes" which are figured but not even named ? The organic chemistry seems too abstruse for histochemists and on occasion it is even misleading If he succeeds in exciting histochemists to synthesize their own reagents, without training them first in analytical methods for proving the purity of their products, he is indeed liable to spread alarm and confusion

Unfortunately, the book may be criticized on many counts The language is slovenly and often confusing, there is too much qualitative reporting of the "one says this although another disagrees" type, without analysing the contentions and the evidence underlying them, too often a surprising fact is reported without a reference to the source being given But most serious of all are, first, the lack of critical standards for assessing the histochemistry and, secondly, either an apparently total ignorance of tissue biochemistry, or a refusal to relate histochemical findings to those of the biochemists It may be that the biochemical evidence is erroneous, but it would be comforting to have an explanation of how the error arose and how histochemistry has avoided it For example, in the discussion of acid phosphatase, the whole point of de Duve's work on lysosomes has been either missed or ignored, if the latter, then it would have been illuminating to have known on what grounds it was discarded. One is, however, forced to suspect the former. Holt's analysis and modification of the metal-salt method have been misunderstood, and Burstone's obsession about the need to "eliminate spurious staining" would be set to rest if he recognized the value of controls in histochemistry. But even more startling is his insistence on fixation for even this enzyme. Fixation with calcium formol is recommended on p. 207, although formaldehyde is listed among the inactivators of acid phosphatase on pp. 213-215, 218. Even more surprising is the recommendation (p. 207) of a method involving fixation in acetone and embedding in paraffin wax which has been estimated, in another recent text-book of histochemistry, to produce as much as 90 per cent loss of this enzyme. Indeed, there is justification, from this sort of histochemistry, for the jibes that the subject is nothing more than "histo-cookery" or "histo-alchemy".

Burstone's major contribution to histochemistry has been in relation to the azo-dye coupling reactions. He has synthesized and tested many compounds which are likely to be useful. It was to be hoped that his histochemical understanding would have matched his organic chemistry. One of the main worries about these coupling reactions is whether appreciable diffusion of the components or even of the complete dye can occur, so giving rise to spurious localizations. In part, this depends on the 'substantivity' of the dye. On p. 138, Burstone gives a correct definition of this concept as applied in the dye-stuff industry, but proceeds to so modify it for histochemistry as to render it valueless. He then proceeds to argue (on p. 140) apparently by polemic alone, that the naphthol which is released by enzymatic reaction within the tissue binds to the tissue component from which it is released.

Although he is aware of the dangers of diffusion artefact, which could be very severe if the coupling reaction is not extremely fast, he admits he has no scientifically acceptable evidence and offers only pious hopes (p. 95). "With an azo-dye technique the potential qualities of naphthol may be nullified if the coupling with the diazonium salt does not take place promptly. Although there is no actual knowledge about the submicroscopic nature of a 'capture reaction' involving a stain precursor (e.g., liberated naphthol), we can assume that this reaction should take place as rapidly as possible."

There then follows a remarkably ineffectual discussion of diffusion artefact, which is not given any objective analysis. An example of his critical histochemistry occurs on p. 150. "The sites of enzyme activity in a tissue section when visualized by means of good histochemical techniques should be sharp and clear cut. All available evidence at our present state of knowledge indicates that sharp histochemical localizations are significant even when there is overall cytoplasmic activity (Figs. 5, 6). *Histochemists trained as histologists or pathologists should always expect to see clear cut microscopic localizations provided that proper techniques have been employed*." Regrettably this is typical. One is left to wonder what histochemists who have not been trained as histologists or pathologists may expect to see. One may also wonder how "sharp and clear cut" localization can be induced for weak enzymes of the type that are normally found in the microsomal or supernatant fractions of the biochemists.

Paradoxically, however, it deserves to be reported that it is indeed where he uses totally irrational methods, as for acid phosphatase, that he does get some "background staining"; it is amusing that it should be in this particular case that he considers diffuse staining is permissible.

The contents of the book cover all aspects of enzyme histochemistry. The opening chapter is concerned with fixation and embedding techniques but cannot be recommended. Naphthalene derivatives are then considered briefly as histochemical reagents. The third chapter is useful in that it deals with diazonium salts and azo-dye coupling, which subjects are taken up more fully in relation to tissue sections in the fourth chapter. There then follow chapters devoted to phosphatases, esterases, sulphatases, glycosidases, transglycosylases (which forms a valuable review of these enzymes), proteolytic enzymes, oxidases and dehydrogenases. The additional chapter devoted to the application of enzyme histochemistry to electron microscopy will be welcomed by many, the purpose of the chapter on electrophoretic procedures is less obvious, while that relating carcinostatic agents to histochemical substrates makes little impact. There are a number of printing errors and the photographs often are inconclusive. Apart from the organic synthetic chemistry and the section on aminopeptidase it is not apparent in which way this book appreciably advances the subject technically or theoretically, beyond what has been achieved by Pearse's justly famous work. Moreover, it is very difficult to comment on a work on histochemistry which figures stained muscle bands as mitochondria (Fig. 1, p. 488).

J. CHAYEN

THE MARCH OF SCIENCE

Science in Progress

Thirteenth Series. (SIGMA XI–RESA National Lectureships, 1961.) Edited by Wallace R. Brode. Pp. xiii+305. (New Haven and London: Yale University Press, 1963.) 56*s*.; 7.50 dollars.

To review at all adequately a book which consists of ten lectures on unrelated themes and of the excellence of those contained in this volume is rarely possible within reasonable space. At best all that can be done is to indicate the scope of the volume and the high standing of the lectures. Seven of those contained in this volume are specialized and comprise those of Prof. E. R. Biel, on microclimate, bioclimate and comparative dynamic climatology, Prof. N. F. Ramsey, on nuclear interactions in molecules, Prof. S. Chapman, on Sun storms and the Earth: the Aurora Polaris and the space round the Earth, Prof. T. Dobzhansky, on man and natural selection, Prof. L. M. Beidler, on biophysical approaches to taste, Prof. J. L. Greenstein, on stellar evolution and the origin of the chemical elements, and Prof. S. C. Brown, on plasma physics. Together they provide a fascinating picture of some of the frontiers of science which should be readily intelligible to the non-specialist, and, although delivered in 1960–61 they are none the less to be commended to the general reader.

Three of the lectures have, however, a common theme. From different angles they consider the problems with which the present advance of science confronts society. In the first of them Dr. A. T. Waterman, forecasting the shape of science in the sixties, emphasizes the vital importance of fundamental research, including research in the social sciences, over the whole spectrum of knowledge, and urges that while our organization must be such as to ensure such a distribution of effort it is unlikely to be secured in the absence of effective international co-operation.

Next, Prof. H. Brown examines some of the problems which arise in the relations of science and Government, and he too urges the imperative necessity for international co-operation, stressing first, however, that an effective system of disarmament is an urgent priority, transcending in importance all other aspects of relations between Government and science. Secondly, he directs attention to the contribution of science towards meeting the needs of the under-developed countries and then to the importance of attention to the conservation of natural resources. He concludes that the agencies already established in the United States for providing scientific advice to the Government and concerting national effort and policy in science and technology should be adequate if sufficient attention is directed to these aspects of the situation.

In the third lecture, Dr W R Brode discusses the growth of science and a national science programme, considering what is implied in such a programme and the effect of the growth of science on supporting and performing institutions He suggests that there is a limiting factor to the growth of science and that this is likely to set a limit to the proportion of scientists and engineers, in the United States, he believes this limit is already approached In contrast to Prof Brown, he suggests that national and Government organization of science and science policies in the United States calls for independent review, but he agrees as to the importance of international co-operation, particularly in respect of technical assistance to the underdeveloped countries

These three lectures are thus of general interest, not so much from the information point of view, like the other seven, as from that of a stimulating contribution to a discussion which ranges far outside the United States and is particularly lively in Britain at the moment

R BRIGHTMAN

WHAT GOES UP . . .

Throw Out Two Hands

By Anthony Smith Pp 272+32 plates. (London George Allen and Unwin, Ltd , 1963) 30*s* net

A BALLOON has seemed an uncomfortable thing to me ever since, when I was very young, one came low over a field on my father's farm, a rope was thrown to the men hoeing turnips, but they "weren't touching them things—'tweren't nat'ral", and the balloon deposited its bruised passengers on a gorsy common some miles away Most of East Africa would be much less comfortable for landing than an English turnip field or common, one man told me that the most worrying minutes of his life were in a small aeroplane, the engine of which failed over a sisal estate in Tanganyika, gliding over miles of large erect needle-pointed leaves before they reached the grass beyond

So I admire anyone who has courage to learn ballooning for a few flights over tracts of country where mountains and escarpments rise for thousands of feet, where an equatorial Sun produces violent thermal currents and where forests, lakes and thorn trees make balloon landings very dangerous That was done by Anthony Smith science correspondent to the *Daily Telegraph,* and it is well described in this book

The accumulation of backers, of equipment and funds, the training flights in England and Holland and the arrival in Africa—all that takes up one-third of the book When the prime object was to photograph game in and around the Serengeti Park, I cannot understand why a start was made from Zanzibar, for a short flight to the mainland, in order to face hundreds of miles of bad Tanganyika roads to the game reserves Moreover, it is surprising that, when there was so much expensive equipment, there were no spare ropes so that it should not have been necessary to buy in the Zanzibar bazaar those old cotton ropes which nearly wrecked the balloon at the start

However, Zanzibar seems to have enjoyed the start, and it gave the expedition some adventure before more adventures on the muddy roads of Tanganyika People who visit Africa for adventure usually find it; we who worked there used to look for as much comfort as possible on our limited means, in all my camping I never had the excitement of having my tent flooded by a single storm, with bread, cameras and books floating about

But we were not balloonists and we had not the writer's gift for describing the sensations of ascent, of silent travel and perilous descent, so well portrayed by Mr Smith. Everyone is shocked by their first hearing of the tree hyrax's poignant call, but few could describe it so well. Few could have had the aid of such skilled photographers with such fine equipment, there are some beautiful photographs in colour, for the animals, the clouds and the orange and silver balloon were all photogenic

As I am a botanist, I would have liked to see more of the patterns of vegetation below the balloon and less of the passengers Moreover, I would like to have read more non-ballooning matter, for there are very interesting references to the bogus films of African game, to the cruelty of predators, to the problems of game conservation and counting of animals More emphasis might have been made concerning the great help given to Mr Smith and his party by many people It was surprising that, when Mr Smith had a chance to help a party stuck in the Ngorogoro Crater mud, he delayed that party by leading them into more soft ground, this exploit may have seemed funny to Mr Smith and his companions, but it cannot have seemed funny to the worried African driver, to his belated passengers or to the people who were waiting for them It does not seem funny to me, for I have spent a night in a car stuck in Serengeti mud I am glad that Mr Smith afterwards felt "slightly humble"

The book gives definite results of a trial of ballooning in tropical Africa "Any puff of wind was to be dreaded", there are many puffs of wind in Africa "I do not think balloon photography, to sum up, is very easy, but it is most interesting " So is the book, and, even if the project did little to advance the study of game in Africa (for most of the best photographs were taken on the ground), it may well lead to a revival of ballooning in Britain

A S THOMAS

A SOLUTION FOR MAGNETIC CIRCUIT PROBLEMS

The Nomographic Computation of Complicated and Highly Saturated Magnetic Circuits

By Prof Otto Benedikt Translated by G P Dienes Pp xviii+275 (London and New York Pergamon Press, 1962) 105*s* net

SINCE the earliest days of electrical machine design, one of the frequently recurring problems has been that involving iron under saturated magnetic conditions. Methods have been devised to solve such problems, but invariably the techniques use gross approximations and/or assume linear magnetic conditions which do not exist Generally, in machine design empirical relationships are used, demanding a great deal of experience on the part of the designer in order to obtain reasonably accurate results, while, in more theoretical problems, the custom is to assume linear magnetic conditions in order to render the problem more tractable In the latter case it is usual to add that the conditions are not linear, but that it is necessary to start somewhere, and that a knowledge of the idealized problem will assist in the understanding of the non-linear case Altogether, the subject, up to recent times, has proved to be an unfruitful one for those who would like accurate solutions Of recent years, the importance of finding solutions to these problems has been making itself more and more apparent, and at the present time much effort is being produced to place the subject on a higher level of understanding

The Nomographic Computation of Complicated and Highly Saturated Magnetic Circuits, by Otto Benedikt, would appear to be the result of close co-operation between industry and university It has already been published in Hungarian and German, besides the original Russian, and it is a pity that it was not translated and published in Britain sooner

The author states that the nomographic method, which he sets out in great detail, has been developed over a long period of time He also claims that, whenever it has been possible to check by experiment, the agreement between his theoretical and the experimental results has been good The purposes of the book are to show that the nomographic method is suitable for solving a large number of problems arising in the design and construction of electrical machines and also that the method may be used with some profit to solve other allied problems, some of these he lists in the final chapter

The first chapter deals with the shortcomings of the methods generally used in solving magnetic circuit problems, followed by chapters showing how the nomographic method may be applied to ferromagnetic bodies of varying cross-section and series connected bodies

Chapter 4 considers the much-debated problem of the magnetic relations in the region of the tooth and the magnetically parallel slot This leads naturally to the problems in the next chapters involving the series connexion of a tooth and a magnetically parallel slot, the magnetic relations in the region of tooth, slot and air-gap, the problem of saturated pole-shoes and the estimation of the transverse slot fluxes due to saturated teeth

In Chapter 9, it is claimed that the 'exact' eddy current and hysteresis losses in rotating electrical machines may be calculated by the nomographic method The word 'exact' is perhaps the choice of the translator rather than the author, for it is difficult to see either how the losses could be exactly calculated, or how they could be exactly measured in order to check the calculations However, methods are developed for calculating the various losses in the different parts of the magnetic circuit and also in the copper conductors

Throughout, the mathematics is set out in great detail, with many worked examples to aid understanding, and to illustrate the use of the three sheets of nomograms which are included at the back of the book

The units used are those of the c g s e m u system, which might provide some initial difficulty to those used to the m k s or mixed industrial unit systems It is pleasing to note that Carter's coefficient is mentioned, so presumably Britain is credited in the U S S R with some original work The book was printed in Hungary—this is reflected in the standard of printing which is not quite so good as one generally expects in a modern text-book No bibliography is provided This is unfortunate, since it would be interesting to see what other publications had appeared in connexion with this subject

To those engaged in any branch of non-linear magnetic circuit work, including machine designers, this book should prove to be a useful introduction to the nomographic method Many will find their problems already solved for them and set out in great detail One looks forward to more publications in this particular field

QUANTUM MECHANICS

Quantum Mechanics for Mathematicians and Physicists

By Prof Ernest Ikenberry Pp xii+269 (London and New York Oxford University Press, 1962) 64s net

Mathematics for Quantum Mechanics

An Introductory Survey of Operators, Eigenvalues, and Linear Vector Spaces By Dr John David Jackson Pp x+97 (New York W A Benjamin, Inc , 1962) 3 50 dollars, paper , 4 75 dollars, cloth

According to his preface, Prof Ikenberry's intention is to provide a text on quantum mechanics for graduate mathematicians with little or no background in physics and for physicists with a minimum of mathematics Although the former may feel forsaken by the detailed physical content of the first three chapters on the dual nature of light, the dual nature of matter and the pictorial description of the atom they will find themselves well catered for in the remainder of the book The physicist, on the other hand, will visit the rough in the chapters on wave equations and wave packets, observables and linear operators and quantum mechanical operators but, with diligence, at the end will find his mathematical knowledge no longer minimal

After the introduction of the Schrodinger wave equation in Chapter 8, this book deals with most of the topics which are usually included in books of this kind, the harmonic oscillator, the hydrogen atom and spin, and ends with a very good introduction to relativistic quantum mechanics I myself found the chapters on sectionally constant potentials and eigenfunctions and eigenvalues quite excellent in presentation, scope and completeness Criticism can, however, be directed at the chapter on time independent perturbation theory which is ludicrously short, only six pages, and completely ignores some simple applications of this technique which are of considerable physical interest Indeed, in general, the attention of the reader is not sufficiently directed to the physical interest of the topics considered Comparable books on quantum mechanics contain sections on the quantum mechanics of simple many-particle systems, on applications of variational principles and on simple collision theory These are omitted here

Despite these defects, this book will provide teachers of quantum mechanics with a valuable manual There are 352 problems listed to form an integral part of the text, and abundant references are provided to guide the student in supplementary reading There seem to be few errors or misprints, and the presentation and notation are clear and precise One can hope, however, that the use of the symbol ' Lap" for the Laplacian will not become popular

Dr Jackson's monograph is a mathematical supplement to the course in quantum mechanics for first-year graduates which he gives at the University of Illinois He can justifiably claim to have presented concisely the mathematical methods of quantum mechanics in a form which emphasizes the unity of the different techniques Although Prof Ikenberry's and Prof Jackson's books are being jointly reviewed they are scarcely companion pieces, and it is clear that the courses in quantum mechanics given at Auburn and Illinois are considerably different in emphasis This is not a criticism of either course but is to make the point that maximum value from Prof Jackson's mathematical supplement will only be derived when read along with a companion volume which covers physical topics requiring this kind of mathematical development Such treatises usually provide their own mathematical supplement, either in the text or in appendix form, as in the case of Prof Ikenberry's book Accordingly it is difficult to believe that this book will command a wide sale among students, most of whom will prefer a single comprehensive treatment of the physics and mathematics of quantum mechanics

Considered, however, on its own as an applied mathematical text-book with chapters on eigenvalue problems in classical physics, orthogonal functions and expansions, Stum-Liouville theory and linear operators and linear vector spaces, it is very good Prof Jackson has a way of illustrating and developing mathematical concepts which I found refreshingly novel The reader will take particular pleasure in the use of the Schmidt process of orthogonalization to construct the important polynomial functions of mathematical physics Problems are interspersed throughout the text, and appendixes on the properties of the special functions are provided Teachers and students will find the tables of roots of the Bessel functions especially useful, and at last somoone has thoughtfully provided a key to the choices of spherical harmonic phase factor used in various standard texts on quantum mechanics This key could be more comprehensive, but it seems clear that in this connexion Prof Ikenberry prefers to be with the minority

A L Stewart

The Evolution of Living Organisms

Edited by Prof G W Leeper (A Symposium to mark the Centenary of Darwin's "Origin of Species" and of the Royal Society of Victoria, held in Melbourne, December, 1959) Pp v+459 (Melbourne The University Press London Cambridge University Press, 1962) 126*s* net

THIS interesting volume includes thirty-six contributions from workers distinguished in a wide variety of fields including evolution, genetics, and population dynamics The volume is divided into two parts of approximately equal length In the first part, twenty papers are collected under the heading, "Evolution and Selection" Although the scope and content of these papers differ very widely they are impressive contributions in their respective fields The first paper, "Accident or Design, the Paradox of Evolution", by E Mayr, is a brief but important, summary of the history of ideas on the origin of adaptation As Mayr points out, evolutionists are now closer in their thinking and in their entire interpretation of evolutionary events to the Darwin of 1859 than they have been at any time in the past hundred years Some of the other papers deal with very restricted aspects of the subject, for example, chromosome breakage in *Astroloma* and effect of chromosome inversions on size and viability of grasshoppers, while others, such as those on the origin of life, the evolution of dominance, and the survival of the mediocre, are clearly of more general interest

The 16 papers included in the second part of the volume are concerned with the distribution and evolution of the Australasian fauna and flora, and provide a wealth of detailed information indispensable to anyone with an interest in the fauna and flora of this area

In considering the origin and distribution of the animals and plants of the southern continents, one's attitude to the theory of continental drift becomes crucial in a sense that it scarcely ever does when dealing with groups restricted to the northern hemisphere, where the movements of the continents relative to one another have been much less Acceptance or non-acceptance of the theory of continental drift not only affects at various levels the manner in which factual evidence of past and present distributions is interpreted, but it also seriously affects conceptions about the phylogeny of many groups For these reasons it seems a pity that more attention has not been directed to this basic problem, although the few authors who have touched on it seem to reject the possibility of continental drift H E HINTON

Symbiotic Associations

Thirteenth Symposium of the Society for General Microbiology held at the Royal Institution, London, April 1963 Edited by P S Nutman and Barbara Mosse Pp x+356 (London Cambridge University Press, 1963) 50*s* , 9 50 dollars

THE Society for General Microbiology has a well-deserved reputation for its symposia They are planned to cover a wide field and to point toward future developments, and not simply to summarize existing knowledge on a narrow topic This, on symbiosis in micro-organisms, is another worthy successor in the series It shows both the strength and weakness of this approach The topics range from bacteriophages to lichens Every microbiologist will surely find fascinating new facts on material which is unfamiliar to him This wide appeal is the result of the wide range The weaknesses are also apparent Few of the articles are detailed and up-to-the-minute reviews of the kind that are so much in demand nowadays This is expected as a necessary consequence of the general policy of these symposia However, more serious defects are seen in a few of the contributions In some the subject-matter has not been related carefully to the problem of symbiosis This is particularly marked in the section on bacteriophages In others the theory of symbiosis is skimmed over The standard of writing is nevertheless commendable, and nearly all the articles are easy to follow

The chapters fall into three sections First, there is an introduction by R Dubos and A Kessler This, on general factors of symbiosis, is stimulating but not very clearly written The second section is entitled "Plant Associations" It includes sections on lichens (surely among the most remarkable forms of life), on legume nodules, and on mycorrhiza The third section is on animal associations, many of which are fascinating, for example the symbionts of insects, discussed by Marion A Brooks, and the chapter on algae and invertebrates by M R Droop J M Baker contributes a fine chapter on the ambrosia beetles and their fungi Two articles deal with associations in the rumen The book is well produced, and errors are commendably few P H A SNEATH

Quantum Statistical Mechanics

Green's Function Methods in Equilibrium and Non-equilibrium Problems By Dr Leo P Kadanoff and Dr Gordon Baym (Frontiers of Physics a Lecture Note and Reprint Series) Pp xi+203 (New York W A Benjamin, Inc , 1962) 4 95 dollars, paper, 6 95 dollars, cloth

THE principal problem of quantum statistical mechanics is the many-body problem It consists essentially of finding methods for evaluating equilibrium and non-equilibrium characteristics of large assemblies of particles Recently new methods for investigating this problem have been developed which are based on the mathematical techniques of quantum field theory One of the most effective of these techniques is the quantum mechanical Green's function method developed by Martin and Schwinger This book consists of a set of lectures on this Green's function method by two of their former students

In all, there are thirteen chapters The first five are devoted to the original work of Martin and Schwinger on the equilibrium Green's function and to methods for deriving approximations to the Green's function The following six chapters outline a theory of non-equilibrium phenomena, including a generalization of Boltzmann's equation with applications to sound propagation and the Landau theory of Fermi liquids These six chapters owe much to the original research of the authors The last two chapters discuss the use of the shielded potential to describe a Coulomb gas and the application of the two-body scattering matrix approximation to systems with short-range interactions

Being essentially a collection of lecture notes the style is informal and at times brief, with an emphasis put on a mathematical analysis of the problems discussed There is no index and, except for a list of supplementary reading matter at the end, there are few references The lectures are suitable only for the serious student of statistical mechanics who is familiar with quantum mechanics and with second quantization Such a student should find this a useful addition to his library The book would be of little use to the student who wishes only to apply statistical mechanical results to specific problems F J SMITH

Abstract Harmonic Analysis

By Prof Edwin Hewitt and Prof Kenneth A Ross Vol 1 Structure of Topological Groups—Integration Theory—Group Representations (Die Grundlehren der Mathematischen Wissenschaften, Band 115) Pp viii+519 (Berlin Springer-Verlag, 1963) 76 D M

IN the theory of Fourier series one deals with periodic functions, which may be considered as functions defined on a circle, with the circular functions *sine* and *cosine* taking a special role The subject of this book, abstract harmonic analysis, can be regarded as a vast generalization of the theory of Fourier series in which the circle is replaced by any topological group, which is either compact or locally compact and Abelian (The case of a non-Abelian group, which is only locally compact, has a less complete theory and is outside the scope of the present work) In the generalized theory, the role of the circular functions is played by the matrix elements of the irreducible matrix representations of the group It is remarkable how many of the theorems about Fourier series survive such a broad generalization

The development of the theory requires a great deal of special knowledge about topological groups, integration theory and invariant measures on groups Even though the authors do not hesitate to refer to standard texts whenever possible, their treatment of this preparatory material occupies the first half of the volume, and constitutes a valuable addition to the text-books of these subjects Only in the last two chapters, on convolutions and group representations and on characters and duality of locally compact Abelian groups, does the harmonic analysis proper begin Full details of the subject are reserved for the second volume There are appendixes on Abelian groups, topological linear spaces and normed algebras, and a good bibliography

Text-books at this advanced level not uncommonly make very heavy reading, and so it is a pleasure to report that the authors have obviously made great efforts to ease the way for those readers who are not already experts Thus the proofs are written out in very good detail An abbreviated first route through the book is recommended Nearly all the twenty-six sections contain a large collection of examples and miscellaneous theorems to round out the general theory There are also notes commenting on the history of the leading ideas of the section, and giving references to alternative treatments and further developments Thanks are due to the authors for producing a book which will serve well both students and experts in its subject T A S JACKSON

Textbook of Organic Chemistry

By Prof Alexander Gero Pp ix+679 (New York and London John Wiley and Sons, Inc , 1963) 72*s*

PROF. GERO has had long experience of industrial research and university teaching, and the latter is the basis of this book Although it starts with an introductory survey of organic chemistry and of electronic theory it is a university book rather than one for schools.

A preliminary fifty-page chapter deals with relatively simple compounds and their reactions A second one deals with fundamental theories, explaining the nature of organic reactions on the valence-bond theory rather than on molecular-orbital theory which Prof Gero finds less suitable for many of his students owing to their inadequate background of physics and mathematics The latter theory is included in a penultimate chapter A final chapter is on physical methods used in organic chemistry It discusses concisely the use of the polarimeter and *p*H-meters, of ultra-violet and infra-red spectroscopy, molecular resonance and various resonance spectra

Separation of aliphatic from aromatic compounds is abandoned after the preliminary chapter, and related types, for example, alcohols and phenols, are considered together Physical properties receive full consideration, but the aim is not a load of facts but a balance of them with theory so that the student shall "understand how and why reactions take place" Practical instructions are not part of the book The main part of the book comprises twenty-three chapters on groups of compounds selected for their importance in giving a worth-while picture of the subject, two on stereochemistry and one each on the hydrocarbon-based industries and the plastics industry and polymerization There are two chapters on polyfunctional compounds, three on heterocycles and one each on isoprenoids and steroids Many chapters conclude with a useful summary and almost all of them with a selection of questions

The book is produced to the high standards that are to be expected from American text-books H DUNNICLIFF

Birds of Hampshire and the Isle of Wight

By Edwin Cohen Pp xii+278+16 plates (Edinburgh and London Oliver and Boyd, Ltd , 1963) 30*s* net

ONE of the signs that birds are the most popular group of animals among British naturalists is the existence, for every county in England and most of those in Wales, of a book or at least a booklet devoted entirely to their birds But so great has been the increase in our knowledge of the migration and breeding distribution of British birds resulting from the remarkable upsurge of amateur observation in the past thirty years, that any county avi-fauna not published within that period (or indeed within the past ten years) is likely to be seriously out of date This was certainly the case with Hampshire and the Isle of Wight, where the standard work dated from 1905, and this new book by Edwin Cohen, who has for so long been associated with the county's ornithology, will therefore be most welcome to bird watchers both in and out of Hampshire

Much of the value of such a work depends on the thoroughness with which the author has both combed the vast and scattered literature and vetted the records of rarities, in these respects Mr Cohen has been exemplary Though the main part of the book consists in the usual annotated systematic list of the individual bird species, there are also some useful introductory chapters D W Wray writes on geology, Mrs A K Hunt on botany, and six authors deal with birds in relation to habitat and land use in the county divided into seven regions J S Ash on the Fordingbridge area, D F Billett on the south-east corner, E L Jones on north-west Hampshire, J Stafford on the Isle of Wight, J H Taverner on the Winchester area and part of the Solent shore, and the author himself on his home region, the New Forest R S R FITTER

A Study of Reptiles and Amphibians including their Care as Pets

By Alfred Leutscher Pp 80 (London Blandford Press, Ltd , 1963) 10*s* 6*d*

ALFRED LEUTSCHER has written yet another popular account of reptiles and amphibians intended for the lay reader Three-quarters of the text is a thumbnail sketch of the origin, evolution, classification, biology and habits of the reptiles and amphibians, with a short chapter on popular misconceptions The remaining quarter concerns the care of these creatures in captivity and simple experiments and observations that nature groups and others might carry out For the person to whom herpetology is a new interest a fair background to the subject is given, but some wildly inaccurate facts and figures are also presented and an outdated classification of the amphibia used, which suggest that the author is unfamiliar with the literature and with many of the animals

A few examples will suffice In describing caecilians, the author states that "*behind* each eye is a small tentacle on the face" The leathery turtle is defined as having "a soft leathery skin with only *a few* bones in it", there are in fact many hundreds The pineal eye of the tuatara is reported as possessing an *iris* (My italics) But the most astonishing definition is that given to the Reptilia "they are distinguished from all other vertebrate animals in having lungs and limbs, and their bodies covered in a protection of scales". Into this category the uninitiated might gleefully place the armadillo, pangolin and the lung fishes While the photographs are good, the line drawings are of limited use and some are even grossly inaccurate If a competent illustrator was not available, reproduction of early figures of snake skulls would have been infinitely more reliable than the author's diagrams, which feature a puzzling arrangement of bones with an apparently fractured pterygoid hinged to the lower jaw

A G C GRANDISON

THE ROYAL SOCIETY

ANNIVERSARY ADDRESS*

By Sir HOWARD FLOREY, P.R.S.

AWARD OF MEDALS, 1963

Copley Medal: Sir Paul Fildes, F.R.S.

SIR PAUL FILDES has the enviable distinction of being the pioneer chiefly responsible for opening up a vast new field of microbiological research. His early studies, more than half a century ago, on the growth factors of *Haemophilus influenzae* and related organisms and his elucidation of conditions requisite for the sporulation and germination of anaerobic bacteria of the tetanus group, both *in vitro* and in the infected animal, were notable achievements in their own right. Their chief importance, however, lay in the fact that they convinced Fildes that the key to the rational control of microbial infections lay in a full knowledge of the nutritional requirements of the causative organisms and elucidation of the biosynthetic precursors involved in the utilization of essential nutrients. He was probably the first to recognize the necessity of close collaboration between bacteriologists and biochemists for fruitful investigations along this line of approach. To this end he established in 1934, under the auspices of the Medical Research Council, a team which, under his leadership, pioneered the way into the field of bacterial chemistry.

Of the many notable discoveries resulting from the work of his unit perhaps the most outstanding was the demonstration of the inhibitory action of the sulphonamide drugs on the utilization of *p*-amino-benzoic acid in bacterial synthesis. This discovery provided the stimulus for the intensive search for analogues of essential growth factors for use as chemotherapeutic agents, a search which is still being carried out on a world-wide scale.

The influence which Fildes's work has had on biological research extends far beyond the realm of medical microbiology. Stemming from his discoveries came the realization that bacteria provide the best material for the investigation of many of the fundamental, and interlinked, enzymatic processes on which the life of higher organisms, including man himself, depends. Equally the development of bacterial genetics would have been impossible without the background of knowledge derived from the exploitation of his early concepts.

Fildes still continues in active research, and during recent years has published important papers on interactions between bacterial viruses and bacterial host cells.

A Royal Medal. Prof H. H. Read, F.R.S.

Prof Read has achieved an international reputation for the contributions he has made to the understanding of metamorphism and the interpretation of granites. Trained in the hard practical school of the Geological Survey before he entered academic life, he has always appreciated that theories of space and time in geology must stand up to the observed facts of field work. It is for this reason that his work on low-load metamorphism, metamorphic differentiation and polymetamorphism has placed him in the acknowledged position of a leader with a large and successful school of workers following the directions in which he has pointed.

His work on migmatites led him to look at the problems posed by the existence of granites and to develop the concept of the Granite Series. In his famous book *The Granite Controversy*, he fitted granites according to their composition, form and environment into the framework of mountain, fold or mobile belts. From an international point of view, it is for this work that he is probably best known, but we should not forget the many pieces of carefully detailed field interpretations of Scottish metamorphic and igneous rocks, nor, on a different plane, his ability to write excellent text-books.

A Royal Medal: Dr Robert Hill, F.R.S.

Dr Robert Hill is distinguished for many original contributions to biochemistry but particularly for his outstanding work on the processes involved in photosynthesis. His first research on the affinity of different hæmoglobins for oxygen led to the development of a sensitive quantitative test for measuring oxygen produced in reaction systems, and by applying this test to isolated chloroplasts he discovered the now famous Hill reaction. He demonstrated that isolated chloroplasts have oxido-reductive systems activated by light, that oxygen production is independent of carbon dioxide fixation but requires an electron acceptor, which need not be specific because naturally occurring compounds could be replaced by such substances as ferric oxalate. His identification of the light-induced reaction with the photolysis of water initiated current investigations in cell-free systems of the photochemical phase of photosynthesis, and his lucid formulations of the problems contain most of the concepts on which work fruitfully proceeds. Hill recognized an enzyme involved in the oxygen-yielding system, and this was later purified and crystallized. He also identified cytochromes peculiar to chloroplasts, and it is generally accepted that these are concerned in an electron transport system connected with photosynthesis. Although Hill is best known for his work on photosynthesis, he has also contributed much to knowledge about the role of cytochromes in respiration, and he was one of the first to investigate isolated mitochondria from plants. His remarkable insight into biochemical processes has kept him consistently as a pioneer, able to design experiments that seem simple because they are made without elaborate equipment but that produce decisive and novel results.

Davy Medal. Dr E J Bowen, F.R.S.

Dr Bowen has made many contributions to physical chemistry, but undoubtedly his main work has been the investigation of phenomena involving the interaction of matter and radiation. He was among the first to examine the mechanism of photochemical processes in terms of quantum theory at a time, forty years ago, when the significance of Einstein's law of photochemical equivalence was not clear. He investigated the photo-decomposition of a number of simple gases such as ozone, the hydrogen halides, and the oxides of chlorine. Some of these reactions show simple behaviour, and Bowen's results, together with those of Warburg provided some of the earliest verifications of Einstein's law. Other reactions, however, showed deviations from the law, and Bowen studied further the decomposition of aldehydes and ketones and the photo-oxidation of hydrocarbons and alcohols. Low quantum yields in liquid-phase reactions were attributed to primary recombination, and high yields to chain reactions.

His attention later turned from photochemistry to the phenomena of luminescence, phosphorescence and fluorescence, and particularly to the quenching of fluorescence. Much of his work was done with anthracene and other polynuclear hydrocarbons such as rubrene, naphthacene, pentacene and coronene. For anthracene he demonstrated elegantly the interrelation between fluorescence, photodimerization and photo-oxidation. The relative efficiencies of different molecules in quenching fluorescence gave information about the variety of interactions involved, ranging from perturbation by van der Waals forces to highly specific transfers of electronic energy. A knowledge of the absolute magnitudes of quenching efficiencies, together with their variation with temperature and viscosity, yields information about collision processes in liquids which is difficult to obtain in any other way.

---

* Delivered at the Royal Society on November 30

Some of Bowen's earliest work was on chemical reactions and fluorescence in solids, and recently he has returned to an investigation of fluorescence in solids and gases. In particular, his work on solid solutions of naphthacene in anthracene shows how a photon absorbed by one component can be transferred over considerable distances in the solid before it excites fluorescence of the other component; this kind of energy transfer is of importance for theories of the solid state. He has always been interested in the application of fluorescence and other optical measurements to other sciences, and has published papers on the use of fluorescence for analysis, the action of light on dyes, photosynthesis, and a method for making visible streamlines in fluid flow.

A marked characteristic of Bowen's experimental work has been the skilful use of simple apparatus.

Hughes Medal: Prof. F. C. Williams, C.B.E., F.R.S.

Prof. Williams's war-time contributions to the development of radar were inevitably somewhat obscured by the circumstances of the time, but it was generally understood that they were of considerable importance. They were recognized by the award of an O.B.E. in 1945, and he received the premier premium award of the Institution of Electrical Engineers, the 'Institution Premium', for a group of papers on pulse techniques and associated circuitry which he presented to the I.E.E. Radar Convention held in 1945.

On returning to the University of Manchester in 1946, his primary interest became the development of digital computing machines, in collaboration with T. Kilburn, and he soon perfected a cathode-ray-tube storage system which formed the central part of the Manchester computor which began to operate in 1948. This was the prototype of the first Ferranti *Manchester Mark I* machine which was installed in the University in 1951, and this machine was unquestionably the first commercially made saleable machine in the world. In addition to the cathode-ray-tube store, several other novel features were incorporated which are common to most present-day digital computors. Williams was the inspiration behind the early-stage development of digital computors in Great Britain and his work exercised a considerable influence on similar developments in other parts of the world.

Later his interests turned from electronics to electrical machines. His objective is to devise a brushless variable-speed a.c. motor and some progress has been made towards this. It appears that practically any pair of 'even pole number' speeds can be provided by his method using a simple switching system, and that at least five speeds can be obtained at the cost of rather more complex switching arrangements. There seems little doubt that these machines will find rapid acceptance in industry, since the two-speed version shows a saving of one or two frame sizes over the double-wound equivalent.

This work is now being extended to cover multi-frequency alternators by pole-changing methods, and various schemes are under consideration for application to electric and Diesel electric traction. Present experiments are concerned with the application of semi-conductors to rotating machines. In all this machine work, Williams has been ably assisted by many colleagues, but the inspiration has again come from him.

The quality of his work and of his authorship may be judged from the fact that he has been awarded, either individually or in association with his staff colleagues and research students, no less than nine premiums of the Institution of Electrical Engineers, including the Kelvin and the Sylvanus Thompson Premiums each on two occasions.

Leverhulme Medal: Dr. A. J. P. Martin, C.B.E., F.R.S.

Dr. A. J. P. Martin has been the central figure in the development of chromatography, the outstanding advance in the techniques of chemistry for the past quarter of a century.

The most important part of this work was carried out during his service as a chemist at the Wool Industries Research Association in Leeds (1938–46) and later on the staff of the Medical Research Council in London (1948–56). Through this period, and particularly during the past fifteen years, chromatography has emerged in a variety of forms as a method of analysis, separation and purification of the greatest value to chemistry. Dr. Martin's outstanding contributions to this explosive growth have been widely recognized by numerous awards including that of the 1952 Nobel Prize for chemistry (jointly with Dr. R. L. M. Synge), the Berzelius Gold Medal of the Swedish Medical Society (1951) and the Franklin Institute Medal (1959).

The methods of chromatography have become so much a part of chemical practice, and in so short a time, that they scarcely call for description. Like distillation, crystallization and titration, they form part of chemical operations in laboratories throughout the world. In all the main sections, paper chromatography, column or partition chromatography, and the later gas chromatography, Martin played a leading part, and his work led on to later technical modifications and extensions such as ion-exchange and reversed-phase chromatography. His inventiveness, imagination and resourcefulness have been linked with a full understanding of basic principles, and have enabled earlier disconnected observations to be converted into sound general methods of extraordinary and sweeping range. Paper and partition chromatography enabled new fields of organic, biochemical and medical research to be successfully attacked, and later applications to inorganic analysis have been of great benefit. Gas chromatographic procedures, with their auxiliary methods of detection and measurement, have attained a remarkable elegance and have presented the chemical and petroleum industries with a most valuable analytical tool.

The applications of chromatography to-day are fantastically diverse. They range from the investigation of cosmology to that of disease, and from the evaluation of mineral deposits to that of Old Masters.

ACCOMMODATION OF THE ROYAL SOCIETY

This year I have been faced with more than the usual difficulties in deciding what I should say in this anniversary address. I wrote one version in a euphoric frame of mind engendered by perfect weather enjoyed in the shade of banana trees not very many miles from the monument to Captain Cook's landing in Tahiti to observe the transit of Venus. In that respect the address might well have been unique. But a return to the less salubrious climate of Great Britain has forced me to admit that the full course of the negotiations for improved accommodation for the Society has not yet been run. Nevertheless I have some reason to believe that they will be successful, so that with the agreement of the officers I will try to tell Fellows what is happening and where we stand.

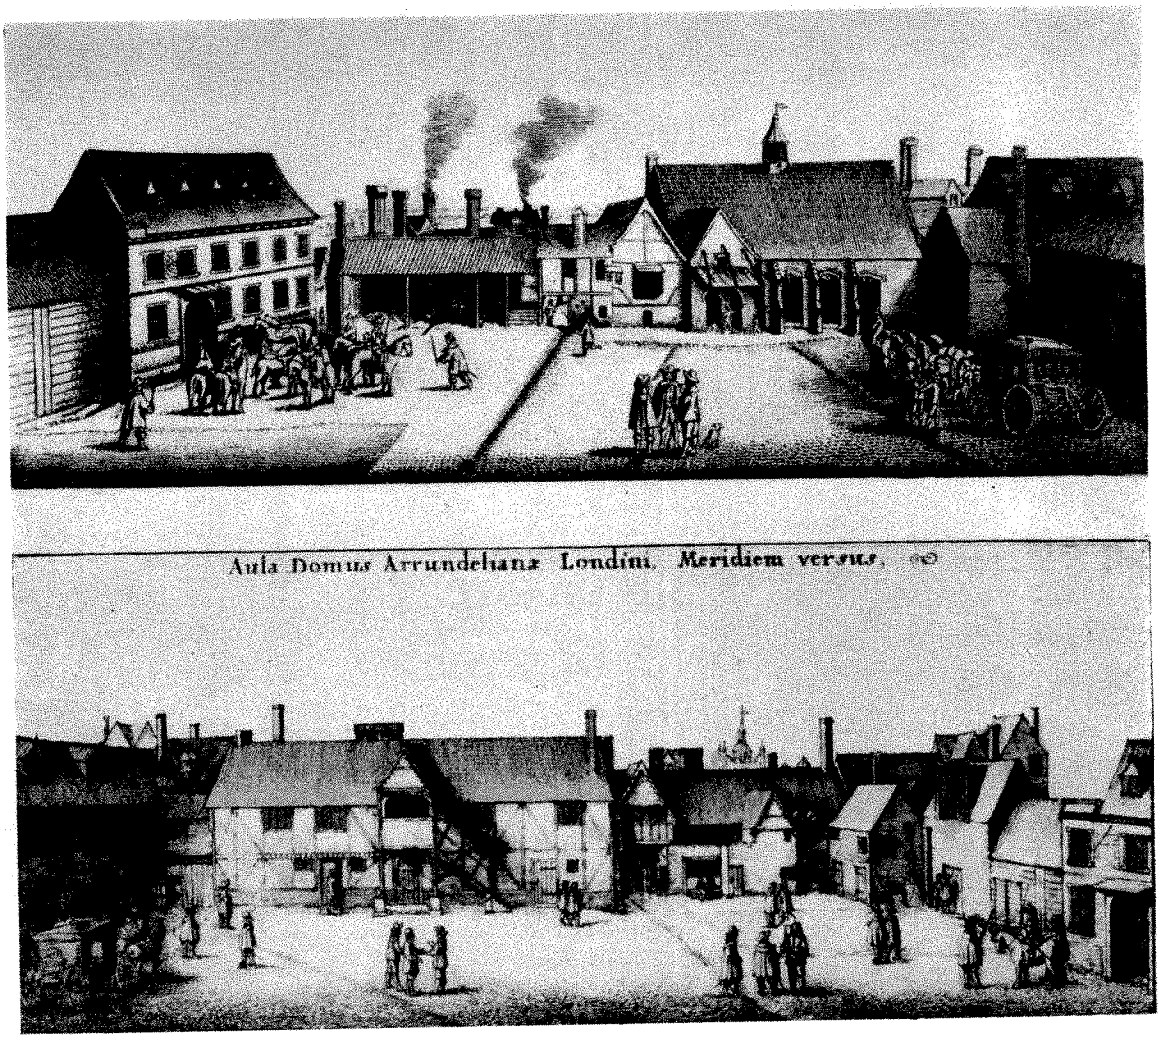
Some of the older Fellows will remember that Sir Henry Dale devoted his presidential address of 1943 to a consideration of the accommodation of the Society, which was not only inadequate for its activities at that time but had been so for many years. He gave a sketch of the previous arrangements for the housing of the Society and drew some conclusions not only about our own post-War needs but also about those of numerous other scientific societies. To give a background to what I have to say about present developments, I propose to repeat some of his remarks in the hope that the older Fellows will not have a clear recollection of what Sir Henry said and in the confident belief that few of the younger Fellows read former anniversary addresses.

The question of a building in which it could function effectively has exercised the Society on and off ever since its beginning. Soon after its foundation the original rooms which had been put at its disposal by Gresham College (Fig. 1) had to be evacuated because the College was needed for the Royal Exchange—the buildings of which had been destroyed in the fire of London in 1666.

Mr. Howard, who was later to be the sixth Duke of Norfolk, then offered the Society rooms in Arundel House (Fig. 2) the site of which is now marked by Arundel Street and Norfolk Street near the Strand. This offer was gratefully accepted by Council, and the first meetings were held in Arundel House in January 1667. These rooms were occupied for six and a half years, during which time Council began to discuss the provision of more permanent accommodation, and, in the modern manner, appointed a Committee which, as is sometimes the case in our own day, accomplished little. It was perhaps not to be unduly blamed for this, for great hopes were raised by the gift of Chelsea Hospital to the Society by Charles II. But the buildings were unfortunately dilapidated and in need of repair, and in spite of strenuous efforts money could not be raised for their restoration. Generous donors were, however, not entirely lacking, for Mr. Howard gave the Society 4,000 sq. ft. of the grounds of Arundel House on which to build. Unfortunately difficulties arose with regard to this site and, what was ultimately more serious for the Society, with regard also to the Chelsea Hospital site. So, in spite of apparently great efforts, nothing came of the negotiations, and to the lasting and serious deprivation of the Society the Chelsea site was handed back to Charles II in 1682 for the payment of £1,300. It was, to be sure, quite reasonable for the President and Council of the day to consider this to be in the best interests of the Society, and no doubt we should have taken the same course to-day if confronted with the same situation.

During this period Hooke made proposals for building what was described as a "handsome fabric for the Society's use, with a library, repository, laboratory and other conveniences for making experiments". But it appears that he never put his plans on paper.

Another effort which came to nothing was to include rooms in a rebuilt Gresham College. Wren was asked to consider what accommodation the Society needed and to produce a suitable design. Unfortunately the proposals, which had the full support of Gresham College, were among a number connected with the College which needed an Act of Parliament for their implementation, and the Act when brought before the House was rejected at the first reading. This made it necessary for Council to take vigorous measures to find premises, their efforts being stimulated when the Mercers' Company let it be known in 1705 that they were not prepared to let the Society have any room at all in Gresham College. Many explorations were made, including a petition to Queen Anne for a grant of land at Westminster; but they came to nothing



Aula Domus Arrundelianæ Londini, Meridiem versus.

Fig. 2. Arundel House

until in 1710 two houses were bought in Crane Court where the Society remained until 1780 (Fig. 3).

The bald statement that the houses were acquired scarcely conveys the effect on some of the Fellows of this decision by the President, Sir Isaac Newton, and Council. There was a stormy meeting about the proposals and a good deal of acrimonious comment was made; but this did not deflect the President and Council in whose competence the decision rested. The President, it seems, behaved with mule-like obstinacy. But within a short time all this was forgotten, and although the accommodation of Crane Court was never adequate the Society flourished there to such an extent that it acquired a reputation as a body of national importance, with the result that in 1778, thanks to the personal interest of George III, the Government agreed to provide rooms rent free and indeed free from any financial obligations at all, an arrangement which has happily continued ever since.

Discussions took place to accommodate the Society in the new Somerset House (Fig. 4), which was to be designed by the architect Sir William Chambers to house a number of bodies, including the Royal Academy. The space offered to the Society seemed to the Council to be inadequate, but after some rearrangement of the rooms had been proposed it was concluded that the conditions were so favourable that the Government's offer should be accepted. The houses in Crane Court were consequently sold; and it is not without interest that they brought in only £1,000, although seventy years before they had cost £1,450. This is a sharp and interesting contrast with the modern trend in property values.

The rooms in Somerset House were never sufficient for the Society's needs, although the meeting room was certainly elegant. By 1852 the congestion had become so acute that the Library Committee recommended that Council should raise with the Government the whole question of the future accommodation of the Society.

About this time the idea took root that it was desirable to bring the major scientific societies under one roof, by which arrangement they could share meeting rooms of various sizes and have co-ordinated library facilities without impairing the independence of the societies. Considerable pressure towards this goal was exerted by a newly formed dining club, the Philosophical Club, which had started to consider the preparation of a memorandum on the subject as early as 1847. It appears that it was through this Club that a proposal was made that the Society should endeavour to obtain Burlington House from the Government in place of the rooms in Somerset House, and in 1856 this was proposed in an official letter. The Government were not then in a position to give a definite undertaking, but agreed that at least temporary premises should be provided in Burlington House for the Royal Society and some others. This offer was accepted (Fig. 5). Burlington House has undergone a number of changes. Originally it must have been a very desirable and commodious town residence. It was altered by the Lord Burlington of the day according to the plans prepared in 1717, after which it probably remained essentially unaltered so far as its exterior was concerned until the middle of the nineteenth century when it appeared as shown in Fig. 6.

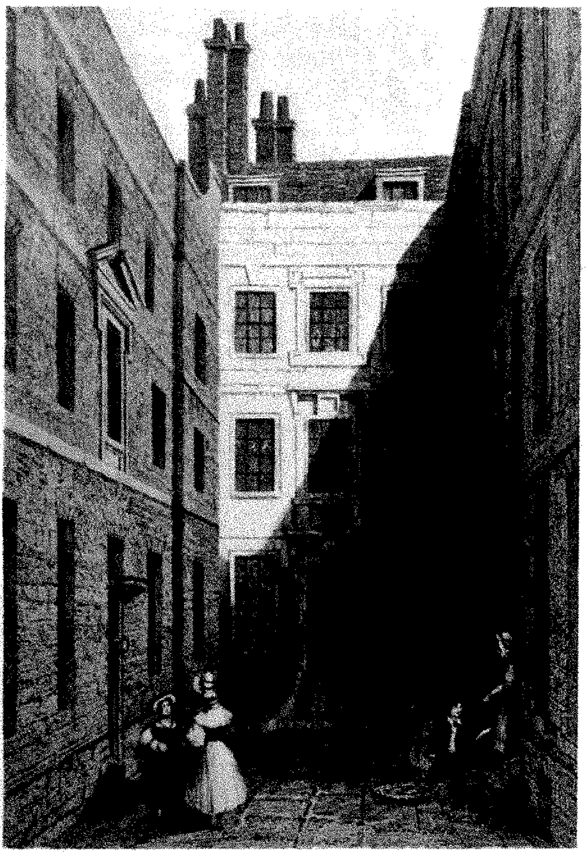


Fig. 3. The Houses of Crane Court

In the interval between the Great Exhibition of 1851 and the acceptance of the Government's offer of Burlington House another suggestion had been made. With the profits of the Exhibition, land had been purchased in Kensington Gore, and it was proposed to group the most important scientific societies there. However, the scheme was rejected by the interested societies, who wanted a more central position, for at that time Kensington Gore was almost in the outer suburbs. The idea of what has recently been called a 'Science Centre' was thus clearly formulated by our predecessors more than a century ago.

The occupancy of Burlington House by the Royal Society, which began in 1857, did not long remain undisturbed, for in 1866 the Government decided to allocate it to the Royal Academy. The manner in which this event was announced seems to indicate that the Royal Society was not esteemed as highly in ruling Government circles as the Fellows might have wished or may indeed have imagined, or that in some way it had been outmanœuvred. The first information that the Society had of the impending move came from the columns of *The Times* of 1867 in the form of a statement that the Government had decided to give the Royal Academy a permanent lease of Burlington House with the right to extend northwards. Sir Edward Sabine, the President, was away at the time—let me hasten to add very properly so, as it was during the summer vacation—but then, as now, the Society had an alert treasurer, Prof. W. A. Miller, who promptly wrote to the Prime Minister, Lord Derby, to enquire if the announcement was true. It was.

The Government wished to use the building the Royal Academy occupied in Trafalgar Square for what is now the National Gallery, and so the Academy had to move. To what better place than Burlington House? The Royal Society then went through five years of considerable

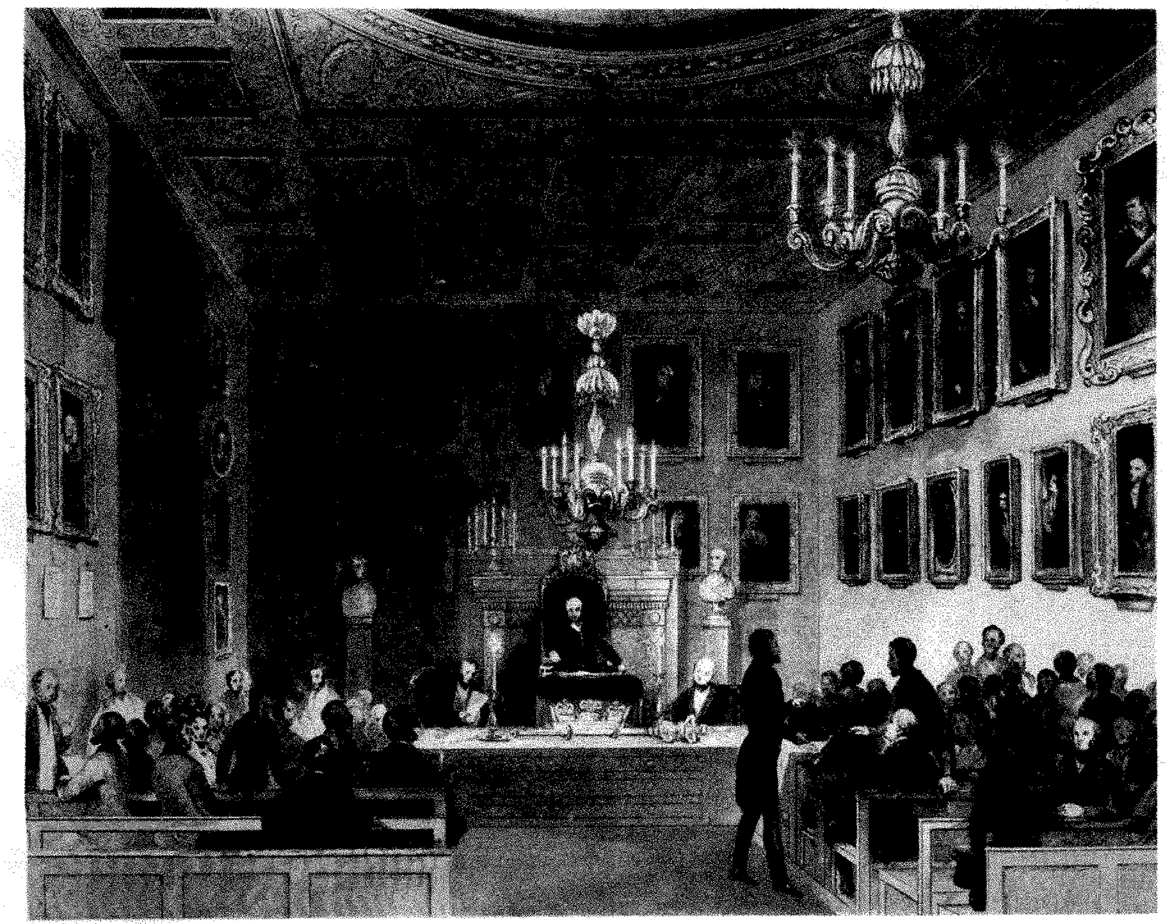

Fig. 4. The Meeting Room in Somerset House

difficulty, and, I have no doubt, discomfort and annoyance while the Burlington House that we know was constructed.

The Royal Society was then allotted its present rooms, the occupation of which was completed by November 30, 1873, when the anniversary meeting was held here.

The utilization of the magnificent site surrounding Burlington House for scientific societies was further complicated by the construction of what is now known as Burlington Gardens on the northern portion of the area. Burlington Gardens was built to accommodate the University of London, and as it was principally to be used for examinations it was constructed with a number of extremely large rooms.

As Sir Henry Dale pointed out, a magnificent opportunity to provide adequately for the growing scientific societies was lost, for the buildings allotted to them around the quadrangle on the Piccadilly side could not be enlarged, and even when first constructed they were not more than sufficient for present-day needs. Nor could the original conception of some integration of the facilities of the societies be carried out.

The Society had not occupied its present rooms for long before pressure on space began to grow once more. This was already evident by 1900 when at a meeting of the Council of the Society held on March 22 "the Senior Secretary reported that, having learnt in an indirect manner that the Government was considering how to make use of the building in Burlington Gardens, about to be vacated by the University of London, he had written privately to Lord Esher explaining that the present rooms occupied by the Society were rapidly becoming inadequate for its proper accommodation and desiring him to consider whether the Society might not with advantage be transferred to the above vacant building". But this was not to be, and the Civil Service Commission was installed in Burlington Gardens (Fig. 7).

The pressure on space has continued to build up. Some indication of the growth of the activities of the Society is given by the fact that there are now over 100 committees—committees, let it be emphasized, which actually do something—and that to serve them and the other functions of the Society the permanent staff has grown from 2 in 1873 to 70 in 1963. Fellows who have inspected the premises in detail in recent years must have been astonished at the cramped and inadequate conditions under which the constantly growing executive staff have been doing their work with such efficiency and success.

In the anniversary address of 1950 Sir Robert Robinson gave a résumé of the negotiations that had been going on since 1944 for the improvement of the accommodation of scientific societies. These negotiations culminated in proposals to establish a 'Science Centre' which was to house a number of societies including the Royal, as well as Government scientific organizations such as the Department of Scientific and Industrial Research. This centre was to act as a focus for both national and international scientific activities. The site chosen for the centre was on the South Bank, and the Government offered to finance the project. The President said: "All the fundamental aspects have been agreed in principle and, if we are now to be disappointed, it can only be as the result of some grievous calamity". The fact is that the offer of the Government was withdrawn in 1958. What the judgement of posterity will be it is impossible to say, but I sometimes have a fleeting thought when looking at the splendid panorama of the Thames from the Festival Hall that our successors may want to know why this scheme did not come to fruition, and no doubt this will furnish an interesting article for *Notes and Records* in, say, fifty years' time.

The problems of accommodation continued to press, and so about three years ago I enquired from the Execu-

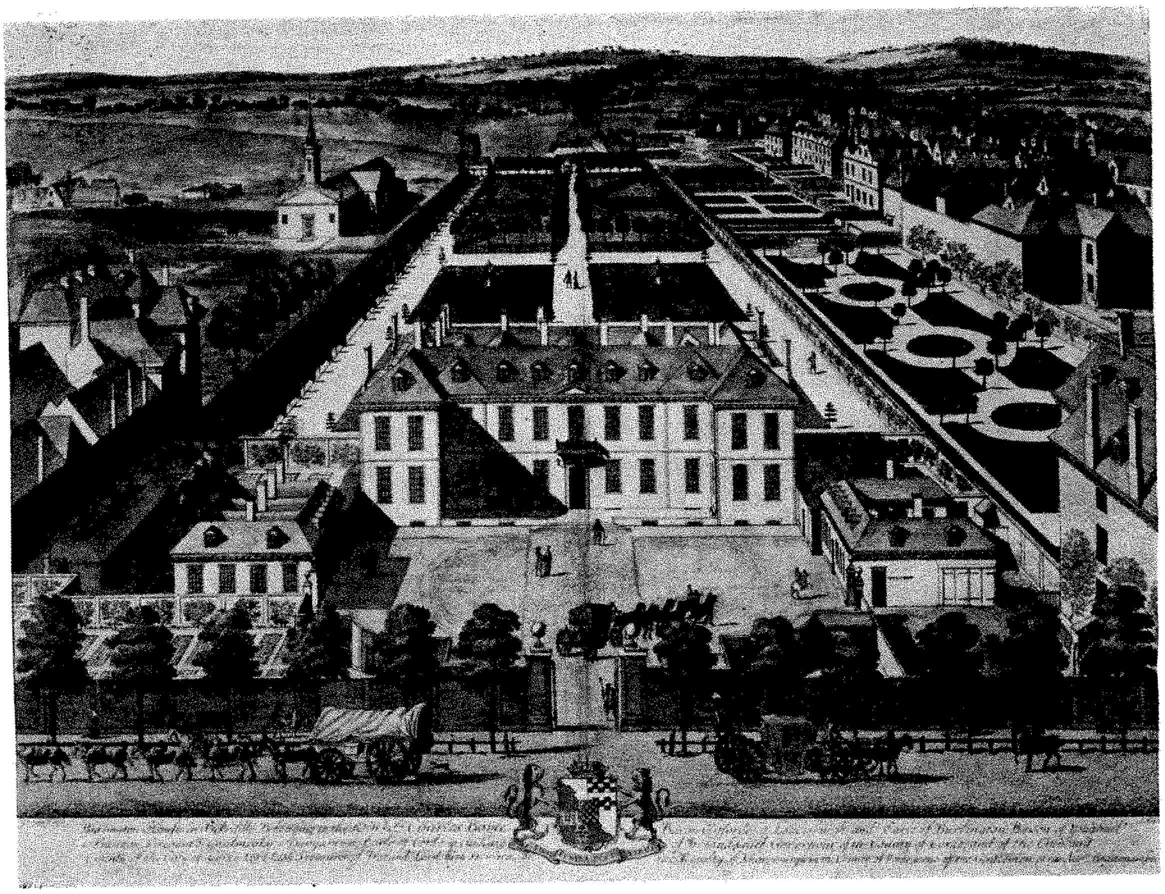

Fig. 5. Old Burlington House

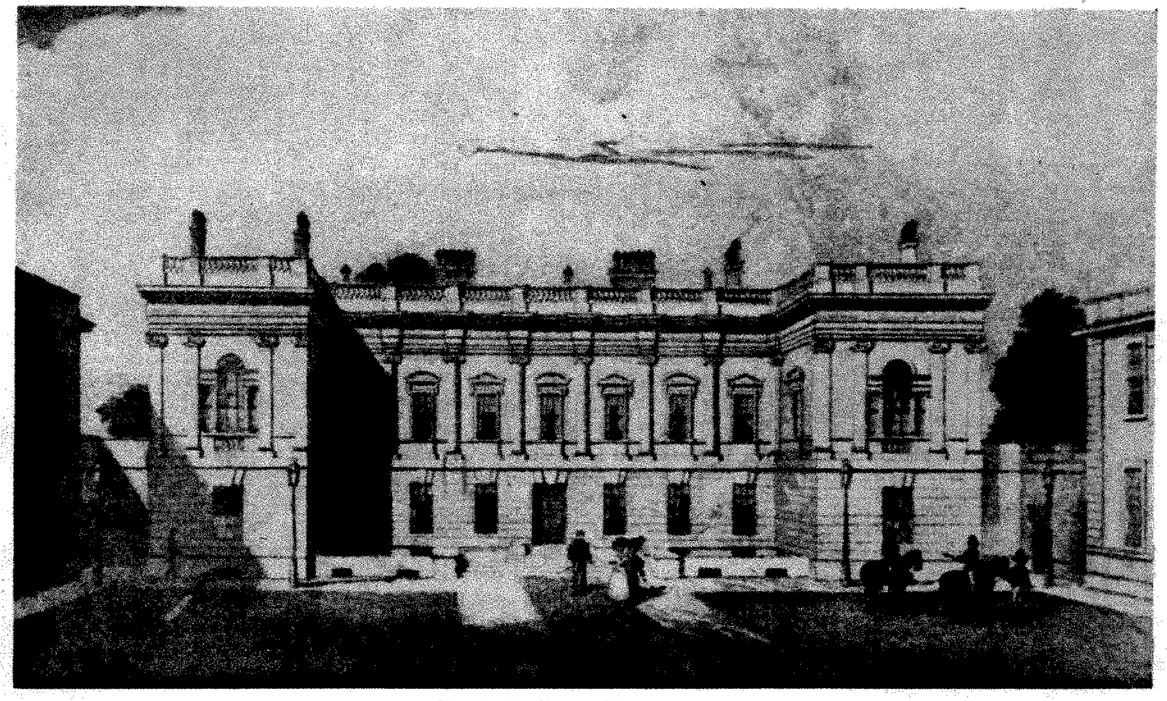

Fig. 6. Burlington House in 1868

tive Secretary what the position was. He told me that a plan had been produced by the Ministry of Works in 1960 for sharing out the space in Burlington Gardens, which was about to be evacuated by the Civil Service Commission, among the scientific societies and others. The plan was considered to be inadequate by Council, and the Ministry of Works was asked for other suggestions. In December 1960 the Executive Secretary placed on my desk an article which had appeared in *The Times* directing attention to the fact that as the Government did not propose to build a new Foreign Office on the site of Carlton House Terrace the future of the buildings there was uncertain. A spokesman for the Crown Estate Commissioners, who was apparently somewhat vague, mentioned that it might be suitable as headquarters of cultural bodies. As we all consider that even to-day science has not totally lost its place as a part of the national culture, the Royal Society seems to qualify and Carlton House Terrace was in due course inspected by the Officers (Fig. 8).

In the meantime revised plans for cutting up Burlington Gardens were produced by the Ministry of Works. The presidents of the societies around the courtyard of Burlington House were informed, and a composite inspection party invaded Burlington Gardens. Suffice it to say that the officers of the Society considered the proposed arrangements were unsatisfactory and that accommodation in Carlton House Terrace would be much preferred. Accordingly, an application was made to the Treasury for Government assistance to enable us to occupy houses Nos. 6–9. This application was refused on January 25, 1962.

There the matter might have rested if it had not been for a lunch-time conversation at Oxford, the details of which are perhaps not suitable for an address such as this. But Fellows may like to be reminded that apparently trivial events can affect their corporate life just as much as their experimental results.

For the first application to the Government the officers had prepared documents setting out why the Royal Society needed more accommodation. A copy of this was forwarded to the Nuffield Trustees, who with very little delay came forward with the magnificent offer of £250,000 towards the £500,000 which it was estimated that it would cost to transform the interior of Nos. 6–9 Carlton House Terrace for the needs of the Society.

With this backing we again approached the Treasury to see whether it would agree to pay the rent, as it has done for our premises for more than 180 years, if we raised a substantial amount for the capital cost of alterations. It agreed to consider the matter again. In the meantime further generous promises were given us—£50,000 from the Wolfson Trust, £60,000 fron the Wellcome Trust, £1,000 from Mr. L. F. A. d'Erlanger and £500 from Hambro's Bank Ltd.

In view of this backing from private sources, Her Majesty's Government, as was announced in Parliament on November 28, has agreed to pay, subject to Parliamentary approval, a sum of the order of £45,000 per annum to the Crown Estate Commissioners, who act for the Crown in respect of Carlton House Terrace. This will pay the rent and for the upkeep of the exterior of the building.

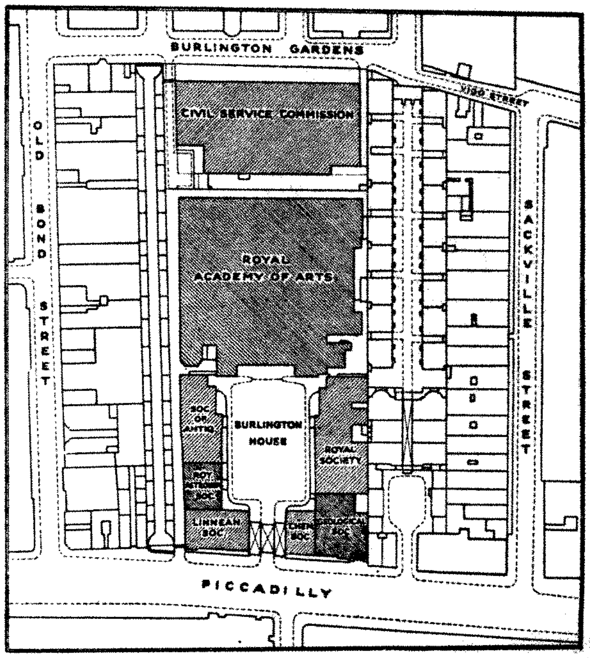

Fig. 7. Plan of Burlington House in 1943

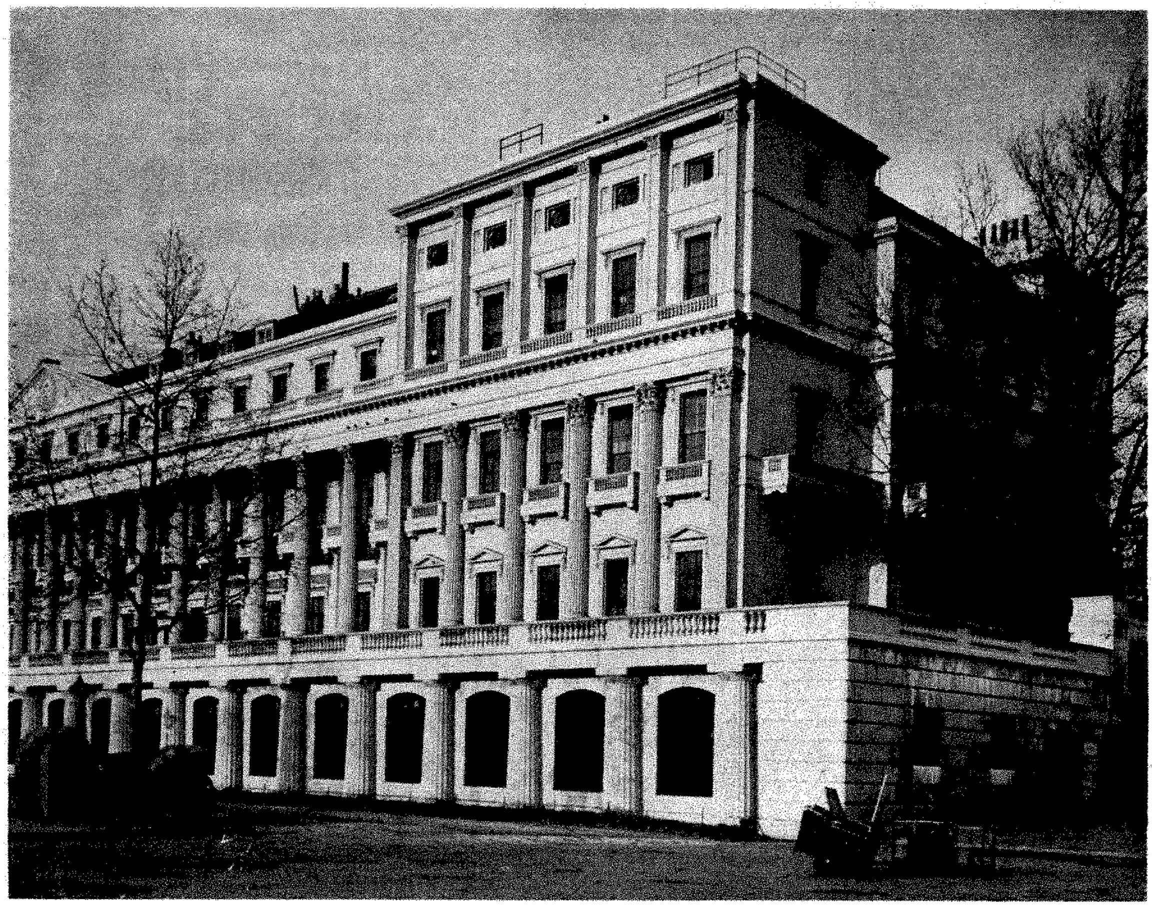

Fig. 8. Carlton House Terrace, 1963

Clearly Council has had to satisfy itself that the new accommodation will be better than the rooms we are at present occupying. In making this assessment we have had the very great advantage of securing the advice of Sir William Holford, who, as a fraternal gesture from the Royal Institution of British Architects, prepared some preliminary plans. Indeed, if it had not been for his backing of the idea that the Society could be satisfactorily housed in Carlton House Terrace, it may well be that the Treasury would have remained unconvinced of the desirability of our schemes.

Tentative plans show that in Carlton House Terrace we can have an ample number of committee rooms and one meeting room to hold about 280 people, another to hold about 100 and a third for lesser numbers. It may be possible to use the two larger meeting rooms as one if the occasion should demand this. There will, of course, be a library. There will be adequate office accommodation for the officers and the permanent staff. An innovation will be the provision of a bar and a dining room so that the social activities of the Society can be enlarged. Some six bedrooms, which can be occupied by Fellows and which may be of particular value for visitors from overseas, are planned, and also a flat for the use of the Executive Secretary.

Wren recommended, when considering his designs for a building for the Society, the provision of "a place . . . so seated in the said ground that the coaches of the members (some of which are of very great quality) may have easy access . . .". In the Carlton House site there will be some garages and parking space for additional cars—for modern Fellows without reference to their quality; and, of course, we shall occupy one of the finest sites in London.

These in bare outline are the main proposals. Fellows will, no doubt, realize that much of the negotiation associated with trying to acquire the new premises has had to be quite confidential, but three successive Councils have been kept fully informed of what was afoot. No dissentient voice has been raised. It is earnestly to be hoped that the Fellows will accept the new arrangements if they can be completed as being a substantial improvement in the Society's resources, although we shall all have regrets at leaving our present splendid library and council room.

Negotiations are still proceeding with the Crown Estate Commissioners on some architectural arrangements. Until these are completed no agreement can be initialled. We are not unhopeful of a successful outcome.

We are all immensely grateful for the extraordinarily generous response to our appeals by the Foundations and individuals I have mentioned, but it should not be forgotten that we still have at least £100,000 to collect for the adaptation of the building, and continuous efforts are being made to find this. If any Fellows can aid in bridging the gap this would be a signal service to the Society.

The generosity of the Foundations would have been of no avail but for the very substantial and continuing undertaking by Her Majesty's Government to pay the rent and outside upkeep of the new accommodation. This is not only very welcome and generous assistance in itself but it is a splendid recognition of the important part the Royal Society still has to play in the nation's scientific life.

In undertaking the present negotiations, the position of numerous scientific societies, both those now around the courtyard of Burlington House and those founded more recently, has been kept in mind. Some societies are in dire need of space to be able to carry out their functions, for in many instances the premises now occupied are quite insufficient and often occupation is of a temporary nature. It is clearly the duty of the Royal Society to assist other societies in this matter in any possible practicable manner.

At the present time there are some schemes on foot to provide London with what might be called a conference centre which among other things would contain auditoria in which individual scientific societies could hold their meetings if they so desired and which would be invaluable for international gatherings These schemes vary from the grandiose to the inadequate, but it is possible that if all scientific societies could agree to support the idea of a building in the nature of a conference centre something might be accomplished This matter is under consideration by the officers

In an ancient society it is perhaps easier to look backwards than forwards, but in the rapidly changing world in which we live it becomes urgent to adapt ourselves to the prevailing scientific environment Perhaps new and elegant accommodation will give us a base from which the Society can move forward into the exciting times that await us

As Fellows can see from the annual report of Council, the activities of the Society have been maintained and indeed they have had to be increased in view of the turmoil surrounding the reorganization of science and technology This has thrown a great burden on the secretaries in particular It is with regret that we part with an able, amusing and energetic biological secretary, Sir Lindor Brown I am grateful to him, for he has been of the greatest assistance to me personally and has, on many occasions, propped me up when I clearly did not know what I was doing He has served the Society not only by his wise advice in its internal affairs, but also by acting as its representative on many external bodies The surviving officers will all miss him and not least for the anecdotes with which he has cheered us up from time to time

The work of the secretaries has been somewhat lightened by the so-called active vice-presidents Sir Gordon Sutherland has held this office for two years and is now retiring He has been of very great help to us and particularly in directing attention, through his Committee on Emigration, to the seriousness of the loss of our scientists and technologists I would like now to thank him for all he has done for the Society and for science in a wider context

It remains only for me to welcome the new biological secretary, who is just beginning to realize the strenuous nature of his new office, but he is, I am happy to say, a very vigorous man [*Nature*, 200, 1049, 1963]

No year can close without recording our continued indebtedness to the Executive Secretary for his unremitting labours on behalf of the Society and its manifold interests He is backed by an able and well-informed staff, and to them also we give our sincere thanks

With the blurring of the conception of the British Commonwealth one of the functions of the Society, which may become more important with the passage of time, is to see that our close associations with actively growing and sympathetic countries are fostered in every possible way In this connexion, the Executive Secretary paid a visit to New Zealand in August and I joined him in Australia I need scarcely say that we were both treated with unbounded hospitality and that our glimpses of antipodean scientific activities were greatly stimulating We hope that the close contacts we have with the Australian Academy may be strengthened by visits of a similar character at not too infrequent intervals

OBITUARIES

Prof F E. Zeuner

Prof F. E Zeuner, head of the Department of Environmental Archæology in the University of London Institute of Archæology, died on November 5 at the age of fifty-eight

Zeuner came to London from Germany in 1933 He joined the staff of the British Museum (Natural History) as a research associate in palæontology in 1934 and with the aid of a Leverhulme studentship of the London Museum, also worked on the problems of the Quaternary deposits of the Thames Valley The results of this work were later incorporated in *The Pleistocene Period*, first published by the Ray Society in 1945 In 1937 he joined the newly founded Institute of Archæology, then established in St John's Lodge, Regent's Park, as honorary lecturer in geochronology, and thus established on a systematic basis the study of human environment in the past as it had not previously been attempted After the Second World War (in which he worked with the locust control unit at South Kensington) Zeuner's was one of two chairs created by the University when it accepted full responsibility for the Institute, the term 'environmental archæology' being substituted for geochronology

Zeuner's breadth of interest was already apparent before he left Germany as a young man, and he maintained and developed this throughout his career He visited many parts of the world in pursuit of his subject, usually returning with material which then became the subject of research undertaken by himself or by his students He was associated with many foreign learned societies and institutions, and as a result of his many contacts—he was, incidentally, a good linguist—had built up a collection of separates which was invaluable to his students, who were allowed free access to it Although at times the centre of controversy, his best-known book, *Dating the Past*, demonstrates his grasp of the environmental sciences Its fourth edition appeared in 1958 and it has been translated into a number of foreign languages Among his other activities, for several years he directed the operation of the carbon-14 dating apparatus which the Royal Institution set up and maintained in Albemarle Street It was this machine, which was functioning at a time when others in Britain were having difficulties, which produced the then surprising date for the early appearance of an agricultural community at Jericho in the early seventh millennium B C Just before his death he was in process of inaugurating, with the aid of a grant from the Department of Scientific and Industrial Research, a big programme of research into sea-level and soil evidence for climatic fluctuations in the Quaternary period His last book, *The History of Domesticated Animals*, was published earlier this year (*Nature*, 198, 45, 1963)

Zeuner's work and example must have a lasting effect on the study of the past in its scientific aspects Many archæologists owe their introduction to the scientific connexions of their subject to him He was an excellent teacher, with an enthusiasm for all branches of natural history which he communicated to all who listened to him, whether in his class-room or in the field Students from many parts of the world were attracted to the Institute of Archæology by his reputation, and returned to their own lands equipped to apply his ideas to their own problems

W F Grimes

Dr Frank L Howard

Dr Frank L Howard, chief of the Pure Substances Section in the Analytical Chemistry Division of the National Bureau of Standards, U S Department of Commerce, died suddenly on October 15, at the age of fifty He was a staff member of the Bureau for more than twenty-six years

Dr Howard was born in Pueblo, Colorado, in 1913 He was educated at the University of Maryland, completing a B S in chemistry in 1934 and a Ph D in organic chemistry in 1938 He joined the Bureau in 1937 and became leader of the group engaged in synthesis of hydrocarbons During the Second World War he pursued research aimed at improving aviation petrol Following the War he turned his attention to the study of jet fuel and the phenomena of combustion He was appointed acting chief of the Engine Fuels Section in 1949, and during that same year was the recipient of the Commerce Department's Silver Medal for Meritorious Service In 1951 he was appointed chief of the Engine Fuels Section, and remained in that post until 1960, when he was appointed chief of the Pure Substances Section

Dr Howard's special fields of interest covered synthesis and purification of organic compounds, petroleum and fuel technology, combustion of fuels, distillation, and automotive antifreezes He was author and co-author of many technical publications

Dr Howard is survived by his wife, two daughters and three sons

NEWS and VIEWS

Shell's Thornton Research Centre:

Dr T. M. Sugden, F R.S.

Dr T M Sugden has been appointed research director, Thornton Research Centre, Chester Dr C B Davies will continue to be director, Thornton Research Centre The Thornton Laboratories are the largest of the five research laboratories operated by "Shell" Research, Ltd, in the United Kingdom The work of the Thornton Laboratories is concerned with basic and applied research related to oil products Dr Sugden has been a reader in physical chemistry in the University of Cambridge In this capacity he has been responsible for a major contribution to high-temperature chemistry by the development of flame photometric techniques for studying controlled traces of metallic elements and their compounds in flame gases These techniques proved to be extraordinarily powerful, allowing the development of methods of measuring the stability of many simple compounds of metallic elements at high temperatures, of investigating new types of chemiluminescent reactions, and of determining rate constants for the reactions by which free radicals recombine after their production by chain-type processes

Some five years ago, Dr Sugden and his collaborators developed a mass spectrometer capable of sampling ions directly from flame gases Many interesting species, some positively and some negatively charged, were shown to be associated with the flames of hydrogen and hydrocarbons, with and without metallic additives Apart from being of great interest to students of chemical kinetics, these results have a practical importance in rocket and magnetohydrodynamics technology All Dr Sugden's work has been characterized by determining the essential chemical features of complicated reacting systems and submitting them to quantitative examination by new methods

The Prix Jecker

Dr. Léo Marion, F R S.

Dr Leo Marion, vice-president (scientific) of the National Research Council, Canada, has been awarded the Prix Jecker by the Academy of Sciences, Paris, for his work on the structure of alkaloids Dr Marion was born in Ottawa He gained an honours B Sc in 1926 and an M Sc in 1927 from Queen's University and a Ph D degree from McGill University in 1929 The same year he began his career with the National Research Council of Canada, continuing in the field of organic chemistry, principally alkaloids, on which he carried out his post-doctorate work at the University of Vienna in 1934–35 Since 1947, Dr Marion has served as editor-in-chief of the *Canadian Journals of Research* and, from 1952 until 1963, as editor of the *Canadian Journal of Chemistry* He also serves on the editorial board of other scientific journals He became head of the organic chemistry section of the Division of Chemistry in 1943, director of the Division of Pure Chemistry in 1952, senior director in 1960, and vice-president (scientific) of the National Research Council in 1963 Dr Marion has many honours to his name, including fellowships of the Royal Society of London, the Royal Society of Canada, the Chemical Institute of Canada (of which he is a past-president), l'Association Canadienne-Française pour l'Avancement des Sciences, and the Chemical Society of Great Britain, and membership of the American Chemical Society Other honours for his contributions to the field of alkaloid chemistry include the Médaille Léo Pariseau of l'Association Canadienne-Française pour l'Avancement des Sciences, the Palladium Medal of the Chemical Institute of Canada, and the Gold Medal of the Professional Institute of the Public Service of Canada

Founded in 1851, the Prix Jecker has been awarded, since 1857, to the author of the most useful work on organic chemistry, or to the chemist whose collective works have contributed most to the progress of organic chemistry The recipient receives a monetary award of 6,500 French francs (1,300 dollars)

Geography in the School of Oriental Studies (University of London)

Prof C A. Fisher

Prof C A Fisher, head of the Department of Geography in the University of Sheffield since October 1959, has been appointed to the newly created chair of geography in the School of Oriental Studies in the University of London A graduate of the University of Cambridge, he first developed special interests in the geography of south-east Asia and far-eastern regions during the Second World War, when he was on active service in Malaya and, later, from 1942 until 1945, a prisoner of war in Japanese-controlled Thailand These regional interests he has since developed, he has published numerous papers in various journals on aspects of the regional and political geography of eastern Asia and was a joint editor of the text, "Geographical Essays on British Tropical Lands" More recently, in a volume of some eight hundred pages, he has contributed a major work on the social and political geography of south-east Asia, scheduled for publication in January 1964 In 1962 he led the British delegation of geographers attending the regional conference on south-east Asia, organized by the International Geographical Union at Kuala Lumpur In 1961 he visited Japan in an extended tour, at the invitation of the Japanese Foreign Office, and in 1962 he was appointed as the first director of the Centre of Japanese Studies now attached to the University of Sheffield

The Defence (Transfer of Functions) Bill

The Defence (Transfer of Functions) Bill, which received its second reading in the House of Commons on November 21, is intended to implement the proposals of the White Paper published in July to establish a unified Ministry of Defence Although in moving the second reading Mr P Thorneycroft, the Minister of Defence, emphasized the importance he attached in the new organization to having scientists built in the administration and with the military at every level, so that the scientists were not merely considering purely scientific problems but putting forward their ideas on many aspects of strategy and challenging the established views, there was little comment on this aspect in the debate. Mr. N. Birch expressed serious misgivings about the continuance of the office of Chief of the Defence Staff, preferring a secretariat organized rather on the lines of that established by Lord Hankey and Lord Ismay. Mr. Aubrey Jones also appeared to hold rather similar views, referring to Lord Hankey's staff of the Secretariat of the Committee of Imperial Defence. Apart from this doubt as to whether the Minister of Defence and also the Cabinet Office might not require strengthening on some such lines, it was left for Sir Harry Legge-Bourke to stress the importance in the new structure of the Chief Scientific Adviser. However, he was more concerned that effective control should be political, though he thought that the changes were in the right direction and, like Mr. R. T. Paget, welcomed the prospect of bringing scientific and technical skill into all Government departments, believing that this would facilitate speedier action. In replying on the debate, Mr. J. Hay, the Civil Lord of the Admiralty, strongly upheld the importance of scientific advice being available at all stages of the policy-making process in defence.

Potential Scientific Manpower

In a written answer in the House of Commons on December 11 the Financial Secretary to the Treasury, Mr. A. Green, gave the number of full-time students in universities at the beginning of the autumn terms in 1961–63 as 111,385, 116,610 and 124,002, respectively. Of these, 12,209, 13,273 and 15,323, respectively, were in social studies, 28,082, 30,791 and 33,212 in pure science, 16,934, 16,652 and 18,183 in applied science, 12,424, 12,875 and 12,892 in medicine, and 2,028, 2,101 and 2,013 in agriculture and forestry. Full-time students in colleges of advanced technology on courses leading to recognized qualifications in the same terms numbered 9,098, 10,346 and 11,871, respectively; of these, 5,451, 6,138 and 7,205, respectively, were in technology, 3,040, 3,602, 4,103, respectively, in science, and 607, 606 and 563 in arts and social studies. Of 35,109 first-degree and first-diploma students entering universities for the first time in October 1963, 4,915 were in social studies, 9,416 in pure science, 5,357 in applied science, 2,726 in medicine and 560 in agriculture and forestry. For October 1962, the corresponding figures were 10,470, 4,121, 9,060, 4,872, 2,717 and 594, and for October 1961, 10,180, 3,932, 8,433, 5,118, 2,530 and 560. Of the 4,481 first-year students in the colleges of advanced technology in October 1963, 2,523 were in technology, 1,542 in science and 416 in arts and social studies; for October 1962, the corresponding figures are 4,081, 2,326, 1,422 and 333, and for October 1961, 3,458, 1,983, 1,165 and 308.

The Plant Varieties and Seeds Bill

The Plant Varieties and Seeds Bill, which received its second reading in the House of Lords on November 26, deals first with the rights of plant breeders and, secondly, regulates transactions in seeds and seed potatoes. As Lord St. Oswald, Joint Parliamentary Secretary to the Ministry of Agriculture, Fisheries and Food, explained in moving the second reading, the Bill as a whole originated in the reports made by the Committee on Transactions in Seeds in 1957 and 1960. The first part provides essentially a scheme for encouraging plant breeding and also derives from the International Convention for the Protection of New Varieties of Plants, to which the Government was signatory two years ago, subject to ratification after discussion in Parliament. The provisions of the Bill follow closely the arrangements proposed in the Committee on Transactions in Seeds report (Cmnd. 1092) of 1960 and grants the plant breeder a form of proprietary rights in his new variety. These are such that when the breeder has succeeded in registering the variety and has given it a distinguishing name, he alone, during the period of protection, has the right to grow it for producing seed or other reproductive material for sale, and the right to sell such material, except under licence from the breeder. The Bill also provides wide co-active powers by means of the issue of compulsory licences to prevent unreasonable restriction. Consent of the breeder will not be required for use of his variety for further breeding or research. For these purposes the Bill establishes the Plant Variety Rights Office as a semi-autonomous body standing in much the same relation to the Agricultural Departments of the United Kingdom as the Patent Office does to the Board of Trade.

The second part of the Bill is largely concerned with measuring, entrusting to regulations certain of the details written into the Seeds Act, 1920, and making the statutory control more flexible. The essential principle that the seller of seeds should give an adequate and reliable description of his goods to the buyer is retained and strengthened, particularly by the civil warranty provisions of Clause 17. A further Clause enables the Agricultural Ministers to make regulations controlling the import of certain kinds of seed, when necessary, to safeguard Britain's indigenous strains against deterioration by admixture and cross-pollination, or to prevent the import for sale of seed unsuitable for growing in Britain. The Agricultural Ministers are also empowered jointly to prepare an index of names of plant varieties for use in connexion with the sale of seeds and to require new varieties of plants to undergo performance trials before they are put on the market. In replying on the debate, Lord St. Oswald referred to the valuable work of the National Institute of Agricultural Botany and said that the Bill, which was generally welcomed in the debate, was an attempt to support the Institute's work.

"New Courses for New Students"

An address, "New Courses for New Students", delivered by Prof. H. Rée, of the University of York, at the annual conference at Margate to a meeting of Grammar School Teachers has been issued as a booklet by the National Union of Teachers (*New Courses for New Students*. Pp. 12. London: National Union of Teachers, 1963). Prof. Rée was concerned with the effect on the universities, particularly the new universities, of the immense increase in the demand for university education, and he believed the reason for changes in university courses, as well as in sixth-form courses, lay largely in the attitude of the sixth-formers themselves. The new sixth-former was much less dependent either on his parents, or on teachers, or on any of the older generation, than in the past, and Prof. Rée believed that the sixth-former resisted the compartmentation of his studies and the barrier between arts and the science sides. The new universities were attempting to deal with this situation and to provide world citizens rather than local citizens. At York the aim was to limit the number of studies offered and students were encouraged to take one main subject and another subsidiary to it—about two-thirds of the time being spent on the main subject and one-third on the subsidiary. Where this subsidiary course was education, it was not designed for those necessarily becoming teachers but rather to help introduce the undergraduate to the world in which young people were growing up—the youth clubs, the youth employment service, the juvenile courts, etc. This was a general feature of the new universities; another was the determination to ensure direct contact with teachers and eliminate the "nine to five" students. While it was hoped to secure that all students had at some time in their university life the experience of living together in groups in colleges or halls of residence, it was not intended to eliminate living in 'digs' or flats. Another problem which the new universities were facing, and in which experiment was needed, was that of the social uncertainty of the student this might be particularly difficult while the new universities were still small

Computers in Industry

A VALUABLE service to all who are interested in the use of computers in industry and commerce has been performed by the Library of Watford College of Technology Following a symposium, which was held at the College during September 1963, under the auspices of the Watford and District National Productivity Year Committee, two booklets have been prepared which should be useful to many people in industry and commerce The first, *A Select Bibliography on Computer Applications in Commerce and Industry*, has been prepared by C R Randall to show the uses of computers over a wide range of industries References are to books and articles in journals and are up to date The bibliography is intended for readers who are not computer specialists but who wish to obtain a basic knowledge of computers and applications in their own specialist fields The second, *A Directory of Computer Service Bureaux in the United Kingdom*, has been prepared by J T Graham, and gives information about the geographical coverage of many bureaux, their charges, the services they provide, whether or not there are penalty clauses for work not completed on time, and the advisory and technical research services available The main gap in coverage is the computer time available from governmental and educational establishments throughout Britain The booklets may be obtained from the Hertfordshire County Council Technical Library and Information Service, Hatfield, Herts

The National Central Library

THE forty-seventh annual report of the National Central Library, covering the year ended March 31, 1963, refers to progress with the foundations of the new buildings and to a considerable increase in applications for inter-library loans to 98,690 (91,311 in 1961–62)—the highest number recorded for ten years (Pp 24 + 3 plates London The National Central Library, 1963) While the easier type of request, chiefly for current British books, is now dealt with locally in the regional system, the demand for the more difficult type of material such as older works, those in foreign languages or published in the United States and elsewhere, continues to increase However, the Inter-lending Department succeeded in satisfying some 77 per cent of the applications, compared with 78 per cent in 1961–62 Of the satisfied applications, 15,743 were from university libraries 10,341 from special outlier libraries, 2,504 from Government departments and 4,066 from overseas Besides the 15,743 loans just noted made by or through the National Central Library to university libraries, the university libraries made 17,855 loans at the direct request of the National Central Library and lent a further 16,381 as members of regions to libraries in that region or to libraries outside their region Loans to libraries overseas totalled 3,443, and 2,686 items were borrowed—the corresponding figures for 1961–62 were 3,699 and 2,550, 603 photocopies were supplied and 936 obtained (633 and 786 in 1961 and 1962) Acquisitions by purchase totalled 7,902 volumes (1,011 for adult class purchases), 6,891 being current British Government publications, 636 American books and 628 works in foreign languages Catalogued books are now estimated at 214,000 with some 46,000 uncatalogued The Treasury grant was increased from £75,000 in 1961–62 to £82,500, including £6,500 for renting a building at Woolwich Arsenal, which was formally occupied in November 1962 as an overflow bookstore, and which will facilitate the later acceptance of larger acquisitions of material in foreign languages and older British books The Executive Committee, however, considers that the Library's income still falls far short of what is needed for it to function efficiently as a national lending library and centre of library co-operation

Melting Points of the Metal Oxides

Compilation of the Melting Points of the Metal Oxides, by Samuel J Schneider, deals comprehensively with the literature on the melting points of the metal oxides (National Bureau of Standards Monograph 68, October 10, 1963 Pp 31 U S Government Printing Office, Washington, D C 25 cents) It includes a critical evaluation of the published data as well as the designation of certain preferred values Chemists and physicists, particularly those involved in high-temperature applications, will find this Monograph especially valuable It represents the first step in a programme recently initiated by the National Bureau of Standards to re-evaluate these melting points The programme tentatively includes the acceptance of previously published values after experimental verification, as well as accurate determinations of ill-defined or completely unknown melting points Monograph 68 presents the melting points of 70 metal oxides as given in the literature published up to January 1963 It gives both the original melting point and the equivalent value based on the International Practical Temperature Scale of 1948 Information on pertinent experimental details, such as the method of temperature measurement, purity, furnace type and environmental conditions, is included The ultimate aim of the National Bureau of Standards programme is to secure national and, it is hoped, international recognition of the melting points of several specific oxides for use as calibration standards

Radioactive Fall-out

RECENTLY a report has been published by R S Cambray and Miss E M R Fisher, of the United Kingdom Atomic Energy Authority, entitled *Radioactive Fallout Short-lived Fission Products in Air and Rain, August 1962–April 1963* (*AERE-R*4384 Pp ii + 32 London H M S O. 1963 5*s* 6*d* net) This report is the most recent of a series, extending over several years, and covers the period following the tests carried out by the United States in the Pacific, which started in April 1962, and the U S S R tests of 1962 The amounts of total beta, barium-140, iodine-131 and zirconium-95 activity were estimated in atmospheric dust and rain-water derived from five stations in Great Britain, and in troposphere samples, collected by aircraft over the eastern Atlantic Brief notes on the sampling media and methods are included The American tests gave no significant amounts of barium-140, but this isotope was detected fourteen days after the resumption of testing by the U S S R It is interesting that there was a considerable increase in the amount of barium-140 washed out in snow, in late December and early January, without a correspondingly marked increase for zirconium-95, in addition, the debris arrived from the testing site in a very few days No cause is suggested for this phenomenon All the data with which this report is concerned are tabulated in considerable detail, and graphs are also included where applicable

Drugs and the Health Services

Two recent publications have directed attention to the central part played by drugs in the development of an effective health service The first, issued by the Association of the British Pharmaceutical Industry, London, is purely factual and shows that, contrary to popular belief, the percentage of money expended on pharmaceutical services related to total National Health Service expenditure has shown no significant change over the past ten years (*Facts on Drugs Information on Drugs and the National Health Service* Pp 16) 70 per cent of to-day's prescriptions could not have been written in 1935; the drugs did not exist Antibiotics, which were only made available in the 1950's, now account for 25 per cent of the drug bill The second, issued by the Office of Health Economics, is mainly concerned with the place of the general practitioner in the National Health Service and shows how his position has altered with the development of drugs (*The Personal Health Services a Perspective of the General Medical and the Pharmaceutical Services* Pp 31. 2*s*) As Lord Taylor has said, "To-day the practitioner in the gloomier slum practice can treat pneumonia more effectively than the most eminent specialist was able to do before the War" The most important development in the future should be more concentration on personal preventive medicine Early detection of such diseases as cancer and diabetes is now possible The publication states that general practitioners need improved facilities to help them carry out this early diagnosis

Antibiotics in Food and Feedstuffs

At the instance of the Joint Expert Committee on Food Additives of the World Health Organization and the Food and Agriculture Organization, the World Health Organization convened a committee to examine the public health problems likely to arise in connexion with the increasing use of antibiotics in animal feeds as growth promoters, for food preservation and in plant disease control The Expert Committee appointed has recently reported on its findings and conclusions in a booklet entitled *The Public Health Aspects of the Use of Antibiotics in Food and Feedstuffs* (Technical Report Series No 260 Pp 30 Geneva World Health Organization, London H M S O , 1963. 1 Sw fr , 1*s* 9*d* , 0 30 dollar) The report points out that most of the antibiotics used in food preservation or added to animal feedstuffs are of low toxicity, and, provided regulated quantities are used, the quantities likely to be present as residues in food are very small The danger exists, however, that penicillin, for example, may cause allergic reactions in humans already sensitized by medical treatment Chloramphenicol is in a special category, as fatal damage to the bone marrow has occurred in patients treated with therapeutic doses The Committee believes that further research is desirable in this field The rapid spoilage of meat in hot climates might, for example, be averted if tetracyclines were used, either by giving the animal pre-slaughter injections, or by treating the carcass The report stresses that such uses should be regarded as an exceptional and temporary measure pending the eventual provision of adequate refrigeration Two useful annexes to the report summarize the practices in different countries in relation to the use of antibiotics in animal feeds and for food preservation

Farm Forestry

Farm forestry plays an important part in land use in Sweden, and during 1953–60 an economic study of this subject was conducted in three localities—south, centre and north Sweden (*Kungl Skogshogskolans Skrifter* (*Bulletin of the Royal School of Forestry, Stockholm*), Nr 39 *Bondeskogsbruket · Ekonomisk Undersokning Grundad pa Bokforing 1953–1960* (*Farm Forestry in Sweden an Economic Study 1953–1960*) Av Th Streyffert och Chr von Malortie Pp 207 Stockholm Skogsbiblioteket, Skogshogskolan, 1963) Farm woodlots occupy almost half the forest area of Sweden and some of them are in the best forest area, namely, south Sweden The practice of farm forestry is an excellent example of integrating different land uses, and the forest properties are regarded as a means of increasing the income of the farmers In fact, the law prohibits the selling of forest land where it is needed for the support of the farm This investigation has produced some interesting statistics, but care should be exercised in interpreting them The woodlots examined were those where the owners were keen enough to undertake the large amount of record work necessary, and this meant that, on the whole, they were the best managed Therefore, the statistics may be considered as above average It was revealed that there was a tendency to overcutting of the prescribed yield in the smaller forests and it is suggested that the lower yield per unit area from the larger forests is due to the owners not being in such need for the money or the labour force being fully occupied with normal work But efficiency seems to be better on the larger properties where a higher rate of return is recorded As is to be expected, there are divergences from averages and many of these are due to the woodlots being under the personal management of the owners This investigation should concern not only the forest economist but also anyone interested in the integration of agriculture and forestry

Archæology in Ontario

Bulletin No 184 of the National Museum of Canada consists of a detailed report of the excavation of the Donaldson site by J V Wright and J E Anderson (*The Donaldson Site* (Anthropological Series No 58) Pp viii + 113 (26 plates) Ottawa Queen's Printer, 1963 1 50 dollars) The site is located in the Bruce Peninsula of Ontario, and traces of the settlement here include middens, a cemetery and house foundations The cemetery yielded both single and multiple inhumations in pit graves, some accompanied by personal ornaments Two house structures, demarcated by post-holes, were recovered, these were rectangular, the largest approximately 25 ft by 15 ft , and supported in all by more than 100 posts No trace of rebuilding was noticed, and some of the interior posts probably represent a sleeping platform Pottery from the middens belongs to the Saugeen Focus of the early Middle Woodland period, *c* 500 B C The stonework includes projectile points, scrapers and choppers, and copper objects were rare The material seems to show elements allied to other Woodland complexes, and is representative of an economy comparable with the northern Algonkians of historic times

Earthwork on Overton Down, Wiltshire

A recent report of a research committee of the British Association for the Advancement of Science describes the construction of a ditch and bank of chalk in Wiltshire, built partly with primitive tools, partly with modern equipment (*The Experimental Earthwork on Overton Down, Wiltshire, 1960* An account of the Construction of an Earthwork to Investigate by Experiment the way in which Archæological Structures are Denuded and Buried Pp viii + 100 + 8 plates Edited by P A Jewell London The British Association for the Advancement of Science, 1963 25*s* , 4 50 dollars) The object of the exercise, carefully outlined in meticulous detail in this book, is to allow archæologists both of the immediate and of the distant future to record through observation and excavation the development of the monument, the degree of erosion and denudation of the bank, and the degree and manner of silting of the ditch This evidence should be of great importance in the interpretation of sections obtained during the excavation of prehistoric and early historic monuments A number of objects, including textiles, food, flints and potsherds, have been buried in the bank, and future excavation will show how the various materials have reacted to the conditions of burial The first of a number of sections has already been cut, although the report on this will not appear until it has been combined with another excavation in 1964

Joseph P Kennedy, Jr Foundation Awards

The Joseph P Kennedy, Jr Foundation was established in 1946 by former Ambassador Joseph P Kennedy in memory of his son, Lieut Joseph P Kennedy, Jr The Foundation engages in a programme of support of scientific research, care and treatment in the area of mental retardation Major research projects have been established at Johns Hopkins University, Massachusetts General Hospital, Harvard University, Stanford University, the University of Wisconsin, George Peabody College, and the Kennedy Memorial Hospital in Brighton, Massachusetts Educational, diagnostic and treatment centres are located in New York City, Washington, Chicago, and Santa Monica, California In 1962, a programme of International Awards was instituted by the Foundation to recognize outstanding contributions in the field of mental retardation and to support activities in this field Awards are made in three general 'areas' (1) *Scientific Research Award*, to an investigator who has made outstanding contributions to the knowledge of mental retardation in the biological and behavioural sciences, (2) *Service Award*, to the individual or group developing outstanding programmes in the identification, care, rehabilitation, or education of the mentally retarded, (3) *Leadership Award*, to a civic leader, public official, author, or any other person whose activities on behalf of the mentally retarded have awakened the public conscience or led to increased individual and community effort Awards will be in amounts of 5,000–25,000 dollars. In addition, up to 50,000 dollars will be awarded for the furtherance of current or proposed programmes More than one Award may be offered in a single 'area' Institutions, organizations, and individuals working in the field of mental retardation are invited to send nominations to the Foundation These nominations should include biographical information, *curriculum vitae*, bibliography, and all pertinent supporting data Nominations received by August 1 will be considered for the current year's Awards, which will be announced in December Further information can be obtained from International Awards, the Joseph P Kennedy, Jr Foundation, 1413 K Street, N W , Suite 306, Washington 5, D C , to which nominations should be sent

1963 Awards

PROF L S PENROSE, Galton professor of eugenics, the Galton Laboratory, University College, London, has been awarded the Scientific Research Award The Service Award is to be shared by Dr R P L Lafon (Montpellier) and Dr G F Powers (Yale) Senator Lister Hill (Alabama), Representative J E Fogarty (Rhode Island) and Governor B T Combs (Kentucky) are to share the Leadership Award

Bursary for British Women Engineers

THE Caroline Haslett Memorial Trust is offering a bursary to assist the representation of British women engineers at the first International Conference of Women Engineers to be held in New York in June 1964 The sum of £250 will be made available for this purpose, and will be awarded to a British woman engineer, or will be shared by two, depending on the decision of the interviewing panel Application forms can be obtained from the Secretary, Caroline Haslett Memorial Trust, 25 Foubert's Place, London, W 1, and should be completed and returned by January 31, 1964 Applicants should be qualified in any field of engineering or should be pursuing a recognized training in engineering They should be prepared to make a real contribution to the Conference by reading a paper or leading a discussion, and to give some lectures in Britain after the Conference In 1960 the Trust sent two women engineers to study the training and employment of women engineers in the U S S R

The Emmie Clough Scholarship

THE Royal Horticultural Society is offering a scholarship provided out of a bequest from the late Mrs Emmie Clough to enable a girl to take a course of training in horticulture which would otherwise be beyond her means The scholarship, valued at £352 a year, will commence in September 1964 It will be open to women between the ages of eighteen and thirty and will be tenable for two years at Studley College, Warwickshire Candidates will be required to have attained a standard of education which will permit them to take full advantage of the course of study, and should normally have completed, or be prepared to undertake, such periods of practical training in horticulture as may be considered necessary The form of application, which can be obtained from the Secretary, should be completed in the candidate's own handwriting and should be returned so as to reach the Secretary, Royal Horticultural Society, Vincent Square, London, S W.1, not later than February 10, 1964

Atmospheric Radiation

THE International Radiation Commission of the International Association of Meteorology and Atmospheric Physics is holding a conference at Leningrad during August 10–15, 1964 There will be both invited and contributed papers on a wide variety of topics of current interest in the field of "Atmospheric Radiation". It is hoped to include in the programme sessions on infra-red spectroscopy of the atmosphere, theory of radiative transfer in planetary atmospheres, energy balance of the Earth's atmosphere, including (*a*) experimental investigations of the radiation field in the free atmosphere, and (*b*) radiation problems as related to atmospheric dynamics and the general circulation, radiation climatology, surface and network instrumentation Further information can be obtained from Prof J London Department of Astrophysics and the Atmospheric Sciences, University of Colorado, Boulder, Colorado; or Prof M I Budyko, the Main Geophysical Observatory, M Spasskoya 7, Leningrad *K*-18 Prof. Budyko is chairman of the local arrangements committee

Announcements

PROF E CHARGAFF, professor of biochemistry at the College of Physicians and Surgeons, Columbia University, has been awarded the Charles Leopold Mayer Prize of 80,000 N F by the French Academy of Sciences, for his work on nucleic acids

A MEETING of the Food Group of the Society of Chemical Industry will be held in the University of Liverpool on January 16 The programme will include "Whaling" by Mr C E Ash Further information can be obtained from the Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London, S W 1

A MEETING of the Food Engineering Panel of the Society of Chemical Industry will be held in London on January 22 The programme will include "Dehydration other than A F D ", by Mr G Evans Further information can be obtained from the Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London, S W 1

A ONE-DAY symposium on "Chemical and Nutritional Aspects of Heated Fats", arranged jointly by the Oils and Fats Group and the Food Group of the Society of Chemical Industry, will be held at the Imperial College of Science and Technology, London, on March 25 Further information can be obtained from the Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London, S W 1

THE one hundred and thirty-fourth course of Christmas lectures for young people will be delivered by Prof Ronald King on "Energy" The lectures will include "Energy in Atoms and Moles" (December 31), "Electrical Energy and Magnetism" (January 2), "Energy in Waves" (January 4), "Energy Deep Inside the Atom" (January 7), "Persuading Energy to do the 'Right' Thing" (January 9) Further information can be obtained from the Royal Institution, 21 Albemarle Street, London, W 1

MEASURING AIRBORNE DUST AND MIST

AN international colloquium on this subject was arranged jointly by the Staubforschungsinstitut des Hauptverbandes der gewerblichen Berufsgenossenschaften, Bonn, and the Institut National de Recherche Chimique Appliquée, Paris, it was held on October 22–23 at Freiburg (Breisgau) and was attended by about 60 scientists and engineers. The programme was divided into three sections, the first of which was concerned with number and mass concentration and the distribution of particle size. Introductory speeches were made by Prof. A. Winkel (Bonn) and A. P. Avy (Paris).

Dr. F. Hartogensis (The Hague) discussed the influence of microscopic techniques on the number of particles counted and outlined a case for the use of a well-defined system to eliminate the considerable variations in the numbers of fine particles which were visible. There was little evidence on the liability of 0·5μ particles to cause silicosis, but there was no doubt that large numbers of much finer particles were found in silicotic lungs.

The error in mean dust concentration as a function of the number of measurements, based on a log-normal distribution, was evaluated by J. Juda (Warsaw) and could be applied to gaseous pollutants. He also spoke of a method of size analysis based on pressure measurements up to 3 mm water while particles were sedimenting in liquid. Size analysis by measuring the light scattered by individual particles, while airborne, was possible with apparatus described by J. Bricard and J. Pradel (Paris). A very uniform zone of light was traversed by a jet of aerosol particles which scattered light at 90° into a microscope provided with a photomultiplier cell. An advantage of the apparatus was that the aerosol did not have to be diluted so that natural clouds of liquid particles could be measured, unexpectedly, fine liquid and solid particles had been found in city fogs which formed at 90 per cent relative humidity, the saturation deficiency being due to sulphur trioxide.

The use of membrane filters for mine dust was explained by H. D. Bauer (Bochum), and H. Gessner (Zurich) had a new sedimentation apparatus for size analysis by weighing fractions. A. Berner and O. Preining (Vienna) presented a new calibration of the 'Cascade Impactor' which they used for sampling atmospheric radioactivity, on account of its ability to handle a large volume of air. W. Stober (Gottingen) explained a theory of the deposition of particles in a conical aerosol centrifuge.

The Stokes diameter of a particle, evaluated from its sedimentation rate, is smaller than the projected area diameter, which is assessed microscopically. New measurements of the dust penetrating a sedimentation chamber between horizontal plates had been made, using a thermal precipitator, by W. Walkenhorst (Bochum), who demonstrated that the ratio varied from 1/1·3 to 1/2·2 for glass quartz, talc and coal, and exhibited a considerable scatter in any one sample of dust.

W. Matla (Heerlen) presented a number of correlations between the quartz content and ash of airborne dusts which showed that the easily determined ash value was a good indication of the amount of quartz in the dusts. Before laying down permissible limits of dust concentration, due consideration would have to be given to the standardization of measuring techniques which at present varied widely, although the principle of selective sampling for the elimination of the coarser airborne dust was generally accepted.

The second section, dealing with selective sampling, was opened by Dr. C. N. Davies (London), who showed how a curve of lung retention against particle size could be derived by considering all the available distributions of airborne dust, and of dust recovered *post mortem* from the lungs, which had been obtained by electron microscopy. The British 'Hexhlet' selective dust sampler worked on a simple falling velocity separation formula which did not represent selection in the human bronchi and bronchioles but could be redesigned to do so. A cyclone separator, described by H. Breuer (Essen), collected much finer dust which resembled lung dust more closely.

M. Landwehr (Bochum) had used a pre-impinger to separate the coarse fraction of dust, while finer particles, below 5μ, passed through and were collected in a scrubber or on a membrane filter.

Two papers dealt with practical aspects of the British 'Hexhlet'. R. J. Hamilton (Isleworth) explained how it had been found necessary to increase the separation of the selector plates to 1·2 mm to avoid pick-up of deposited particles and to reduce the width of the entry to prevent external wind effects. K. G. Schmidt (Bonn) was critical of the performance of the instrument and had been troubled by corrosion of the aluminium plates which carried over into the fine fraction of dust.

The final section covered recording dust apparatus and opened with a description by A. P. Avy and M. Benarie (Paris) of a novel device in which an aerosol was sucked through an orifice so that the particles struck a microphone and could be recorded. F. Hartogensis had found that a compensated photoelectric smoke recorder was of some use for measuring industrial dust and had also used a paper-stain recorder. M. Raillière (Paris) compared the principles of measuring sideways or forwards scattered light and E. Walter (Bonn) claimed that photoelectric recording of dust concentration was possible for concentrations ranging from less than 1 mg/m^3 to 30 mg/m^3.

Messrs. Leitz (Wetzlar) announced a new Tyndallscope incorporating a photomultiplier which obtained its high voltage from a potted transistor flip-flop condenser circuit. This remarkably sensitive dust recorder retains the sensitivity and portability of the well-known visual instrument.

The recording of aerosol particles by the contact E.M.F. which is developed on impact has been developed by R. Prochazka (Vienna and Munich) and A. Schutz (Bonn). The former described a finished instrument in which wall collisions as the aerosol passed through a tube were amplified, concentrations down to 0·5 mg/m^3 at flows up to 60 m^3/h and particles down to 0·2μ could be dealt with. The apparatus of Schutz operated on collisions with a metal wire and was even more sensitive, when the dust concentration fell below 0·1 mg/m^3 fluctuations developed owing to the ion content of the atmosphere which depended on temperature and humidity. It could advantageously be preceded by a selection device when used for recording industrial dusts.

The use of Zeleny tubes to establish the size distribution of fine atmospheric particles marked with thorium *B* was described by G. Madelaine, J. Bricard, J. Pradel and F. Billard (Fontenay-aux-Roses and Paris). Using this aerosol the efficiency of a filter paper was found to change from 99·997 per cent to 99·993 per cent when the particle size increased from 10^{-3} to 10^{-1}μ. W. Coenen (Bonn) deposited small ions on dust particles and recorded the dust by the ion current.

The meeting concluded with a paper by W. Neuwirth (Freiburg), who had investigated correlations of atmospheric pollution with prevailing weather conditions.

The papers which were presented at Freiburg will be published in *Staub* early in 1964 and another meeting will be held in Paris next autumn.

C. N. Davies

GENERATION, DETECTION AND PROPERTIES OF COHERENT RADIATION OF WAVE-LENGTHS LESS THAN 1 MM

THE autumn meeting of the British Radio Spectroscopy Group was held at Bournemouth, Hampshire, during September 24–25 The meeting was concerned with the generation, detection and properties of coherent radiation of wave-lengths less than 1 mm Nineteen papers were presented during three sessions while the fourth session was taken up with a visit to the Quantum Physics Division of the Signals Research and Development Establishment, Christchurch, Hampshire

Mr R J Lees, director of the Signals Research and Development Establishment, who gave the address of welcome to the 130 delegates, comprising approximately 45 from the universities, 55 from industry and 30 from Government service, saw the essential function of the meeting to enable the delegates to exchange ideas on mutual interests so forming cross-linkages between the various sections of this wide field

The nineteen papers presented can be divided into four general groupings, eleven on generation, two on detection, three on spectroscopy and three concerned with gaseous lasers As can be seen, the generation of sub-millimetre radiation attracted the most attention

M. G Convert (Compagnie Générale de Télégraphie sans Fil) discussed the main design features beam geometry, beam velocity and construction of the elements that have to be considered in the development of a carcinatron The power output, which depends approximately on the reciprocal of the frequency squared, is limited by the imperfections in them together with any ohmic losses Results were presented of output power against wave-length for a range of values. In particular the 0 5-mm carcinatron gave a few milliwatts and had a 10 per cent tuning range.

Dr K D Froome (National Physical Laboratory, Teddington) outlined the design of his plasma–metal junction harmonic generator It rectifies and therefore generates harmonics by field emission from a liquid platinum cathode due to the proximity of a very dense plasma This plasma is formed in an argon–hydrogen atmosphere at high pressure and has an ion density that has to be kept to less than 10^{20} in order to avoid back conduction When the junction was driven with 10 W at 8 5-mm, 0 3-mm radiation, the twenty-ninth harmonic, was generated

The construction and operation of such a generator as a tunable source in a high-resolution sub-millimetre spectrometer was described by Mr. J Knapp (Queen Mary College) It was found not practical to use it in an automatic scan system Dr A J Bastin (Queen Mary College) reported measurements made by a number of workers, including himself, of atmospheric absorption in the sub-millimetre region These measurements showed that atmospheric absorption was due to (1) water vapour broadened by nitrogen collisions; (2) water droplets of varying radii, (3) oxygen, ozone and other trace gases, (4) collision-induced absorption between oxygen and nitrogen atoms It was commented that more experiments were needed in which some attempt had been made to match path-length to absorption coefficients

Mr G S. Waters (Signals Research and Development Establishment) described the construction and operation of an optical line-of-sight communication link using a helium neon laser on 6328 Å as source Measurements were made comparing the laser as a source with a mercury-arc lamp, both being shone 'backwards' through a mirror telescope over 1,300 yd The results showed that the spatial coherence of the laser made the laser superior to the arc lamp for ranges longer than 300 yd The laser's narrower line-width seemed to be only of secondary importance Dr D C Laine (Keele) examined the feasibility of an ammonia maser oscillating at 0 125 mm on the $J = 4$, $K = 3$ to $J = 3$, $K = 3$ rotational transition A relation was derived giving the minimum number of molecules required per sec for oscillation threshold The substitution of values into this relation gave that the number required was a factor two thousand times larger than the number needed in the microwave case This factor can only be obtained by the use of multiple beams

Dr J G Baker (Bristol) discussed the spectroscopy of short-lived free radicles and gases in the lower millimetre and sub-millimetre regions A free-space absorption cell suitable for the observation of electric and magnetic rotational transitions, many of which fall in these regions, was described together with a superheterodyne system of detection. Mr A W Horsley (Standard Telecommunication Laboratories, Ltd) discussed two possibilities for generating sub-millimetre radiation using bulk non-linear properties of semi-conductors The first rested on charge density gradients and electric field gradients in the semiconductor giving rise to harmonic currents The second involved the mixing of axial modes in laser beams by an extension of Pantell's centimetre wave mixing techniques Mr. C H Carmichael (Signals Research and Development Establishment) proposed the use of a Fabry–Perot etalon within the parallel mirror resonant cavity of a laser to suppress the emission except within the narrow pass bands of the etalon Then with a laser material, the fluorescence line width of which is 10 cm^{-1} or greater, the plate separation of the etalon can be chosen to yield frequencies, which, when mixed in a suitable non-linear system, will yield sub-millimetre radiation

Mr I B Bott (Radar Research Establishment) described the construction of a tunable source of millimetre radiation 0 93–2 mm Electrons, when injected into an axially symmetric magnetic field, undergo cyclotron resonance and the radiation emitted in a strong forward lobe is partially coherent In the case described the field was pulsed to 100 kG and remained reasonably steady for 7 msec The output at 1 1 mm was 1 mW Mr A H Beck (Cambridge) suggested that a spiralling electron beam when synchronized to an electric field having the correct time dependence should be a method of generating millimetre radiation Mr P M Robson (Sheffield) suggested that millimetre radiation could be generated by Doppler shifting radiation from a moving mirror of low-voltage electrons If the electrons were to be bunched at the matching frequency then both the electron mirror's reflectance would be increased and there would be some harmonic output Dr J V Jelley (Atomic Energy Research Establishment) discussed the use of Čerenkov radiation as a source of sub-millimetre waves A Fourier analysis of the radiation produced as electrons are fired through a dielectric shows that there is a component at a sub-millimetre frequency This component may be enhanced by bunching the electrons at the required frequency This method has produced 20 μW at 1 6 mm

Mr M A C S Brown (Radar Research Establishment) described two possible tunable detector mechanisms; one depending on changes in number of carriers and the other depending on changes of carrier mobility Both these mechanisms are suitable for use in narrow band far infrared detectors A description of the indium antimonide detector was given together with its narrow-band characteristics

Dr. M. R. Brown (Signals Research and Development Establishment) gave a brief report on the observation of infra-red quantum counter action in praseodymium doped fluoride lattices at room and liquid nitrogen temperatures. It was hoped to use the reported schemes as a basis for the development of an infra-red detector. Mr. D. M. Clunie (Services Electronics Research Laboratory) reported results of some experiments on helium–neon gas mixtures in which more power was obtained under pulsed conditions than under continuous excitation. This was attributed to the population in the laser terminal level being higher under the continuous excitation. Furthermore, by having two sections separately pulsed at 2.5 kc/s a continuous output at 0.25-W mean level was obtained. Doubling of the infra-red outputs in ammonium dihydrogen phosphate to give a yellow spot was announced. Mr. J. Smith (Mullards) reported gain measurements made in helium–neon gas mixtures using the 1.15μ laser line. It was found that the optimum gain in the negative glow region of a cold-cathode glow discharge within a hollow cathode was achieved at much higher pressure (20-mm mercury) and higher helium to neon ratios (1,280 : 1) than those used in radiofrequency or direct-current positive column excited devices.

Dr. E. L. Thomas (Signals Research and Development Establishment) explained the stimulated Raman effect and its use in the generation of radiation. When benzene is placed inside the resonant cavity of a ruby laser, stimulated Raman radiation is produced 991 cm^{-1} away from the ruby frequency. A second Raman radiation can also be generated approximately 1,982 cm^{-1} away. The sub-millimetre radiation, in this case 0.01 mm, would then be generated by mixing the Raman radiation with the ruby radiation.

Dr. D. H. Martin (Queen Mary College) reviewed the kinds of spectra that can be observed in solids with sub-millimetre radiation. These ranged from lattice absorptions in ionic lattices (30μ for lithium fluoride) to anti-ferromagnetic resonance (1.2 mm for manganous fluoride).

M. R. BROWN

THE GEOLOGISTS' ASSOCIATION

SEVERAL important geological finds made during 1963 were among the exhibits shown at the annual reunion of the Geologists' Association held in the Large Hall of Chelsea College of Science and Technology on November 2.

The most outstanding of these discoveries was the remains of a large pliosaur from the Oxford Clay exhibited by the Department of Palæontology, British Museum (Natural History). This comprised a right-hand paddle 7 ft. 6 in. in length. Many pliosaurs have been found in the Oxford Clay especially near Peterborough[1]. However, complete specimens of large pliosaurs lying *in situ* are rarely come by. It is thought their size prevented them from quickly sinking in the mud and hence they were eaten by their fellow scavengers. The pliosaur was found in the London Brick Company's clay pits at Stewartby, Bedfordshire, during June 1963, but the front half of the reptile had been taken away by the digger before the bones were noticed. Some of them were later recovered from the spoil heap by a party from the British Museum (Natural History), and the London Brick Co. has presented the remains to the Museum. It is hoped that the whole reptile will be recovered. The British Museum (Natural History) also showed dinosaurian footprints from the Purbeck, Devonian trilobites from the Spanish Sahara and cobalt pellets from the stomachs of sheep.

In 1961 the longest continuous trackways yet found were discovered in a quarry at Herston on the outskirts of Swanage, and in June 1963 after the overburden had been removed 75 ft. of trackway was exposed. Until now it has been generally assumed that these footprints were made by the herbivorous bi-pedal dinosaur, *Iguanodon*. But, as shown by the exhibit, it is apparent that the bird-like prints forming the main trackway are more akin to a bi-pedal carnivorous dinosaur, such as *Megalosaurus*.

Until recently, trilobite remains were almost unknown from the Spanish Sahara, but during oil exploration work there E. Rod collected almost 30 specimens. The best were given to the British Museum. They came from strata of the Middle Devonian and all belong to the genus *Phacops*. With the exception of a single specimen they belong to one species, probably new but related to *P. papulatus* from Morocco. The remaining specimen is a related form but is distinguished by a finer ornamentation of the test and a large number of eye facets.

S. E. Ellis (Department of Mineralogy) exhibited phosphate minerals deposited on cobalt pellets from the stomachs of sheep. The sheep is subject to a disease known as 'pining' due to a deficiency of cobalt in herbage. This is combated by either the expensive method of spraying or inserting into the young lamb's stomach a pellet of baked clay impregnated with cobalt oxide.

Ammonites and literature recently acquired in the U.S.S.R. were among the items shown by the Geological Survey and Museum. Ammonites are very important in the identification of zones or sub-zones, which are often named after them. They included the following species from the Upper Aptian of the Lower Greensand (Lower Cretaceous): *Parahoplites melchioris, Colombiceras caucasicum* and *Australiceras ramososeptatum*.

J. N. Carreck (Queen Mary College, London) showed specimens, maps, etc., illustrating copperas, as vanished Kentish industry. From about A.D. 1320 until 1914, copperas (an obsolete name for ferrous sulphate or green vitriol) was manufactured from iron pyrites occurring in the London Clay (Lower Eocene) on parts of the coasts of Essex[2], Kent, Dorset and, perhaps, Hampshire. It was used for the preparation of sulphuric acid, black ink and dye (both as a pigment and a mordant), dressing leather, as a sheep die, for the making of paints—prussian blue (ferric ferrocyanide) and spanish brown (ferric hydroxide), and after refinement was in much demand among both apothecaries and physicians. Mrs. Carreck exhibited photographs of past and present members of the Association.

Dr. G. P. L. Walker (Imperial College of Science and Technology, London) showed several xenoliths of wood collected from Tertiary basalt larvas. He explained how timber, when enclosed in basalt, chars and the basalt is consequently injected into the network of contraction cracks which result. Sometimes the charred wood survives, at other times it is fossilized, for example, replaced by zeolites, or it disappears to leave cavities in the basalt and these may afterwards be infilled with zeolites, etc.

With the west Weald earthquake of October 25 and the Glen Spean earthquake of August 31 still in the news, Dr. A. T. J. Dollar (Birkbeck College, London) exhibited a map illustrating the intensity of the quakes, together with data based on reports from observers of the British Earthquake Enquiry. Other earthquakes demonstrated in the same manner were those occurring in the County of Inverness in 1947 (ref. 3) and the Midlands in 1957 (ref. 4). Together with F. G. Berry, Dr. Dollar also showed a new hand-operated continuous coring tool with a sample core.

A. G. Nicholson showed specimens illustrating the geology of the Lizard Peninsula. These included the 'serpentine' of the local lapidaries which is the altered and attractively coloured part of bastite serpentine found chiefly at quarries near Kennack and Lizard Town, although some of the lapidaries' stock consists of beach boulders Rare invertebrates obtained from a very large 'pocket' of fossiliferous sand of the Lower Bartonian (Eocene) at Highcliffe, Hampshire, were exhibited by F. C Stinton They included a sea urchin *Spatangus omalii* and bivalves *Tellina scalaroides* and *Abra glabra* The 'pocket' was contained in a very sandy blue clay

Kingston College of Technology showed rocks collected in Aberdeenshire at the British Association Meeting and fish from the Lower Old Red Sandstone (Lower Devonian) at Kerrera, near Oban According to P R Gurr (Kingston College) and Dr L B Tarlo (University of Oxford), the fish fauna consisted of *Cephalaspis lornensis*, as well as a new species of this genus possessing long cornua projecting from the postero-lateral corners of the head shield Two new cephalaspid genera, also represented, indicated that forms with cornua were not merely primitive animals giving rise to true *Cephalaspis*, but that they had an important evolutionary development of their own

Some Tertiary mammals from France were shown by W H Bennett, including teeth of *Mastodon angustidens* from the Helvetian (Middle Miocene) and teeth and jawbone of *Lophiodon rhinocerodes*, a relative of the tapir, from the Bartonian (Eocene) Other items included casts of recently described American species of crustaceans, etc , by Mrs J I Collins, *Arcoscalpellum comptum*, a cirripede new to the Gault (Lower Cretaceous), by J S H Collins, a pyrites nodule from the chalk (Cretaceous) containing a terebratulid by A Gunner, fossil reptile remains from the Lias (Lower Jurassic) at Ravenscar by A J R Snelling, igneous and associated rocks of the Lake District by the Cumberland Geological Society, a cheap method of recording serial sections at minute intervals by F. J W Holwill (Imperial College of Science and Technology, London) and new German Devonian fossil finds, etc , by Mr and Mrs E P Bottley of the well-known geological firm of Messrs Gregory, Bottley and Co

INSTITUTE OF PERSONNEL MANAGEMENT

GOLDEN JUBILEE

THE last major event in the Golden Jubilee Year of the Institute of Personnel Management was its annual conference held at Harrogate during October 10–12 Again the attendance was about 1,000, made up of personnel and staff managers and directors from many companies throughout the world

The theme of the conference was management, productivity and industrial relations, and this was examined by Lord Shawcross in his opening address He suggested, first, that before advising industry how to organize itself, politicians should set themselves the task of organizing Government itself, for the machinery is cracking to the point of breakdown The weakest part of the organization is in the formulation of policy In the old days, perhaps up to the First World War, governmental activity was far less complex than it is to-day, and ministers with ample leisure and small departmental responsibilities were able to cope with problems reasonably satisfactorily To-day, with vastly increased occasions for governmental intervention, with problems of immense complexity and with heavy departmental pressures, this is far from the case To-day, policy is settled by debate in a Cabinet consisting of twenty-two members, each armed with a departmental brief and either tending to look at the matter mainly from a departmental point of view or expressing an opinion without much real knowledge of the subject-matter Any business run in this way would collapse Efficiency demands a much smaller Cabinet, say perhaps ten people, selected not primarily because they happen to be the heads of particular departments but because they are clearly the best ten people at the Prime Minister's disposal Among these ten people, the Prime Minister must lead clearly and firmly and accept the responsibility of being the ultimate arbiter of policy Obviously this arrangement would place on the Prime Minister a heavy burden· he would need assistance much beyond what can at present be given to him by his small private office He should have, as number two in his Cabinet, as a kind of 'chief of staff', a minister without direct departmental responsibilities, possibly the Lord President or the Lord Privy Seal, whose task it would be to assist the Prime Minister in formulating planning and assessing policies and surveying the main field of governmental activity This minister should himself have a small staff of top-level people, largely drawn from outside the Civil Service and including some possessing what politicians usually lack completely, a trained understanding of the technological age in which we live, who would help to formulate policies having first formed a political view as to what it was desirable and expedient to do

Turning to industry, Lord Shawcross said that, although there are gratifying signs of an upturn in the economy, Britain is not doing well enough Other countries have accelerated past her In the past eight years Britain's wages costs have risen about 3 per cent per annum faster than her main competitors, productivity has risen about 3 per cent slower In those years Britain's export prices went up by 15 per cent, her exports in quantity went up by 32 per cent In the same period, German prices went up only 5 per cent—but her exports rose in quantity by nearly 200 per cent

There is need for a supercharger to boost the industrial engine, and this must come from industry The Government, however, has a part to play in its planning function Government planning with knowledge of the overall economic picture ought to be of value to industry and there are things which Government can do, as varied as selective capital investment allowances, encouraging particular industries and special housing programmes and resettlement allowances, to encourage mobility of labour Subject to Government marking out the roads for advance, the self-correcting features of competitive private enterprise should not be destroyed The supercharger, however, is better management and better industrial relations leading to better productivity In the past quarter of a century there have been great improvements in standards of management Nowadays the pattern in big industry is increasingly for the boards of industrial operating companies, as distinct from holding companies, to consist entirely of whole-time executive directors who have worked themselves up to the top But the standard of management still needs to be raised considerably and management training should be organized not by industry alone, and not by the universities and technical colleges alone, but by both groups in consultation with a full knowledge of what each can provide and each needs. The crux is to enable executives to develop those qualities which make them more than merely good administrators, give them more powers of intellectual analysis and integrity and enable them to look for and assess the factors which are relevant to and on which they can take firm decisions and exercise clear leadership.

As usual, a series of sectional meetings at the conference provided a useful means of reviewing progress in a number of sectors concerned with improving human and industrial relationships. In discussing the merits of long-term agreements as a means of establishing better human relationships, for example, J. S. McGavin (Albert E. Reid and Co., Ltd.) suggested that, with the possible exception of the agreement in the building trade, long-term agreements differ from the old merely in that horse-trading occurs at greater intervals. The chief motive in negotiating a long-term agreement seems to be to reduce the frequency of negotiations which can occupy a large amount of the time of both employers and Trade Unions and lead to deterioration in relationships. There is now, however, a new force in evidence which must begin to exert an influence: the setting up of the National Economic Development Council and the National Incomes Commission. Particularly significant is the retrospective examination of any agreement which is part of the terms of reference of the National Incomes Commission. Private bargains between employers and Trade Unions may be subjected to close scrutiny based at least on some of the facts that tend to be forgotten in the heat of bargaining.

Among the disadvantages of long-term agreements are that, in a trade recession, profits may drop while labour costs are automatically increased, there is an increase in tension when an agreement comes to an end and a new one is to be negotiated, with the possibility of a strike if the negotiators are unwilling to make concessions, the experience of employers in the United States is that automatic wage adjustments under a long-term agreement have little effect on productivity but that there is some intangible or moral value, especially in disputes over technological change and its effects on remuneration. Not all trade unionists are keen on long-term agreements and some see them as seriously lessening the Trade Union bargaining position.

R. F. Marshall (Associated Electrical Industries, Ltd.) examined the Government proposals for industrial training as a means of improving Britain's inadequate supply of skilled manpower. The objects of the training proposals are to enable decisions on the scale of training to be better related to economic needs and technological developments, to improve the overall quality of industrial training and to establish minimum standards, to enable the cost to be more fairly spread. Among criticisms of Government proposals made by Marshall were that the provision of industrial training places in the appropriate numbers and of appropriate quality is an essential feature of the training arrangements for the technicians and technologists. The National Council for Technological Awards sent a comment on this to both the Minister of Education and to the Minister of Labour: "Industrial training plays as important a part in the training of a technologist as it does in the training of a craftsman and a technician. While a large number of firms have given considerable assistance to colleges in providing industrial training for students following courses leading to a Diploma of Technology, the further expansion of courses will require a substantial increase in the number of training places in industry".

It is proposed that the majority of firms scheduled within a defined industry shall contribute a levy and thus be directly involved, even though some of the firms do not actively contribute to training. The Minister of Labour has suggested that it would be uneconomical to extract the levy from very small firms. This point of view is criticized on the grounds that it is these very small firms which drain away skilled labour from the larger units. The industrial training boards proposed by the Minister will have the responsibility for all aspects of training, not excluding management training. Doubts have been expressed about the capacity of a board which, having been set up to promote craft training, would be able to consider and promote training at other levels of employment where standards have yet to be set. Marshall also made a number of suggestions to ensure that levies are fairly made in industrial organizations and also for the efficient running of the Industrial Training Boards.

In a plenary address, Prof. O. Hahn-Frend, professor of comparative law (elect) in the University of Oxford, examined the question of whether increased legal intervention in industrial relations is desirable in Britain at the present time and, if so, in what directions. He distinguished between four different kinds of such intervention which may be called: auxiliary, prohibitive, regulative and remedial. The law may seek to promote collective bargaining and the observance of collective agreements, for example, by imposing a legally enforceable obligation to bargain (United States), by enforcing as compulsory terms of the contracts of employment the terms agreed between employers and Trade Unions (France, Germany and other Continental countries), or by creating substitutes for non-functioning bargaining machinery which at the same time operate as stimuli to collective bargaining and to the observance of agreements (Britain). In all this the law is no more than an auxiliary to collective bargaining. It does not regulate, but assists the autonomous forces of industry in doing so.

The law may (and must) mark the outer limits of the area within which hostile action in industrial relations is permissible, and prohibit certain types of conduct connected with strikes, lock-outs, etc., while permitting others. This is the only contribution the Common Law has made, and one of the main functions of legislation in Britain has been to free industrial action from the shackles of the Common Law. Even so, this prohibitory function of law can nowhere and never be dispensed with entirely.

Thirdly, the law may itself create the standards prevailing between employers and the employed, that is, their mutual rights and duties. Protective legislation concerning health, safety, welfare, legislation on hours of work, on methods of wage payments and also on minimum wages and holidays, offers examples. Outside Britain, this covers rights of tenure, that is, security of job, payment in the event of sickness or interruption of work, notice of termination of the contract and many other matters. To some extent, the recent Contracts of Employment Act is also an example. Fourthly, and lastly, the law must provide enforcement machinery, that is, administrative authorities, such as inspectors, and courts and enforcement officers to translate rights into remedies and remedies into tangible advantages. The practical value of auxiliary, prohibitive or regulatory legislation may depend on the stringency and accessibility of the remedies provided by its enforcement.

There is a strong case for improved and increased regulatory and remedial legislation, but the case for further auxiliary legislation is weak and that for further prohibitive legislation non-existent. Trade Unions and employers' associations are well able to see to the enforcement of collective agreements, provided the law does not further deprive them of the extra-legal weapons at their disposal. With the growth of non-manual at the expense of manual work (which is the result of technical developments) the area of collective bargaining may dwindle and the need for regulatory legislation may grow. So may the need for state-provided enforcement machinery, less expensive, more accessible and more rapid than the existing courts.

With regard to regulatory legislation on security of jobs and legislation on the enforcement of rights between employers and employees, Britain falls between two stools

Britain does not have collective agreements as intensive in coverage as those existing in the United States perhaps owing to the extensiveness of their scope (industry-wide as distinguished from plant-wide agreements). British agreements are less substantial than their counterparts in the United States, and, in particular, do not comprise anything like the American codes of job security and seniority or the grievance arbitration machinery through which these and other rights are enforced. On the other hand, Britain has nothing comparable with the German legislation on job security or the French principles on abusive or unfair dismissals. The Contract of Employment Act, 1963, is no more than a feeble and insignificant first step in this direction: it gives a right to a maximum of four weeks' notice after five years of continuous employment, and no power to award compensation for unfair deprivation of job. German workers and employees can claim up to one year's salary or wages by way of compensation for undue dismissal.

Similarly, Britain has neither the American pattern of grievance arbitration nor the Continental pattern of labour courts, consisting either (as in France) entirely of laymen, or (as in Germany) of a lawyer chairman, one employer and one employee with equal rights. These operate very rapidly and very cheaply, and settle many cases, and are far better adjusted to handling employer–employee cases than the existing machinery of justice in Britain.

To-day, British legislation on labour relations which, at one time, was in the van of progress, has fallen in arrears. The scrutiny of the fairness of dismissals, coupled with a power to award a right to be reinstated or to receive compensation and the creation of labour courts, are two measures necessary to promote social justice as well as the smooth operation of industrial relations.

The conference was also significant for a plea by Mr. G. R. Moxon (United Glass Ltd.), the president of the Institute, that the time had come for all bodies dealing with personnel management to re-examine their structure and organization and pool their resources in order to provide better services, particularly in projects overseas where British participation would be invaluable.

T. H. HAWKINS

SOLID-STATE CHEMISTRY

THE phenomenal growth of solid-state chemistry in the past fifteen years owes much to the joint research ventures of chemists, engineers and physicists, and the impetus for this stems largely from what has been aptly termed "the explosion in electronics", the invention of the transistor. In a paper by Dr. N. B. Hannay, chemical director, Bell Telephone Laboratories, for many years past concerned with semiconductor chemistry (*Science and Technology*, New York, October, 1963), the present position of this intriguing subject is ably summarized. The basis of this discipline is, he says, that "all solids are imperfect, fortunately, with atoms missing, misplaced, or of the wrong kind serving to bring the seemingly stolid solid to vibrant, useful, chemically reactive life". The high state of purity and crystalline perfection of some semiconductors, combined with their unique electrical properties, have facilitated the quantitative investigation of chemical processes in the solid state; they have made chemical reactions in such materials not only of great scientific interest but also to assume the importance of model systems as first principles in as yet a wide and largely unexplored field of chemical behaviour.

Many chemical interactions in semiconductors are analogous to those known and described in solution chemistry. The solvent is weakly ionized, like water, but in this case solid instead of liquid. "Just as ionization of water produces hydroxide and hydrogen ions ($H_2O \rightleftarrows H^+ + OH^-$) so ionization in semiconductors produces conduction electrons and holes (Si lattice $\rightleftarrows e^+ + e^-$) in a closely analogous way. Conduction electrons, which are not bound to any lattice atoms but wander freely through the lattice, are created when valence electrons are excited out of their normal atomic orbits by thermal agitation or by optical excitation. Holes, which simulate positively charged particles in their electrical behaviour, simply represent missing valence electrons". Several examples of reactions in semiconductors resembling those in aqueous solution are given in this paper and the analogies between them are striking. They result from the essential similarity between the hole (e^+)–electron (e^-) equilibrium in semiconductors and the hydrogen–hydroxyl equilibrium in water. It is indicated that both equilibria are governed by the familiar law of mass action, that is, any change in concentration of reactants which are in equilibrium shifts the equilibrium in a direction that tends to neutralize the change.

As Dr. Hannay points out, there remain, apart from the 'glamorous' materials and devices already discovered in the course of these researches in solid-state chemistry, innumerable problems of major theoretical and practical importance that are still unsolved. Among these may be cited the better understanding of controls on reaction rates, diffusion mechanisms, nucleation processes, for example, as applicable to catalysis. H. B. MILNER

CENTENARY OF THE BIRTH OF W. H. YOUNG, F.R.S.

WILLIAM HENRY YOUNG was born on October 20, 1863. He entered Peterhouse, Cambridge, in 1881, was fourth Wrangler in 1884 and a Fellow of Peterhouse from 1886 until 1892. For thirteen years he coached for the Mathematical Tripos, a profitable but arduous occupation. He was an excellent coach, particularly with less than excellent pupils, but he gave, so far as mathematics was concerned, no sign during this period of the fertile originality that was to come.

In 1896 he married Grace Chisholm, a mathematician of no mean ability herself, a Wrangler of Girton and the first woman D.Phil. of Göttingen. Distinguished as her own work was, her greatest service to science was the influence she had on her husband, which, in the first instance, led him in 1897 to give up his Cambridge practice and devote most of his time to research. From then on, the family home was abroad, at first in Göttingen, later in Switzerland. Although Young spent some months in each year from 1901 until 1923 in some paid activity, mainly teaching mathematics in Britain, mathematical research (unpaid) dominated the rest of his life. In 30 years he published more than 200 papers. Young burst out in British pure mathematics like a supernova. He was elected a Fellow of the Royal Society in 1907.

His productivity is the more astounding in that it started so late and that his first work failed to bring him the credit it deserved. About this time, Lebesgue arrived at his definition of an integral. Young, working independently, arrived at a definition differing in form from Lebesgue's, but essentially equivalent. Lebesgue, however, was first, and it is called the Lebesgue integral. Fortunately, Young's name is attached not only to recondite theorems in the theory of Fourier series and the theory of surfaces, but to more than one result in undergraduate analysis, where the clarity of his mind created a new simplicity and a new elegance.

He raised a large and talented family. He died in 1942, alone in Lausanne, separated by the accidents of war from his wife and family. At a seminar on November 5, at Imperial College, Sir Graham Sutton (one of Young's pupils), Dr J C Burkill and Prof. J Proudman spoke on Young and his mathematical work, including his methods of teaching, and the centenary was commemorated in the evening by a small dinner at his old club, the Athenaeum. (See also *Nature*, 150, 227, 1942.)

H D URSELL

SHIFTING SAND BANKS OFF LOWESTOFT

LITTLE is known about the origin or stability of sand banks although some are serious hazards to navigation around the southern half of the British Isles. Accordingly, publication of a detailed account of 6 square miles of sand banks off Lowestoft* is a most welcome addition to knowledge, for both practical and academic reasons. It is fitting that this study was carried out by a member of staff of the department of the Admiralty which surveys the sea-floor and draws up navigational charts.

The method of approach adopted by Mr Cloet was to compare the 44 detailed surveys made between 1835 and 1962, using a standard datum. From these surveys he prepared figures showing the maximum and minimum depths detected at any place and then derived a further figure showing the maximum known changes in thickness which can be expected. Such changes may reach even as much as 80 ft. It is suggested that the channelled surface of maximum depth is made of bedrock or relatively immovable material such as pebbles.

Much of the analysis is concerned with a demonstration of the stability or motion of channels and sand banks and the smaller features associated with them. It is shown that the rate of movement of a feature need not be uniform and can vary with depth. Their direction of growth is particularly interesting since it is apparent that they approach Lowestoft both from north-north-west and south-south-west, and interfere off the harbour entrance. There are indications that their direction of growth corresponds to the direction of sand transport by tidal currents though the occasions of transport, and the relative importance of sea-waves cannot be revealed by such a study.

Diagrams are numerous, but it is a pity that so few are self-explanatory. It is rather unfair that only some of the localities mentioned in the text are shown on the figures, for not everyone has ready access to detailed Admiralty charts, or knows the region as well as Mr Cloet. A much more serious criticism concerns the difficulty of identifying the ornament and of matching it with that in the key on figures, such as 3–5. Such a style of reproduction is false economy.

LONG-RANGE WEATHER FORECASTS

THE present state of knowledge does not permit a satisfactory theoretical solution to the problem of the general circulation of the atmosphere, nor to the associated problem of forecasting for long periods ahead. Because of the practical importance of long-range forecasts, many national meteorological services attempt to deal with the problem empirically, mostly on a regional basis and, of course, avoiding over-precision. No country depends entirely on one method of prediction, but makes the most of a variety of aids towards a solution. In any country, however, there tends to be a concentration of effort along particular lines because of the work involved. A short description of the methods adopted by different meteorological services has recently been published[1] by the German Weather Service, following the report[2] published in 1962 by a working group of the Commission for Aerology (World Meteorological Organization).

Some methods used are statistical and objective, and can treat a wide range of observational material in attempts to find correlations between future weather and available measurements. Regression equations have been used, for example, in forecasting the Indian Monsoon, but simple and multiple correlation tables also have their uses. The French, German and Russian weather services make great use of statistical methods. The various chosen predictors may be values of anomalies of pressure, temperature or rainfall, or may be concerned with weather types, solar influences, or with the interactions of atmosphere and ocean. Climatological probabilities and persistence tendencies must also be taken into account.

Another of the favoured methods makes use of analogous situations from the past, and assumes that an existing weather situation will develop in the manner followed by a similar previous situation found in weather records. The finding of analogues is essentially the basis of the British method, which compares present and past patterns of temperature anomalies over a large part of the northern hemisphere, and also examines the sequence of weather charts during the month over the British Isles as well as the monthly mean pressure chart over the northern hemisphere. A forecast can then be made when a number of analogous situations lead to similar sequels. If their sequels are different, then the most likely sequel is chosen in the light of additional arguments which may be based on the limits of the polar ice-cap, sea temperatures, snow cover or some marked anomaly of the general circulation.

Other methods depend on extrapolation. For example, the United States Weather Bureau examines mean circulation patterns and extrapolates these by normal forecasting methods, thus obtaining an indication of the most likely main paths of depressions and anticyclones during a period. From this indication can be produced charts showing anomalies of temperature and rainfall. Other extrapolation methods make use of periodogram analysis and extrapolate any regular variations found in a chosen predictor, though some methods used in the United States make use of a theoretical formula for obtaining the speed of movement of a wave pattern.

Many of the methods are adaptable to the electronic computer, and the enormous possibilities of modern computing are causing some reconsideration of previous ideas on the use of statistical data. The computer also makes possible various researches on the use of dynamical theory to obtain a numerical prediction.

In all this work there is great need for international co-operation by the exchange of scientific papers, data and forecasts Verification tests are difficult to carry out even with the facilities of a meteorological service, but the various countries show a very similar (rather low) standard of success. The British Meteorological Office, on the basis of experience with experimental forecasts during the past decade, claims no more than forecasts which are significantly better than chance when considered over a period of time From December 1963 the forecasts will appear in a new Meteorological Office publication[3], though the methods used are still experimental The publication consists of a single sheet, one side of which contains climatological data for Britain for the forecast period, while the other side contains data for the month just past, followed by weather prospects for the coming month Used with understanding, these forecasts may be of value to various interests in industry, commerce and agriculture.

ACCELERATION OF SINKING RATES OF RADIONUCLIDES IN THE OCEAN

By PROF CHARLES OSTERBERG, DR. ANDREW G. CAREY, JUN., and DR. HERBERT CURL, JUN

Department of Oceanography, Oregon State University, Corvallis

ZIRCONIUM-95–niobium-95 and cerium-141–144 were detected by γ-ray spectrometry in two samples of sea-cucumbers collected off the Oregon coast west of Newport in April 1963 Sea-cucumbers of the genus *Paelopatides* were found at 2,800 m, 65 miles offshore, *Stichopus californicus* were taken in 200 m of water 25 miles off Newport The γ-ray spectra of these two benthic sediment feeders were remarkably similar, except for the lower zinc-65 peak in the spectrum of *Paelopatides* sp (Fig 1) Since these animals are bottom feeders, the presence of short half-lived fission products in the deeper sample suggests a more rapid sinking rate for fall-out particles in the sea than would be expected from purely physical processes

All benthic animals were collected with a 22-ft shrimp-type otter trawl. Samples, preserved in formalin and freeze-dried, were ashed at 500° C overnight 12 c.c. of ash were counted in the well of a 5 in × 5 in sodium iodide (Tl) crystal, the signal from which was resolved with a 256-channel pulse height analyser

Recounts of both samples over a 114-day period indicated a 66-day half-life[1] for ^{95}Zr–^{95}Nb The calculated half-life of the $^{141-144}$Ce mixture gradually lengthened due to the decreasing percentage of 33-day ^{141}Ce compared to 282-day ^{144}Ce Potassium-40, the naturally radioactive isotope of potassium, has a very long half-life and showed no significant changes in activity over the period of observation

Particles of fall-out radionuclides exist in a wide range of sizes, but Sisefsky[2] found particles larger than 4 5μ from worldwide fall-out to be very rare These particles would not be likely to sink in sea-water at a rate faster than that determined from Stokes's law According to the calculations of Carritt and Harley[3] based on Stokes's law, a 10μ spherical granite particle would require almost a year to sink to 2,800 m and a 1μ particle would require 100 years, in the absence of turbulence

There are few measurements of the settling rate of fall-out particles in the ocean Near Eniwetok immediately after a nuclear test, Lowman[4] observed that radioactivity moved downward in the surface mixed layer (about 75 m thick) at 2 5 m/h Below the thermocline, it increased to 10 m/h At these high rates, a particle would sink to 2,800 m in approximately 12 days Such high sinking rates are probably due to the predominantly large particles present in local fall-out[5], most of which have a diameter greater than 25μ

Sugihara and Bowen[6] reported that cerium-144 in the Atlantic Ocean, away from local fall-out, is removed from surface waters on particles sinking at about 100 m per month, or slower Fall-out travelling at this rate would require 28 months to reach 2,800 m The half-life of zirconium-95 is only 65 days, and the peak due to this isotope in the spectrum of our deep sample is a prominent one Clearly the zirconium-95 in our collecting area, also far from any nuclear test site, must have descended at a rate much faster than 100 m/month

The similarity of the fall-out peaks (^{95}Zr–^{95}Nb and $^{141-144}$Ce) for the two samples (Fig 1) suggests a very short transit time downward for these radionuclides Unfortunately, however, absolute values for settling times require many assumptions For example, we may assume that both deep and shallow sea-cucumbers should have the same ^{40}K ^{95}Zr–^{95}Nb ratios, and attribute the small observed difference to radioactive decay The larger ratio for the sea-cucumbers from 2,800 m would result from a decay time (that is, transit time) of seven days

We might also assume that both groups of animals should have equal amounts of ^{95}Zr–^{95}Nb (per unit weight) if they were feeding together at the same depth However, the deeper sample was observed to have less ^{95}Zr–^{95}Nb

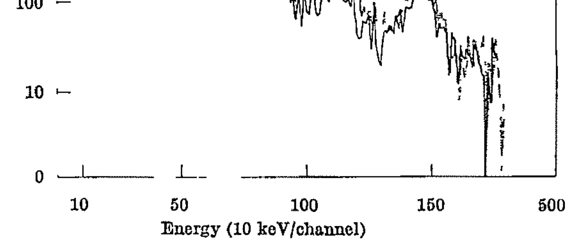

Fig 1 Gamma-ray spectra of the sea-cucumbers *Paelopatides* sp and *Stichopus californicus* To avoid the confusion of overlap, the spectrum of the sea-cucumber from 2,800 m has been displaced downward slightly Zirconium-95–niobium-95 and cerium-141–144 are from fall-out, zinc-65 is principally from the Hanford, Washington, reactors, and potassium-40 is the naturally radioactive isotope of potassium 100 min count, , 200 m, —— 2,800 m

than the shallow sample The observed difference in activity, if attributed to radioactive decay while the fall-out settled to the greater depth, yields a transit time of about 12 days Although neither assumption is known to be valid, the small difference in the spectra points to the need for a process which is capable of carrying fall-out down to the ocean depths before appreciable radioactive decay can occur

We suggest that biological processes are responsible for the relative abundance of fission products in deep bottom feeders Particulate fall-out radionuclides are known to be concentrated by herbivorous copepods, euphausiids, salps and pteropods[7-9] These zooplankton, which make up the bulk of second trophic level marine organisms, ingest fall-out particles attached to microscopic plants in the surface waters of the ocean Unassimilated radionuclides are released in fæcal pellets, which, because of their greater size, sink rapidly. The biological turn-over time for these radionuclides is quite short Chipman[10], in a laboratory experiment, observed that the copepod *Tigropus californicus* excreted 97 per cent of ingested cerium-144 in one day. He concluded that fission products in general were poorly absorbed from the digestive tracts of zooplankton Apparently most herbivorous plankton are rapid 'processors' of particulate fall-out radionuclides, continually converting small particles into larger ones

Preliminary measurements of the sinking rates of fæcal pellets have been made in our laboratory by Curl (in preparation) *Euphausia pacifica*, a very abundant euphausiid, was fed diatoms (*Skeletonema costatum*) The average sinking rate for the resulting fæcal pellets ($100\mu \times 1{,}000\mu$–$500\mu \times 3{,}000\mu$) was 43 m/day Under similar conditions (still water, temperature 10° C, salinity $33^0/_{00}$) these pellets would require about 65 days to reach 2,800 m. Of course, there are many factors in the ocean which could alter the sinking rate Nevertheless, radionuclides incorporated into fæcal pellets would reach the bottom much faster than 'unprocessed' fall-out particles

Predators which feed on herbivorous zooplankton carry fission products into higher trophic levels These predators are in effect concentrating fall-out radionuclides, since most of the ^{95}Zr–^{95}Nb and $^{141-144}$Ce is not assimilated[9]. It is conceivable that the excretory products of higher trophic level organisms are in such a form as to further accelerate settling rates of these radionuclides

The ratios of ^{95}Zr–^{95}Nb $^{141-144}$Ce, which were higher in the deep sample throughout the observed decay period, indicate that more $^{141-144}$Ce than ^{95}Zr–^{95}Nb was lost during the longer transit time to 2,800 m Preferential loss could result from a slightly greater solubility of $^{141-144}$Ce, either in sea-water or in the digestive tract

Zinc-65, from atomic reactors (Hanford Laboratories, Washington) on the Columbia River, did not behave in the same manner as the fission products It was abundant in sea-cucumbers from 200 m, but much less was found in animals from 2,800 m (Fig 1), despite a longer half-life (245 days) than ^{95}Zr–^{95}Nb Unlike zirconium, niobium and cerium, zinc is present in a number of enzymes Apparently the biological turnover time for zinc is quite long, and little radiozinc reaches the bottom Either it is not readily excreted, or, if excreted, most zinc-65 is lost from fæcal pellets before they reach 2,800 m

The possibility that our samples were contaminated with fall-out either at sea or in the laboratory was carefully checked. Of the 25 sea-cucumbers taken in the deep sample, only 16 were ashed to obtain the spectrum in Fig 1 Six others were dissected, and their digestive tracts (which would not be subject to surface contamination) were analysed separately The same radionuclides were present The spectrum of seven unidentified anthozoans (sea anemones) from the same trawl showed comparable levels of ^{40}K and ^{65}Zn, but the ^{95}Zr–^{95}Nb peak was only one-eighth as high This difference would not be expected if the sample were contaminated, but is typical of the discrimination against ^{95}Zr–^{95}Nb which has been observed in some oceanic animals[9] As a further check three and one-half months later a second collection was made from 2,600 m, 145 miles offshore The levels of radioactivity in *Paelopatides* sp were lower, but evidence of fall-out was clearly present Benthic worms, which are considered to be deposit feeders, were also collected in this trawl They too contained ^{95}Zr–^{95}Nb

These observations lead us to conclude that fall-out radionuclides can reach the ocean bottom quite rapidly under certain conditions We propose that the great numbers of herbivorous zooplankton in the upper layers of the ocean are largely responsible for this phenomenon

We acknowledge the assistance of Danil Hancock, Lauren Larsen and the captain and crew of the R V *Acona* We thank Elizabeth Deichmann and J McCauley for identification of our sea-cucumbers

PALÆOMAGNETIC INDICATIONS OF AN INCREASE IN THE EARTH'S RADIUS

By DR. D. VAN HILTEN

Department of Mining, Technological University, Delft, The Netherlands

A NUMBER of authors[1-4] have proposed, mainly on geotectonic grounds, the hypothesis that the Earth's radius has increased during geological history The rate at which this increase should have taken place according to their views is depicted in Fig 3 The authors agree that the continents have not—or have scarcely—increased in area since the Palæozoic, and that the increase in global area must be sought in the formation or enlargement of the oceanic basins This implies that the distance measured along the Earth's surface between two points on the stable part of the same continent remains constant, but that the geocentric angle between these points decreases inversely proportional to the increase in the Earth's radius

Like most students of palæomagnetism, I assume that the ancient geomagnetic field had a dipole configuration From the direction of magnetization measured on rocks of one sampling site the ancient position of the geo-

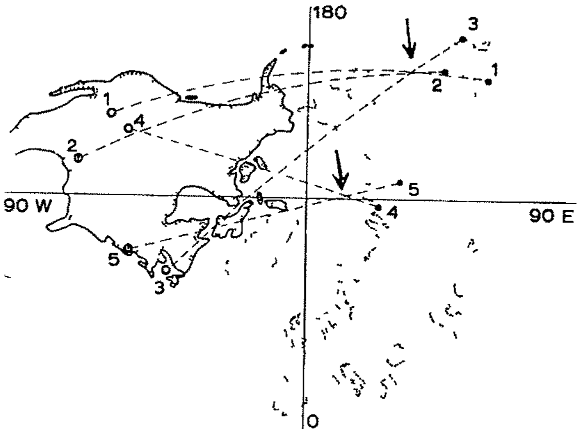

Fig 1 Carboniferous (1, 2, 3) and Triassic (4, 5) palæomagnetic data from North America in stereographic projection Sampling sites (open circles) are connected by great circles (dashed) with the corresponding pole positions (full dots), the distances between site and pole position have been calculated on the assumption of a constant Earth's radius ($R_a = R$) The scatter of the poles can be reduced by diminishing this Ra/R ratio to such a degree that the pole positions come to lie around the points of intersection (arrows) of great circles of equal geological age Numbers refer to Table 1

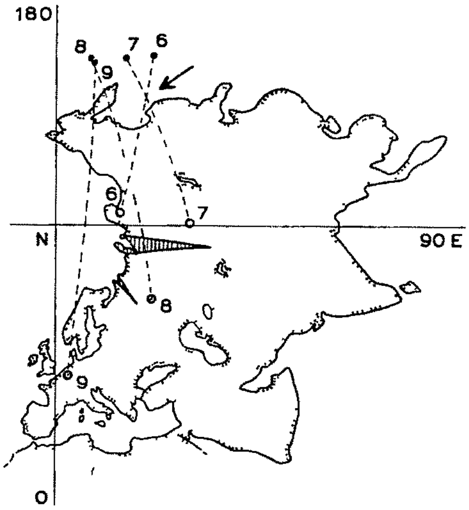

Fig 2 Permian palæomagnetic data from Siberia (6, 7), Russia (8), and western Europe (9) See also caption to Fig 1 and text

magnetic pole with respect to this sampling site may be reconstructed the declination of the direction of magnetization shows the direction (a great circle through the collecting site) in which the ancient pole was situated From the inclination (I) the ancient distance of the pole from the sampling locality can be calculated from

$$p = \frac{R_a}{R} \cot^{-1} (\tfrac{1}{2} \tan I) \qquad (1)$$

where p is the geocentric angle between sampling site and ancient pole position, adapted to the present-day radius of the Earth (R), R_a represents the ancient radius of the Earth at the time of deposition of the rocks investigated When palæomagnetic observations of equal age from two or more widely separated localities on the same continent are available R_a may be found Distinctions can be made in two different cases (1) the localities were situated on about the same ancient geomagnetic meridian, but on different geomagnetic palæolatitudes, (2) the localities were on about the same geomagnetic palæolatitude but on different geomagnetic palæomeridians

In the first case the ancient radius is known from

$$R_a = d/[\cot^{-1}(\tfrac{1}{2} \tan I_1) - \cot^{-1}(\tfrac{1}{2} \tan I_2)] \qquad (2)$$

where d is the distance measured along the Earth's surface between the two ancient geomagnetic latitude circles of the sampling sites, and I_1 and I_2 are the inclinations of the direction of magnetization measured at these localities In an earlier attempt to calculate the Permian Earth's radius, Cox and Doell[5] made use of this method; their results will be discussed here

In the second case the ancient geomagnetic pole position may be found by drawing the great circles through the sampling localities in the direction given by the declination (Figs 1 and 2) The ancient pole will be situated then on the intersection of these great circles, which are in fact geomagnetic palæomeridians From equation (1) R_a can be calculated, p being known as the distance between sampling site and point of intersection of the great circles

Scrutinizing the world's palæomagnetic record, five sets of palæomagnetic data can be found which seem favourable for an R_a evaluation (*a*) the Carboniferous of North America, (*b*) the Triassic of North America; (*c*) the Permian of Siberia, (*d*) the Cretaceous of North America, (*e*) the Permian of western Europe The first four of these sets should be classed under case 2, and the

Calculations of the R_a/R ratios required to have the pole positions coinciding with the point of intersection of the great circles

fifth set of data under case 1, as the sampling sites of western Europe are situated about in line with the ancient pole position (same palæolongitude)

Carboniferous of North America The six investigations (data from Cox and Doell[6], p 704 Nos 38, 40, 43, 45, 47, 49) are distributed over three sampling areas (Table 1 and Fig 1) The great circles intersect at one point, from where the distances p to the three sampling sites are measured. This yields three values for $R_{\text{Carboniferous}}$ (Table 1 and Fig 3)

Triassic of North America Twelve palæomagnetic investigations are confined to two sampling areas, they are (Cox and Doell[6], pp 713–718) Nos 22, 39, 79, 91, 105, belonging to sampling site 4 on Fig 1 The Nos 93, 96, 9o, 100 and 102 from Cox and Doell[6] and the investigations by Irving and Banks[7] and by Opdyke[8] are all situated in the eastern United States, the sampling site 5 of Fig 1

Permian of Siberia. The data have been taken from Irving[9] and from Popova[10] Both calculations of R_{Permian} produce about the same value (Figs 2 and 3)

Cretaceous of North America Five palæomagnetic investigations are distributed over three sampling localities (Table 1). Location 10 Cox and Doell[6], p 725, No 4, and the work by Currie *et al* [11]; Location 11· the observations of Larochelle[12]; Location 12 the results of Larochelle and Black[13] The three intersecting great circles form a triangle, which offers six estimates for the ancient polar distance p and the R_a/R ratio From their average value a Cretaceous Earth's radius of 6,027 km results

Permian of western Europe A qualitative selection was made from the numerous Permian data of western Europe Five studies were chosen because of the greater reliability of their results, due to laboratory tests in a c -fields or thermal methods, they are the palæomagnetic researches by Van Everdingen[14] (Oslo volcanics), Nijenhuis[15] (Nahe effusives, Germany), Roche *et al* [16] (Vosges volcanics), De Magnée and Nairn[17] (Poudingue de Malmédy, Belgium), and Kruseman[18] (Lodève sediments, Southern France) These authors demonstrated that a certain amount of postdepositional or recent magnetization may be present in the majority of the rocks investigated, by which especially the inclination is affected The earlier analysis of European data by Cox and Doell[5] included a high percentage of 'not-cleaned' rocks Furthermore, they envisaged also the volcanic series of the Estérel (southern France) an area which probably[19,20] should not be considered with the stable part of Europe By forming couples of the two extreme sampling sites (Oslo and Lodève) with the mid-European ones, and with one another, in total seven estimates of R_{Permian} can be made For the value of d in equation (2) the difference between the distances of the sampling sites from their average ancient pole position was taken The arithmetical mean of the seven calculations yields a Permian Earth's radius of 5,612 km (Fig 3)

Utterly inconsistent with the foregoing evidence for an increase in the Earth's radius during geological history is the coincidence of the virtual pole positions derived from western Europe and Russia[21], though their sampling sites are well on different palæolongitudes (Fig 2) Advocates of global expansion might attribute this inconsistency to the 'orange-peel' effect half an orange, squeezed to fit the flat bottom of the fruit-squeezer, will produce a number of radial tears in its outer rim Something analogous may be expected to occur at the borders of a continental slab adjusting itself to a less-curved surface, though, taking into account the slow rate of the process and the somewhat different materials involved, the tears may present themselves rather as zones of extension The more coherent blocks beside these zones perform tangential rotations, each unit moving away from its neighbour In Fig 2 some zones of extension (hatched) have tentatively been drawn between Europe–Russia–Siberia Their positions have been chosen in order to fit the geological outlines of those regions the western zone is thought to coincide with the Pechora depression[22], the eastern one with the Ob Valley, they are both areas of thick Mesozoic and Tertiary sedimentation The activity of these zones of extension during the post-Permian expansion of the globe might have torn the Eurasian poles apart, by which the expected configuration of intersecting great circles was destroyed

To summarize, it may be stated that palæomagnetic evidence (compiled in Fig. 3) seems to indicate a noteworthy increase in the Earth's radius since the Carboniferous, the rate of which agrees roughly with the hypotheses of Carey[1] and Heezen[3]

SEAWARD EXTENSION AND ORIGIN OF THE FREETOWN LAYERED BASIC COMPLEX OF SIERRA LEONE

By PROF. D. C. KRAUSE

Graduate School of Oceanography, University of Rhode Island, Kingston, Rhode Island

GEOLOGICAL and geophysical surveys of the Freetown layered basic complex of the Sierra Leone Peninsula suggest that the mass is shaped like an inverted cone or saucer of 30 km radius and that the western half is beneath the Atlantic Ocean[1] This hypothesis was tested with the echo sounder and magnetometer traverses with the R V. *Trident* of the University of Rhode Island on May 16, 1963 (Figs 1 and 2) The dense complex is characterized by four repeated sequences of troctolitic, gabbroic and anorthositic rocks considered to be igneous intrusives in which there is a generalized upward sequence from olivine-rich to plagioclase-rich rocks, but in which there is no progressive variation in the composition of the minerals The floor is concordant to the layering and dips toward the centre at 20°–30°, where examined[1] Baker and Bott[2] found that the eastern margin of the basic complex is marked by a very intense, narrow, negative anomaly of up to 2,000 gammas

Both echo sounder profiles show a submarine channel (points *C*, *F*) where the magnetic anomalies begin and show rough bottom over the zone of the anomalies The channel of profile 1 is the Pleistocene channel marking the sub-aerial course of the Sierra Leone River during the glacial lowering of sea-level based on soundings of U S N H O Chart 2344 The other channel of similar origin trends toward Sherbro River and Yawri Bay The irregular bottom over the anomalies must mark the outcrop of the basic complex or the rock overlying that body The channels were incised along the contact between the basic body or its overlying rock, and the bordering softer rock

In order to interpret the intense anomaly of profile 2, theoretical anomalies were calculated for a series of horizontal plates the thicknesses of which equalled the depth to their upper surface The plates calculated were for depths of $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, 1, 2, 4 and 8 km These calculated anomalies were used to compare a vertically sided body and a stepped, wedge-shaped body The principle of superposition was used wherein the calculated anomalies of the plates were added to one another after the relative position of plates was determined The magnetic field due to the body is assumed to be induced by the present Earth's field which here dips $2\frac{1}{2}$° N towards N 17° W The calculations are based on the method of Gulatee[3]

The vertically sided body did not fit the situation because of the high narrow negative anomaly at the contact The wedge-shaped body gives an anomaly that is much closer to that of the observed feature The interpretation indicates that the floor of the magnetic body dips 40° or less to the south along profile 1 and that the magnetized body does not extend below 4 km depth The body may be overlain by at least 100 m of relatively non-magnetic rock. The apparent magnetic susceptibility required of the rock for such an anomaly is 0 02 if all the magnetism is induced This is far too large for a natural feature Probably one half of the anomaly is due to a remnant field imposed when the igneous body cooled The assumption of direction of the magnetism in the body appears to be justified

The anomaly of the second crossing is not so great as that of the first crossing though still large A partial explanation of this probably is that the second crossing is almost at right angles to the Earth's field which should yield, theoretically, a much reduced and differently shaped anomaly The large size of this anomaly indicates structural and perhaps chemical variations within the body

An upper contact of the Freetown complex as indicated by the magnetic anomalies (points *B*, *E*) falls on circle *M*1 the centre of which is point *M* This is the same centre as derived by Wells[1] for the arcuate gravity anomalies of the complex However, circle *M*2 about this centre only poorly outlines the outcrop of the complex If circle *N*1 is drawn about a new centre *N*, a better agreement is attained for the outer eastern margin of the outcropping body as indicated by the gravity anomaly The latter circle also passes close to the submarine channels (points *C*, *F*) Points *C* and *F* are also near the actual edge of the smaller magnetic anomalies

On the basis of the foregoing observations, the Freetown layered basic complex seems to consist of two parts (1) an outcropping rock best defined by circle *N*1 with relatively local magnetic anomalies compatible with the type of rock exposed on land, (2) a highly magnetic rock defined by the intense magnetic anomalies

The intense magnetic anomalies of zones *A–B* and *A–E* of the profiles are caused by rocks which seem to have no outcropping counterparts on the Peninsula The correspondence of loci of the intense magnetic and the gravity anomalies suggest that a very large, saucer-shaped,

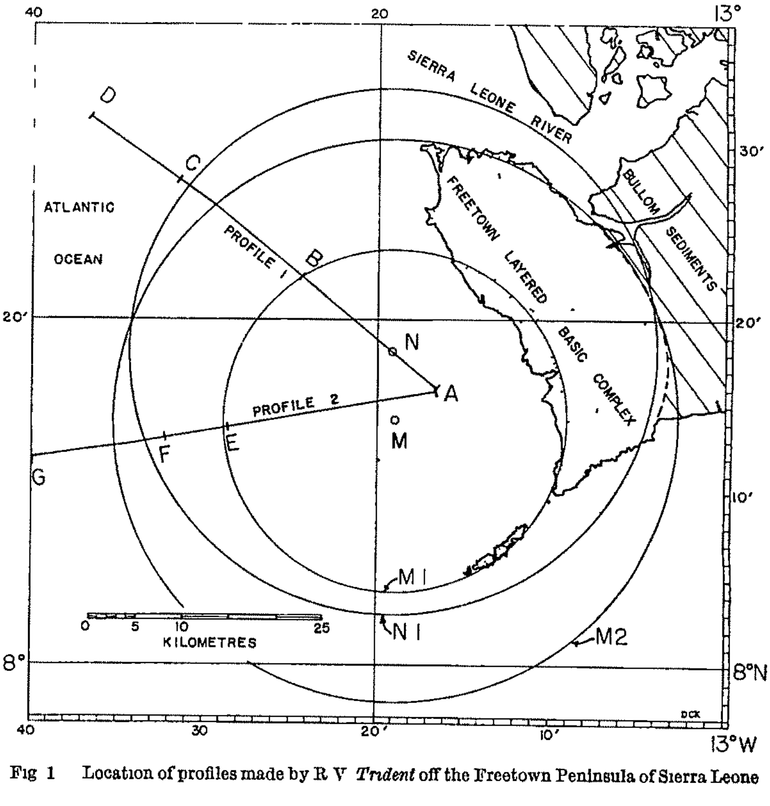

Fig 1 Location of profiles made by R V *Trident* off the Freetown Peninsula of Sierra Leone

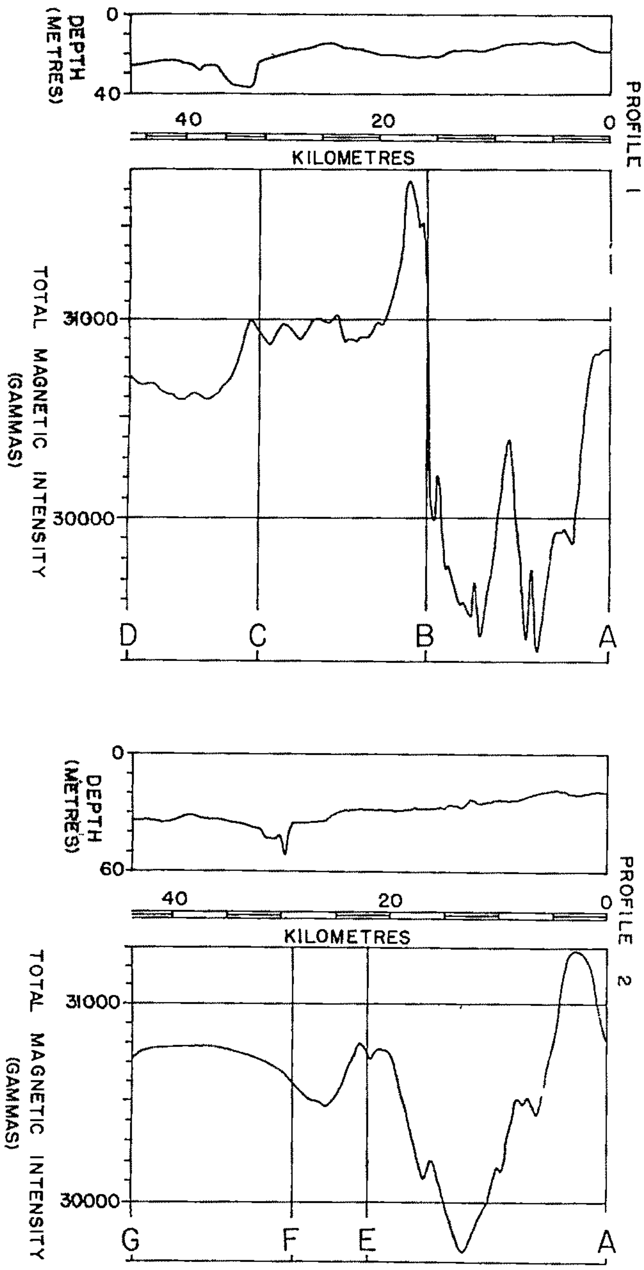

Fig. 2 Echo soundings and magnetometer profiles The vertical exaggeration of the sounding profiles is roughly 333 times The magnetic profiles consist both of the local magnetic anomalies due to nearby rock and of the regional magnetic field due to the Earth's core

magnetic body of rock lies unexposed and central below point *M*

The geometry of the central magnetic body to the layered basic complex of the Peninsula must be one of the following (1) the magnetic rock overlies the basic layers which are truly basal, (2) the magnetic rock is sandwiched between basic layers above and below, (3) the magnetic rock underlies the basic layers, (4) the outcropping basic layers interfinger at depth with the magnetic rock. The magnetic interpretation favours cases one or two because of the apparent 4-km limitation to the base of the body

The lack of correspondence between points *M* and *N* and circles *M*1 and *N*1 suggests that the body is asymmetrical with the southern basal contact rather steeper than the northern basal contact although the body is still relatively saucer-shaped

Identification of meteorite crates by shatter cones[4] and by coesite[5] recently has shown that these are widespread features All circular, enigmatic geological features must now be examined in light of this new evidence and such as the Freetown layered basic complex

As an alternative to Wells's strictly igneous intrusion, I therefore propose that the Freetown basic complex is meteoric in origin, in regard to the location and/or the parent rock If the complex is assumed to be 30 km in radius and cone-shaped with an average dip of 25°, then the apex of the cone is 14 km below sea-level, almost half of the expected crustal thickness The body is so large that the meteorite must have been exceedingly large The asymmetry of the rock body with its more steeply dipping southern wall indicates that the supposed asteroid was moving in a north–south line. A sequence of events is envisaged much like that described by Dietz[6-8] for the Vredefort dome and the Sudbury nickel deposit The forces involved in this impact would be very large and probably disturbed the Earth's crust clear to the mantle Two alternatives exist as to the origin of the basic rock itself under this hypothesis

(1) The crust was fractured and a portion of the mantle was melted The basic rock then intruded the crust and was extruded into the crater as a molten pool which afterwards differentiated and solidified in the manner described by Wells The feature would be funnel-shaped

(2) The basic rock is the asteroid itself which fused on impact The asteroid would have been roughly 9 km in radius and 'stony' in character The mass lay in its crater and slowly differentiated, giving a saucer-shaped body

The latter alternative appears to be of low probability on the basis of the composition of meteorites[9] and on the probable dynamics of meteoritic impact of this size[6] The former alternative is therefore preferred Tests can be made to confirm this hypothesis

KINETICS OF GRAPHITIZATION OF A PETROLEUM COKE

By Dr. D. B. FISCHBACH

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California

GRAPHITE has a hexagonal crystal structure with an ordered *ABABAB* basal plane stacking sequence and a unit cell height, *c*, of 6 708 Å. Pregraphitic synthetic carbons have a similar structure, except that the stacking sequence is randomly disordered (turbostratic structure) with *c* values of 6 85–6 90 Å When such turbostratic carbons are heated to high temperatures graphitization occurs, the layer-stacking evolving toward the ordered sequence of graphite with a consequent decrease in c. Crystallite growth in both the basal plane and c-axis directions also occurs.

The process by which graphitization occurs is complex and is not well understood despite its fundamental importance to the science and technology of carbon and graphite. Information on the kinetics of the process should be very helpful in determining the detailed mechanism. However, until recently, there has been a notable lack of information on the subject. Kinetic studies by Fair and Collins[1] on a conventional composite pitch-coke carbon, and by Mazza, Marchand and Pacault[2] on a coked pitch indicated that the rate of graphitization decreased rapidly with increasing heat treatment time and the degree of graphitization appeared to approach a limiting value at any given heat treatment temperature which increased with heat treatment temperature. However, in general, a zero rate of change was not attained in the total treatment times used, and Mizushima[3] found that the electrical and thermal conductivity changed approximately linearly with the logarithm of treatment time. A recent investigation of pyrolytic carbons[4] has shown that in these materials graphitization occurs by a sequence of two simple first-order rate stages. These results suggested that a further investigation of the kinetic behaviour of conventional carbons would be worth while.

The material chosen for investigation was a petroleum coke which had been baked approximately 15 min at 2,000° C. It had a turbostatic structure with a unit cell height, c, ~ 6.86 Å and a crystallite diameter, L_a, of ~150 Å. Additional information on this coke has been published elsewhere[5]. The progress of the graphitization was followed by X-ray diffraction measurements at room temperature as a function of isothermal heat treatment time. The c value was determined from the position of the (004) diffraction peak using the Debye–Scherrer technique with copper $K\alpha$-radiation. Powder samples were treated in graphite crucibles in a graphite tube resistance furnace at 2,300, 2,500 and 2,700° C in helium at one atmosphere.

The results are shown in Fig. 1 (solid lines) along with curves for a pyrolytic carbon treated at 2,500 and 2,700° C (broken lines). There is a qualitative similarity between the results for the two materials. However, it is evident that the initial rate of graphitization of the coke is much faster than that of the pyrolytic carbon. Furthermore, the kinetic behaviour of the coke cannot conveniently be described by a simple sequence of resolvable first-order stages. The kinetics of the coke can be represented instead by a superposition of many first-order processes with a broad distribution of rate constants. The distribution is so broad that at any one temperature only a portion of the total graphitization process is observed in the time range utilized here. This makes it difficult to determine even an average or effective rate constant at each temperature.

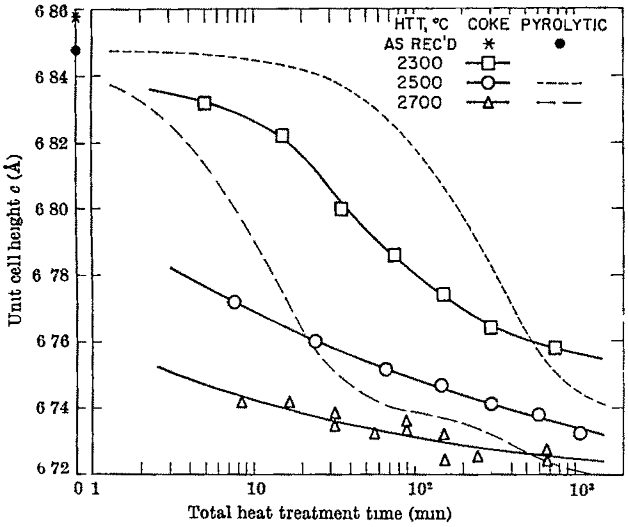

Fig. 1. The unit cell height, c, as a function of heat treatment time at various heat treatment temperatures (HTT) for a petroleum coke (solid lines) and a pyrolytic carbon (broken lines)

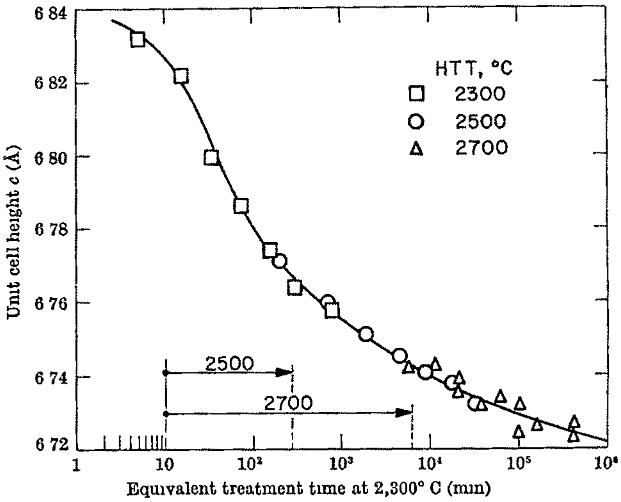

Fig. 2. Composite curve for petroleum coke obtained by shifting the 2,500 and 2,700° C curves to join smoothly with the 2,300° C curve from Fig. 1. The arrows indicate the amount the higher temperature curves were translated along the abscissa

An approach which is commonly used in the analysis of relaxation phenomena is useful here. An effective activation energy can be computed from the amount a kinetic curve corresponding to temperature T_1 must be translated along the time axis to superimpose smoothly on a portion of the curve corresponding to another temperature T_2. It was found that the curves in Fig. 1 could be superimposed in this manner. Fig. 2 shows the composite curve obtained, referred to a temperature of 2,300° C. The arrows show the amount that the 2,500 and 2,700° C curves were displaced. This composite curve may be interpreted as representing the behaviour that would have been observed at 2,300° C if treatment times could have been extended to ~ 10^6 min (about 2 years). This suggests that there is in fact no temperature dependent limit to the degree of graphitization which can be realized at a given heat treatment temperature if the treatment time is long enough.

The value of the effective activation energy obtained from the foregoing analysis is ~ 250 kcal/mole, in excellent agreement with the ~ 260 kcal/mole value observed for pyrolytic carbons. These values are nearly identical to the theoretical value for vacancy diffusion calculated by Dienes[6], as corrected by Kanter[7] (263 kcal/mole), but this agreement is probably fortuitous. On the assumption that graphitization is governed by a broad distribution of activation energies, Mizushima[3] found apparent energy values which increased from ~ 100 kcal/mole at 1,400° C to ~ 200 kcal/mole at 2,200° C, and Fair and Collins[1] deduced somewhat higher values as a function of the degree of graphitization. On the other hand, energy values of 170 kcal/mole for the heat of sublimation[8], 163 kcal/mole for self-diffusion[7] and 90 kcal/mole for crystallite growth[9] have been reported. Evidently, further work is required to establish the nature of the thermally activated processes in carbon and graphite.

The results of the work recorded here indicate that it may be more appropriate to analyse the graphitization process in terms of a distribution of pre-exponential ('frequency') factors than in terms of a distribution of activation energies. The identity of the observed activation energies for pyrolytic carbons and for coke indicates that the thermally activated process is the same for both types of carbon and the activation energy is constant, at least over the range 2,300°–3,000° C. The broad distribution of rate constants in the coke and the different rates in different pyrolytic carbons[4] must then result from large differences in the pre-exponential factor in the rate equation While it is premature to explore this possibility in any detail, such a situation could arise if different numbers of thermally activated steps (for example, diffusion jumps) are required to produce the observed property change in different microscopic environments in the carbons Such differences are presumably associated with differences in the detailed microstructure of the graphitizing carbons

In summary, the graphitization kinetics of a petroleum coke at temperatures in the range 2,300°–2,700° C can be represented by a superposition of first-order rate processes with a broad distribution of rate constants There does not appear to be any temperature-dependent limit to the degree of graphitization attainable at a given heat treatment temperature An effective activation energy of $\sim$ 250 kcal/mole was found, in excellent agreement with the value observed for pyrolytic carbons This indicates that the graphitization process is the same in the two types of carbon and the activation energy is constant The different kinetic behaviour of different carbons is attributed to a broad range of pre-exponential factors which is probably related to the detailed microstructure of the material

MEASUREMENT OF LIQUID SCINTILLATION COUNTING EFFICIENCIES

By HORACE E. DOBBS

U K Atomic Energy Research Establishment, Wantage, Berkshire

LIQUID scintillation techniques for measuring weak β-emitting isotopes are widely used The dissolution or suspension of the substances to be counted in the liquid phosphor often result in reduction of counting efficiency. Such substances, known as quenching agents, can be divided into two broad categories Colourless substances that lower the efficiency of the energy-transfer processes prior to photon emission by the phosphor are known as primary quenching agents Coloured substances that absorb the photons produced by the phosphor are known as secondary quenching agents Some substances exhibit both primary and secondary quenching properties

As most substances exhibit some degree of quenching it is necessary to determine the efficiency of the phosphor solution counted if quantitative radioactivity measurements are required Several methods of achieving this have been described

The most widely used method, known as the internal standard method, is to add a known weight, or volume, of a non-quenching substance of known counting rate[1–4] This method is subject to the personal error of measuring the aliquot of standard The sample is no longer in its original form after 'spiking', and recounting of the original specimen is therefore precluded

A method that overcomes these difficulties, described by Baillie[5] and expanded by Bush[6], utilizes the change in pulse height distribution brought about by the addition of quenching agents, and involves measuring the count rates in two different channels The disadvantage of this method is that when the amount of activity present is small, the time required for the counts to reach a level of sufficient statistical accuracy may be considerable

A method described by Higashimura *et al* [7] utilizes an external γ-source This method relies on the production of electrons within the liquid phosphor by Compton interactions It is therefore subject to the selection of a suitable γ-source and is open to error due to changes in electron density of the counting sample

A method advocated by Peng involves measuring the count rate at different quencher concentrations and extrapolating to zero concentration[8–10] This requires a number of samples to be counted and is valid only if the quenching is a simple function of the sample concentration

If the concentration and composition of the quenching agent are accurately known, the counting efficiency can be determined by reference to prepared quenching curves[11]

Several authors[12–14] have used the extinction coefficient of the solution at 400 mμ (near the optimum sensitivity of the photocathode) to measure the degree of quenching from coloured solutions This method has limited application, and is unsuitable when primary quenching agents are present

A method is described here which has the advantages of the internal standard method, but eliminates the two disadvantages of the method—in that the sample is in its original form after the measurement, and the personal error is eliminated as the amount of activity added for each determination does not vary In this method, a glass rod carrying a fused coating of a suitable long-lived isotope is inserted into the liquid scintillator, and the resulting rise in counting rate is used to measure the counting efficiency of the solution

An 'efficiency stick' was constructed from a piece of glass rod mounted with 'Araldite' into a phial cap (Fig 1) The end of the glass rod was heated to dull red heat and immediately rolled in carbon-14 labelled barium carbonate powder (specific activity 80 μc /mg), located in a channel in a carbon block The glass rod was afterwards reheated to a dull red colour for a short period to allow the barium carbonate to fuse into the glass When cool the

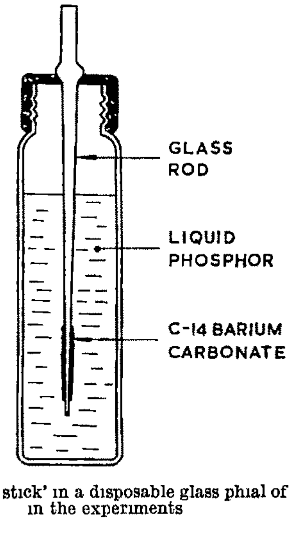

Fig 1. The 'efficiency stick' in a disposable glass phial of the type used in the experiments

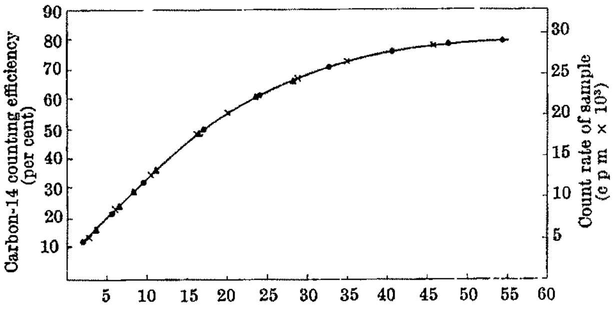

Fig 2 A calibration curve showing the variation of count rate of the stick with the counting efficiency for carbon-14 in a liquid phosphor ×, Primary quenching agent (quinoline) in standard toluene phosphor, ●, secondary quenching agent (scarlet *R*) in standard toluene phosphor, ▲, secondary quenching agent in liquid scintillator composed of toluene, methyl alcohol, 2-phenylethylamine, naphthalene, POPOP and PPO

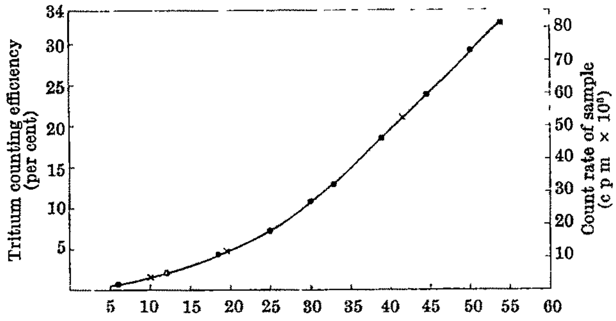

Fig 3 A calibration curve, indicating the variation of the count rate of the same stick, for different tritium counting efficiencies in a toluene-based phosphor ×, Primary quenching agent (quinoline), ●, secondary quenching agent (scarlet *R*)

stick was washed in toluene and wiped vigorously with a paper tissue to remove any loosely bound activity

Experiments were conducted in a co-incidence system[15] in which 9 0 ml counting samples were placed in disposable glass phials The discriminators were set such that all pulses greater than 5 V were recorded A suitable working voltage for the photomultipliers was selected by plotting the counting rate of the phosphors against high-voltage supply both with, and without, the efficiency stick It was necessary to leave the stick in the solution for several minutes before counting to allow the count rate to reach a constant level

The calibration curve for the efficiency stick was prepared as follows 0 1 ml of carbon-14 labelled toluene of known count rate was added to 9 0 ml of liquid phosphor The composition of the phosphor was 5 g PPO (2,5-diphenyl oxazole) and 0 05 g POPOP (1,4-*bis*(2-[5-phenyloxazole]) benzene) per litre of toluene Successive quantities of a primary quenching agent (quinoline) were added, and the count rate measured before and after insertion of the stick for each addition The count rate of the solution (which is directly proportional to the counting efficiency) was plotted against the additional count rate produced by inserting the stick The results are shown in Fig 2

The procedure was repeated with a secondary quenching agent (a solution of scarlet *R* in toluene) in phosphor of the same composition A liquid phosphor of different composition, composed of equal parts of toluene, methyl alcohol, and 2-phenylethylamine, containing 5 g/l of PPO, 0 05 g/l POPOP, and 100 g/l naphthalene[16] was also investigated using scarlet *R* as a quenching agent The results are shown in Fig 2

It can be seen from Fig 2 that the results from all three experiments fall on the same curve The additional counts produced by inserting the efficiency stick can therefore be used to measure the counting efficiency of a liquid scintillator containing an unknown quantity of a primary and/or secondary quenching agent

The same efficiency stick has been calibrated for measuring the efficiency of a phosphor (toluene containing 5 g/l PPO and 0 05 g/l POPOP) containing tritium activity The results (Fig 3) indicate that both primary and secondary quenching agents give points that lie on one curve

The stick is stored in liquid scintillator solution and has shown no detectable loss of activity over a period of 3 months It has frequently been used without ill effect to measure the efficiency of a phosphor containing a strong base[16] used to absorb carbon dioxide produced by the combustion of carbon-14 labelled compounds

The use of the method described has the advantage that results can easily be cross-checked by recounting the solution after the introduction of another efficiency stick containing more, or less, activity.

Caution should obviously be exercised when using the stick to measure the efficiency of acid solutions, as there is a possibility that some of the activity on the stick would be liberated as carbon dioxide The method does depend on the day-to-day stability of the counting equipment This can easily be checked by counting a sealed phial containing a standard solution, or by counting the stick in unquenched phosphor of known efficiency before use

A NEW CONFORMATION OF METHACRYLIC ACID RADICALS IN SOLID-STATE POLYMERIZATION

By PROF. C. H. BAMFORD, DR. G. C EASTMOND and Y SAKAI
Department of Inorganic, Physical and Industrial Chemistry, University of Liverpool

WE have previously shown[1,2] that the solid-state polymerization of methacrylic acid initiated by ultra-violet radiation proceeds through radical intermediates and that during the reaction radicals become trapped in the matrix Further, it was shown that radical formation appears to have an unusually large temperature coefficient for a photochemical process In order to obtain more information on this point we have investigated the polymerization at temperatures below 0° C in more detail, using electron spin resonance spectroscopy to examine the radicals The results described here showed an unexpected variation of the radical concentration with temperature of irradiation and also revealed a new electron spin resonance spectrum of methacrylate-type radicals, containing thirteen lines instead of the usual nine

Methacrylic acid was purified as described previously[2] and the polycrystalline specimens, formed by freezing at 77° K in vitreosil electron spin resonance sample tubes, were irradiated for various periods by light from a high-pressure mercury arc at predetermined temperatures in the range +10 to −40° C These temperatures were maintained by passing cold nitrogen around the sample tubes[2] A Varian *V* 4500 spectrometer was used for recording the electron spin resonance spectra with the specimens maintained at 77° K

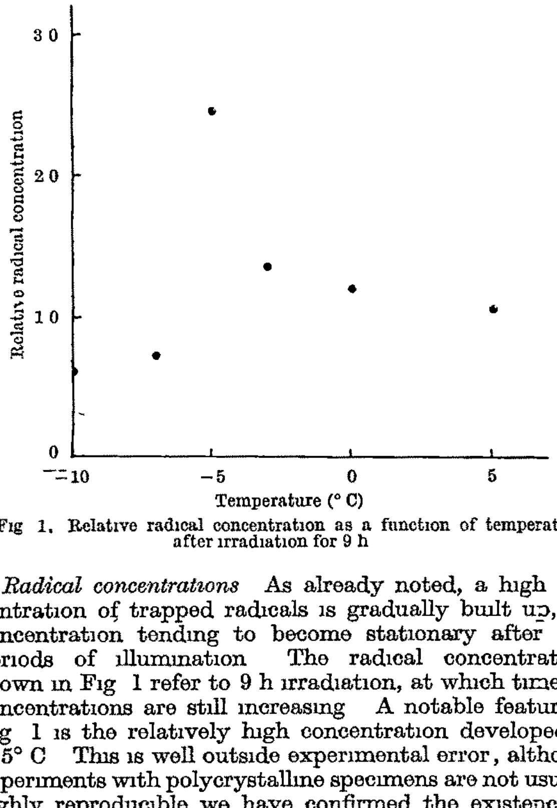

Fig 1. Relative radical concentration as a function of temperature after irradiation for 9 h

Radical concentrations As already noted, a high concentration of trapped radicals is gradually built up, the concentration tending to become stationary after long periods of illumination The radical concentrations shown in Fig 1 refer to 9 h irradiation, at which time the concentrations are still increasing A notable feature of Fig 1 is the relatively high concentration developed at −5° C This is well outside experimental error, although experiments with polycrystalline specimens are not usually highly reproducible we have confirmed the existence of this effect many times Initiation is probably controlled by the freedom of movement of the monomer molecul[illegible] in the lattice, radical formation may require int[illegible] between an excited and a normal molecule [illegible] event, it must be accompanied by conf[illegible] At −5° C there may be a trans[illegible] that at this temperature the [illegible] enhanced, together with [illegible]

Table 1

No	Temperature of irradiation (° C)	Time of irradiation (h)	$\frac{x}{y}$	Time of annealing (min)	$\frac{x}{y}$ after annealing
1	−30	9	0 35		
2	−20	9	0 25		
3	−5	3	0 11		
4	−5	18	0 04		
5	−5	40	0		
6	−10	3	0 28		
7	−10	6	0 20	20	0 13
8	−10	40	0 05		
9	−10	6	0 11	40	0 033
10	−10	6	0 11	60	0 026

comparison with Fig 2 The ratio x/y is used as a measure of the importance of the splitting It will be seen that the splitting becomes less noticeable as the period of irradiation at a given temperature is increased (Exps 3–5, 6–8)

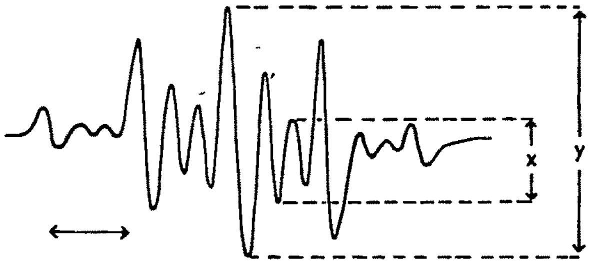

Fig 2 Electron spin resonance spectrum of radicals formed in crystalline methacrylic acid at −30° C Scale=20 gauss

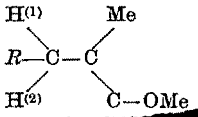
Annealing experiments were also carried out in which specimens irradiated at lower temperatures were maintained at 0° C The electron spin resonance spectra obtained from such specimens show a reversion to the conventional 9-line spectrum (Exps 7, 9, 10)

We believe that the observations can be discussed most profitably in terms of radical conformation, and indicate that below −5° C radicals are formed photochemically and have a conformation different from that of the familiar methacrylate radical (obtained, for example, by trapping during the polymerization of methyl methacrylate at room temperatures and above) Symons[3,4] has recently discussed the evidence that the 9-line spectrum of this radical arises from a single radical species I, and an extension of his arguments is capable of accounting for our 13-line spectrum



(I)

[illegible] tation [illegible] oms [illegible]

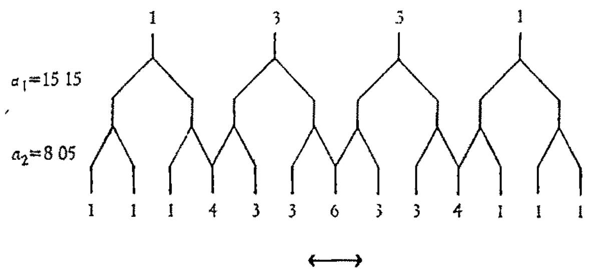


Fig 3 Origin of 13-line spectrum and relative intensities of lines Scale = 10 gauss

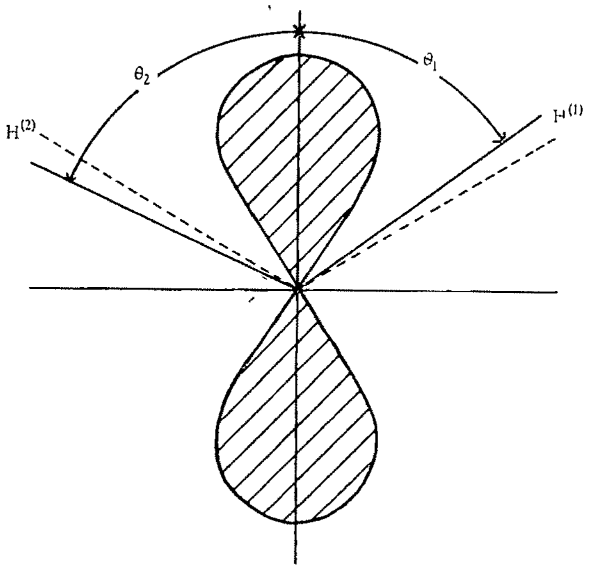

Fig 4 Positions of methylene hydrogen atoms in methacrylic acid radical, looking along C—C bond ---, Symmetrical conformation, $\theta_1 = \theta_2 = 60°$, ——, new conformation, $\theta_1 = 55°$, $\theta_2 = 65°$

Experimentally we find that $\Delta = 7\ 1$ gauss, so that $a_1 = 15\ 15$, $a_2 = 8\ 05$ gauss The manner in which the 13-line spectrum arises with these parameters is shown in Fig 3, from which it appears that the relative intensities are 1, 1, 1, 4, 3, 3, 6, 3, 3, 4, 1, 1, 1

If we assume that the non-equivalence of the methylene hydrogen atoms arises from displacements from the symmetrical conformation $\theta_1 = \theta_2 = 60°$ (Fig 4) we may calculate θ_1, θ_2 by the use of Symons's relation[4]

$$a = 46 \cos^2 \theta \tag{2}$$

It turns out that $\theta_1 = 55°$, $\theta_2 = 65°$ There is, therefore, no distortion of the $H^{(1)}CH^{(2)}$ angle, but the whole group is rotated about the C—C bond through 5° (Fig 4)

We believe that, during the solid-state polymerization below −5° C, geometrical constraints within the crystal force the radicals (or some of them) to adopt this conformation, which is maintained at these temperatures on account of the reduced mobility below the 'transition point'

On warming to 0° C, however, relaxation occurs and the usual conformations appear If irradiation is prolonged, extensive disorganization of the crystals is caused by the polymerization, with resultant weakening of the constraints responsible for the new conformation Over most of the narrow range of irradiation temperatures −5° to −30° C the spectrum corresponds to a mixture of the conventional and new conformations, with the proportion of the latter increasing as the temperature falls After irradiation at −30° C the observed relative intensities are not very different from those predicted (1, 1, 1, 4, 3, 3, 6, 3, 3, 4, 1, 1, 1) so that under these conditions substantially all the radicals have the new conformation So far as we are aware this is the most definite evidence that a methacrylic (or methacrylate) radical spectrum can be related to a single conformation without the need for special assumptions

The conformational hypothesis is not the only one capable of accounting for the difference between a_1 and a_2 Even in the symmetrical conformation the methylene hydrogen atoms may not be equivalent since their environments differ[4] However, since methacrylic acid and methyl methacrylate radicals normally give similar electron spin resonance spectra we do not think this alternative is very likely

The results described do not seem capable of interpretation in terms of the formation of a chemically different radical species at the lower temperatures

We thank Dr L H Sutcliffe for discussion and Dr A Bullock for help in recording the electron spin resonance spectra

[illegible] TINUOUS DETERMINATION OF ANÆSTHETIC [illegible] TENTIAL *IN VIVO*

[illegible] NS

[illegible] Oxford

[illegible] compartments as fatty tissue are [illegible] be considered divided into equilibrium with the compartment entered. A number of physical properties of materials vary quantitatively with the concentration of an introduced volatile substance, but it is thought that the easiest quantity to measure with a small probe is the rate of permeation of the substance itself through a thin plastic membrane.

The permeation of plastic membranes by organic vapours has been investigated quantitatively and theoretically[6,7]. For polymers which are either in their rubber-like state or, for other reasons, do not have high viscosities, the process is describable in terms of solution at one surface, diffusion through the material according to Fick's law, and evaporation from the other surface.

For simple gases and substances chemically different from the membrane material, the rate of permeation is strictly proportional to the difference in chemical potentials across the membrane. Organic vapours permeate many times faster than simple gases, the highest figures being given by substances chemically similar to the membrane material and showing the greatest tendency to dissolve it. The rate of permeation of these solvent-like substances increases disproportionately fast with rising chemical potential, probably owing to swelling of the polymer by the agent. At the low chemical potentials used in anæsthesia (in the range 0.02–0.05) the curvature is not great and may be accurately described by an equation of the form

$$R = \frac{PA\mu p_s e^{\alpha\mu}}{d}$$

where R = rate of transfer (ml at S.T.P./sec) across a membrane of area A (cm²) and thickness d (cm) exposed on one side to an anæsthetic at chemical potential μ, the concentration on the other side being negligible. P is the permeability coefficient (ml at S.T.P. cm/cm²/sec/mm mercury) at $\mu \to 0$, p_s is the saturation partial pressure of the anæsthetic (mm mercury) and α is a constant which must be determined for each combination of anæsthetic and membrane material.

The permeability coefficient P typically shows a large increase with temperature defined by the equation

$$P = P_0 e^{-E_p/RT}$$

where P_0 is the value of P at infinite temperature, T is the absolute temperature, R the gas constant, and E_p the activation energy of permeation, which proves close to the activation energy of solution of the membrane material. Changes in P of 5 per cent per deg. C are not uncommon when E_p is high and may need correction even within the narrow range of temperatures encountered in normal anæsthesia.

The rate of permeation through the test membrane can be determined conveniently by measuring concentration in a constant flow of gas passing over its free surface. In tissue with poor circulation it would be necessary to keep the rate of removal of anæsthetic to a minimum. In order to estimate the permissible withdrawal, assume the probe to be in tissue with a long half-equilibration time of 50 min, let the equilibrium anæsthetic concentration be 1 mg/ml, and assume withdrawal at equilibrium of 10 ng/min. This would give a detector concentration of 10^{-9} g/ml at 10 ml/min gas flow. If the probe is in equilibrium with 0.1 ml of tissue, then at half saturation of this compartment anæsthetic will be entering at an instantaneous rate of 0.7 μg/min. The rate of withdrawal will depend on the instantaneous chemical potential and at this moment would be 5 ng/min. The value under observation would be lowered less than 1 per cent and this would be true at all stages of equilibration. For measurements in tissue with good circulation and in blood and cerebrospinal fluid the permissible withdrawal would be several orders of magnitude higher.

The argon gas chromatograph detector[10] will operate at 10^{-12} g/ml of organic vapour, and measurements at 10^{-10} g/ml are within the quantitative range. It can now be constructed with a volume of 0.3 ml or less. Unfortunately, many of the heavily halogenated compounds used in anæsthesia will not produce a positive response in the argon detector, though a modification of this to detect them has been suggested[11]. They can, however, be measured at about the same level of sensitivity by the electron capture detector[12], and it might be possible to design a detector cell which could be used on either principle, the essential practical difference being the voltage applied to the electrodes and the sensitivity of the arrangements for current measurement.

Possible interfering substances which may also cross the membrane include oxygen, nitrogen, carbon dioxide and water vapour. Lovelock[13] has shown that the sensitivity of the argon detector is reduced only at concentrations higher than 3×10^{-4} (by volume) of water vapour and 1×10^{-4} of carbon dioxide. The saturated vapour pressure of water at 37° C is 47 mm, the physiological partial pressure of carbon dioxide is about 38 mm and the effective partial pressure of a typical anæsthetic is only 4 mm. Taking permeabilities for the interferants from Table 1, assuming a permeability to anæsthetic equal to that for water and a hypothetical molecular weight of 100, then with a membrane thin or large enough to give the limiting concentration for water, carbon dioxide will be only at 1/10 of its interference-level and the detector can receive 1×10^{-7} g/ml of anæsthetic, which is 10^3 times higher than the lowest quantitative range. Using a polythene membrane 0.001 in. thick and a detector gas flow of 10 ml/min, a probe area of about 3 cm² would be needed to achieve this concentration. With a detector sensitivity of 10^{-9} g/ml for full-scale deflexion this could be reduced to 0.03 cm² and very small probes should be possible.

Table 1. PERMEABILITY COEFFICIENTS AT 30° C FOR LOW-DENSITY POLYTHENE
(ml at S.T.P. cm/cm²/sec/mm mercury)

Permeant	$P \times 10^{11}$	Ref
Oxygen	5.5	8
Nitrogen	1.9	8
Carbon dioxide	35	8
Water (liquid or vapour)	100	9
Methyl bromide (μ=0.12)	99	7
n-Hexane (μ=0.23)	180	7

The ideal membrane should have the highest possible permeability to organic vapours relative to water and should therefore be non-polar. Low-density polythene was used in an experimental probe, but it is possible that polyvinylidene chloride (Saran) or PTFE might have even more favourable properties.

A simple probe was constructed by fastening polythene film 0.001 in. thick over the end of two concentric glass

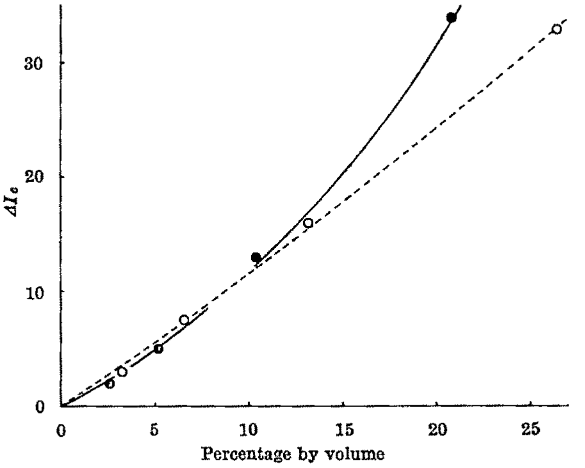

Fig. 1. Arbitrary units of increase in detector cell current plotted against percentage by volume of anæsthetic in air (calculated at S.T.P.). ●, Ether; ○, ethyl chloride

tubes, the inner fractionally shorter than the outer The free membrane area was 0 55 cm^2 Argon was passed into the outer tube at 10 ml /min and led from the inner through glass tubing and an empty column at 50° C to the detector of a Pye argon chromatograph, type 12001 (W G Pye and Co , Ltd , Cambridge), used at 2,000 volts and maximum sensitivity This method of connexion entailed a very large dead volume, but was necessary for reasons of safety as the instrument has a strontium-90 rather than a tritium source

The probe was immersed in water at room temperature in a small flask through which bubbled a stream of air at 2 l /min The air stream came from an anæsthetic vaporizer of the type described by Burn, Epstein and Goodford[14] and passed through a large mixing chamber (5 l) When a baseline was established, known concentrations of anæsthetic were added to the stream The increase in cell current was determined at equilibrium after each stepwise increase in concentration Only anæsthetics suitable for the argon detector could be used Fig 1 shows scale units of current rise plotted against the composition of the known mixtures It was confirmed that replacement of the air stream by oxygen with 5 per cent carbon dioxide had no detectable effect on the reading The points for 6 6 and 13 per cent by volume of ethyl chloride were repeated with citrated human blood in place of water, and it was confirmed that readings agreed with those in water to an accuracy within the noise-level of the recording instrument (average one scale unit) Foaming of the blood was checked by use of Midland Silicones 'Anti-foam *A*'

It is concluded that continuous measurement of anæsthetic potential in blood or cerebrospinal fluid by a membrane probe is a practicable proposition and that it should be possible to develop the instrument to a sensitivity high enough to make measurements in tissue with poor circulation

ADDITIVE EFFECT OF SUB-THRESHOLD CONCENTRATIONS OF SOME ORGANIC COMPOUNDS ASSOCIATED WITH FOOD AROMAS

By D. G GUADAGNI, RON G. BUTTERY, S. OKANO and H. K BURR

Western Regional Research Laboratory, U S Department of Agriculture,
Albany 10, California

THE marked advance of gas chromatographic techniques in recent years has revealed the presence of large numbers of organic volatile compounds in fruits and vegetables[1]. Since many of these volatiles are found in extremely small quantities, the organoleptic significance of mixtures of trace amounts becomes of interest

Taste and olfactory thresholds of some organic compounds associated with food flavours have been reported[2,3], and the possible additivity of sub-threshold concentrations of mixtures of organic compounds have recently appeared in the literature[4,5] The purpose of these experiments was to determine which of the following possibilities is characteristic of the odour properties of mixtures (1) The mixtures exhibit an independent property, in which case no odour would be perceived unless at least one compound in the mixture was at or above its threshold (2) They counteract one another, in which case a mixture of the threshold concentrations of two compounds would no longer give an odour sensation (3) They exhibit an additive effect, in which case half the threshold concentration of each of two compounds mixed together would give a perceptible odour (4) They exhibit a synergistic effect or enhancement in excess of addition

Purity and thresholds of individual compounds and mixtures of compounds were determined by methods that will be published elsewhere[6] Very briefly, compounds were purified by gas liquid chromatographic separation and thresholds were determined as follows The panel of judges consisted of 20–25 persons who consistently demonstrated sensitivity and reproducibility in perception of odour There were 16 males and 9 females selected from a group of more than 60 laboratory employees Odour measurements were made in a room maintained at 22° C and equipped with individual booths which were constantly flushed with fresh air which had been scrubbed through activated charcoal filters The rate of air movement was such that the room was under slight positive pressure to prevent entrance of odours through booth openings and doors Pure compounds were dissolved in triple-distilled odour-free water at 22° C just before the panel convened Thresholds were determined by evaluating two or more series of 3–6 concentrations each Each concentration was paired with samples of triple distilled odour-free water, and the entire panel was asked to check the samples that contained the odorous material Position of the water sample was randomized in each pair, and order of presentation of the different concentrations was also randomized. The solutions (4 fl oz) were presented in boiled odour-free 8-oz 'Teflon' bottles Sufficient time (2–3 min) was allowed for equilibrium to be established between solution and vapour The judges gently squeezed the bottles to force the vapour above the solution directly into the nasal cavity The percentage of correct responses was plotted against concentration The threshold is arbitrarily defined as the concentration at which a highly significant ($P = 0\ 01$) percentage of the judges detected the aroma

The threshold of a mixture was usually determined by mixing the compounds in a 1 1 ratio according to their individual thresholds The mixtures were judged in concentrations above and below their expected thresholds, usually at levels of 50–300 per cent of the expected threshold. assuming condition 3 (additive effect) to be operative With a mixture of 3 compounds, for example, each compound was present at 16 66 per cent of its threshold for the low concentration (50 per cent) and at 100 per cent of its threshold for the high concentration (300 per cent) The theoretical threshold of a mixture was calculated from the individual threshold values of the compounds of the mixture, assuming an additive effect The percentage of the theoretical threshold actually found in the mixture was then calculated, and the percentage or fraction of this value contributed by each compound was also calculated Thresholds of the purified individual compounds were verified both before and after threshold determinations of the various mixtures

For the initial experiment on effect of sub-threshold concentrations, 3-methylbutanal and heptanal were combined in several different proportions, and the thresholds of the mixtures determined Even though the range of concentration ratios of the pure compounds varied from 0 1 1 to 4 95 1 the thresholds of the various mixtures were always near 100 per cent of the theoretical level (Table 1) This experiment demonstrates an additive effect for sub-threshold concentrations of these two compounds over a wide range of combinations

Table 1 ADDITIVEE FFECT OF THE ODOURS FROM *n*-HEPTANAL AND 3-METHYLBUTANAL MIXED IN VARIOUS RATIOS

Ratio of *n*-heptanal to 3-methylbutanal*	Ratio of threshold concentrations of *n*-heptanal to 3-methylbutanal	Threshold of mixture as a percentage of theoretical threshold
2 1	0 10 1	102
4 1	0 20 1	101
9 1	0 45 1	100
19 1	0 95 1	87
29 1	1 45 1	103
39 1	1 95 1	99
99 1	4 95 1	107

* Thresholds of *n*-heptanal and 3-methylbutanal were 3 0 and 0 15 parts per billion parts of water (p p b) respectively

To investigate other mixtures of interest, various compounds were combined in a 1 1 ratio of their respective thresholds, and the thresholds of these mixtures were determined Again, an additive effect was demonstrated (Table 2) The only exception is the mixture of dimethyl sulphide and 3-methylbutanal which gave a threshold of 137 per cent of the theoretical value All other values are close to the theoretically calculated thresholds

Members of a single class of compounds, such as the saturated aldehydes, might be expected to exhibit an additive effect, but members of different classes with different structures would not necessarily be expected to behave in the same way Only a limited number of mixtures containing different structures or classes were tested, and it is not implied that the effect observed would hold for all combinations that could be made However, the mixture of saturated, unsaturated, and branched-chain aldehydes and the mixture of these aldehydes with dimethyl sulphide indicate that a wide range of combinations do give an additive effect Furthermore, the mixture of an alcohol, an acid, a sulphide, an aldehyde and an amine also demonstrated the effect The possibility of chemical interaction is considered negligible because of the extremely low concentrations and short time interval between mixing the chemicals and smelling Therefore, additivity of sub-threshold concentrations appears to be widespread and could be of importance in determining the characteristic flavour of various food products Consider the mixture of 10 saturated aldehydes (Table 2) Each compound in the mixture is present at only about 10 per cent of its threshold concentration, but when combined with the 9 other compounds, odour was perceived In food products, which often contain large numbers of compounds, it is not difficult to imagine the importance of such complicated mixtures, even if each component is present in sub-threshold amount

Table 2 ADDITIVE EFFECT OF ODOUR OF COMPOUNDS IN MIXTURE

	1 . 1 Threshold ratios of	Threshold of mixture as a percentage of theoretical threshold	Average % contributed by each compound
	Saturated Aldehydes		
A	3-Methylbutanal + heptanal	100	50
B	*A* + propanal	102	34

S	*R* + 2-nonenal	109	27
T	*S* + butylamine	100	20

In a recent report, Nawar and Fagerson[7] pointed out the potential significance of sub-threshold amounts of some methyl ketones They concluded that a synergistic effect was obtained by combining the compounds. With the compounds and mixtures used in our experiments, the effect appears to be additive rather than synergistic, subtractive, or independent In any event, the observation that mixtures of sub-threshold amounts of odorous materials are capable of inducing olfactory response is of both practical and theoretical interest

CHEMICAL INDUCTION OF MAMMARY CANCER IN GERM-FREE RATS

By DR. MORRIS POLLARD

Lobund Laboratory, University of Notre Dame, Indiana

NEOPLASMS can be induced in experimental animals by chemical, by physical, and by biological agents[1] Experiments on carcinogenesis have been performed predominantly in conventional animals which carry a microbial flora of great variety and of uncertain significance While viruses have been clearly implicated in the genesis of neoplastic cells[2], they are not necessarily exclusive agents in that effect The role of micro-organisms in chemical carcinogenesis needs clarification, particularly from the point of view of the chemical agents unmasking (activating) latent oncogenic viruses in the host The unmasking of viral leukæmia by X-rays in low-leukæmia mouse strains has been abundantly documented[3], and this may be relevant to a similar effect by chemical agents Virus-like particles have been described in or around cells of spontaneous tumours in man and animals, thereby leading to an interpretation of causal relationship, but this may actually represent a fortuitous encounter with an unrelated viral agent Viruses initiate tumour formation and then may disappear as distinct entities, while their product flourishes[4] This suggests that perpetuation of the oncogenic effect is not necessarily dependent on overt viral activity, once the cell transformation has occurred

If germ-free animals are free of virus, then they should serve to clarify the role of microbial flora in chemical carcinogenesis Several strains of rats and mice have been

Table 1 RESPONSE OF CONVENTIONAL AND GERM-FREE RATS TO ORAL ADMINISTRATION OF 20 MG DMBA

	Conventional			Germ-free		
Rat strain	Number fed	DMBA toxicity	Tumours	Number fed	DMBA toxicity	Tumours

Wistar	12	0/12	0/12	8	3/8	1/5 (111)*
Fischer	9	0/9	0/9	15	15/15	

* Deaths associated with DMBA toxicity/number fed

† Number of animals developing tumours/number fed (average latency period in days)

reared, maintained, and propagated through numerous generations in the germ-free environment, by a method developed in this Laboratory[5]. At term, Wistar rats were transferred *in utero* through a germicidal trap into the germ-free isolator. The baby rats were then removed from the uterus and fed individually a sterile diet by stomach tube until weaning time. The germ-free rat strain, which was started in this way, has now been propagated by natural means through 21 successive generations in the germ-free state. Sprague–Dawley and Fischer rats were similarly transferred *in utero* into the germ-free isolator. They were foster-nursed on germ-free Wistar rats, and thereafter propagated up to the sixth generation by natural means. Some spontaneous breast tumours and occasional thymomas have appeared in Wistar rats[6], whereas none has been observed in germ-free Fischer and Sprague–Dawley rats, which are being propagated here. The incidence of tumours in Wistar rats could not be determined since animals were being removed frequently from the colony for unrelated experiments. Examinations of such germ-free animals in this laboratory for parasites, fungi, bacteria, pleuropneumonia-like organisms and for viruses have thus far been negative[7].

In preliminary experiments several strains of germ-free Swiss–Webster mice and Fischer rats were inoculated subcutaneously with sterile 3-methylcholanthrene (3-MC) in olive oil; and all animals so inoculated developed transplantable fibrosarcomas in the inoculated area. Germ-free and conventional Swiss–Webster mice, inoculated subcutaneously at birth with 3-MC, developed pulmonary adenomas within 8 weeks[8]. All the 3-MC-induced germ-free and conventional tumours, although indistinguishable histologically, appeared in the germ-free animals in more uniform fashion. Examinations of spontaneous and of 3-MC-induced tumours from germ-free animals, by standard virological procedures and by electron microscopy, have failed to reveal evidence of viral agents.

Huggins *et al.* have described the rapid induction of breast tumours in conventional rats, following a single oral administration of 20 mg 7,12-dimethylbenz(*a*)anthracene (DMBA) in sesame oil[9]. The rat most responsive to this treatment is the Sprague–Dawley female, fed DMBA between 50 and 60 days of age. Examinations of such animals and their tumours for viral agents have not been reported. Susceptibility to breast cancer by this procedure was not altered by foster-nursing new-born Sprague–Dawley rats on mothers of other genetic strains, or *vice versa*, indicating that susceptibility may be related to a genetic trait[10]. Strain differences may thus be due to an inherited variation in their endocrine constitution with varying sensitivity of the mammary gland to the carcinogenic effect of the hydrocarbon.

DMBA was dissolved by heat in sesame oil (20 mg/ml.), sealed in glass ampoules, and sterilized in the autoclave (15 lb./20 min). Female Wistar, Fischer and Sprague–Dawley rats, germ-free and conventional counterparts, were each fed 20 mg DMBA by stomach tube, on a single occasion, at 50–60 days of age. The germ-free animals were thereafter maintained in the germ-free state. When a palpable tumour was detected, the affected animal was removed from the isolator, or from the animal house, to the laboratory for autopsy. The animal was killed by cervical section, tumour and other tissues (lung, liver, spleen, lymph nodes, lachrimal gland) were collected aseptically for determination of viral content, for examination in paraffin- and in epon-embedded sections—the latter for examination by electron microscopy. Thirty-eight Sprague–Dawley rats were fed the DMBA preparation, and 13 (34 per cent) of them died within 30 days (Table 1). The cause of DMBA-associated deaths, in germ-free and in conventional rats, was not determined. The remaining rats (9 germ-free and 18 conventional) were observed for 180 days. Three of 8 germ-free Wistar rats died within 20 days following DMBA feeding, and they showed no evidence of tumours at autopsy. All of 15 germ-free Fischer rats, fed 20 mg DMBA, died in 15 days without showing evidence of tumour formation. All germ-free rats showed the enlarged cæcum which is usually observed in such animals.

The 9 germ-free Sprague–Dawley rats which survived the treatment with DMBA developed breast tumours (one to eight per animal) on average at 82 days. Of 18 conventional Sprague–Dawley counterparts, 16 developed mammary tumours on average at 103 days; the number and distribution of tumorous glands were essentially the same as among the germ-free animals. A mammary tumour was detected in one of 5 germ-free Wistar rats at 111 days following administration of DMBA. Tumours appeared only in the mammary glands, and all were solid, circumscribed adenocarcinomas. Metastatic neoplastic foci were not observed.

The fate of cancerous animals was not determined since each animal was killed and autopsied soon after a tumour was detected. The difference in latent periods, 82 days for germ-free and 103 for conventional, may be significant since palpation of tumours in the former through heavy rubber gloves was not so sensitive as with the latter for which the bare hand was used. Possibly, therefore, the latent period in germ-free rats may be shorter.

Tissue cultures were prepared as cell monolayers in bottles and on coverslips in Leighton tubes from trypsin-dispersed germ-free rat fœtuses. The nutrient fluid contained Mixture 199 with 0.5 per cent lactalbumin hydrolysate and 5 per cent heat-inactivated calf serum. The tissue cultures were inoculated with (*a*) cell-free extracts of tumours or of organ tissues in Mixture 199; (*b*) explants prepared from minced tumour tissue; (*c*) cell suspensions prepared by trypsinization of the minced tumour tissue. Nutrient fluids were changed every 4 days over a period of 60 days. Tissue cultures were examined microscopically at frequent intervals for evidence of cytopathogenic effect. If cytopathogenic effect was observed, the whole culture was frozen and thawed twice, and passaged to fresh tissue cultures. The cells on coverslips were stained by May–Grunwald–Giemsa technique and examined microscopically at intervals after onset of cultivation. Extracts of the tissue cultures were examined for hæmagglutinins with mouse, sheep, guinea pig, and human type O erythrocytes at room temperature and at 4° C. No viral agent has as yet been detected in the tumours or in the tissues of the germ-free rats. Tumour cells, examined by electron microscopy, have not revealed evidence of virus-like particles in or around the cells.

Mammary carcinomas were induced by orally administered DMBA in germ-free Sprague–Dawley rats, in which neither spontaneous tumours nor viral agents have as yet been detected by us. Spontaneous tumours might appear among older germ-free rats of the Sprague–Dawley strain, however, a sufficient number has not yet been accumulated on which to base such information. The findings reported here add affirmation to the concept that there are undoubtedly mutiple initiators of the same cellular alterations which lead to a neoplastic transformation , and that they may be evoked by chemical, physical, or biological agents

BIOSYNTHESIS OF MESSENGER AND RIBOSOMAL RIBONUCLEIC ACIDS IN THE NUCLEOLOCHROMOSOMAL APPARATUS OF ANIMAL CELLS

By G. P GEORGIEV, O. P. SAMARINA, M I. LERMAN, M N. SMIRNOV
and A. N. SEVERTZOV

Institute of Animal Morphology, Institute of Radiation and Physico-Chemical Biology,
Academy of Sciences and Institution of Biological and Medical Chemistry,
Academy of Medical Sciences, Moscow, U.S S R.

DURING recent years we have been investigating the problem of biosynthesis of RNA in the nucleus of mammalian cells The main method used was phenol fractionation of cellular RNA which permits the separation of the rapidly labelled RNA of the cell and isolation of its fractions This article presents some new results concerning the properties of nuclear RNA's and their transport from the nucleus into the cytoplasm. The terminology adopted here for designation of different types of high-molecular weight RNA is as follows. R–RNA–RNA with base composition similar to ribosomal RNA; D–RNA–RNA with DNA-like base composition (it corresponds to messenger RNA)

Present state of phenol method of cellular RNA fractionation The first approach to phenol fractionation of cellular RNA was made independently by Sibatani *et al*[1] and by Georgiev and Mantieva[2] It was shown that a small part of RNA was not deproteinized by phenol at neutral *p*H and that this RNA possessed high specific activity This RNA was shown to be bound in the cell nuclei which survived the treatment with phenol *p*H 6–0 14 M sodium chloride in the cold The nuclei are shown on the boundary of saline and phenol as an intermediate layer ('interphase') The procedure for purification of these 'phenolic nuclei' was described[2]

The RNA of phenolic nuclei was roughly identified as RNA of nucleoli and chromosomes or RNA of 'nucleolochromosomal apparatus' (NC-apparatus) The cytoplasmic RNA and RNA of nuclear sap were extracted under standard conditions After incubation of cells with labelled precursors for 0 5–1 h nearly 90 per cent of total radioactivity incorporated into high-molecular weight RNA of the cell was recovered in NC–RNA Therefore, NC–RNA appears to be a 'rapidly labelled' RNA of the animal cell[1–3]

Further progress was achieved when the procedure for isolation of RNA from phenolic nuclei was carried out[3] If phenolic nuclei are treated by phenol *p*H 6–0 14 M sodium chloride at 65° C, all their RNA is liberated It was demonstrated that NC–RNA contained both ribosomal RNA identified by typical profile in analytical ultracentrifuge and RNA with different base composition[4] We succeeded in separating these RNA's and in obtaining for the first time from animal tissues RNA fractions similar in base composition to DNA (D–RNA, messenger RNA) and also RNA fraction similar to ribosomal RNA (R–RNA)[3] Sibatani *et al*[4] have proposed another procedure for isolation of D–RNA, but only a part of total NC–D–RNA (nucleolar D–RNA) was recovered by their method In the course of further examination of the fractionation of RNA of phenolic nuclei we observed that at temperatures below 50° C it is R–RNA which is predominantly released, D–RNA being bound with phenolic nuclei On this observation the method for preparation of R–RNA and D–RNA of NC-apparatus was based[5] After some modifications the following procedure was finally adopted

(1) *Isolation of phenolic nuclei.* Cell suspension or tissue homogenate in 0 14 M sodium chloride was treated with an equal volume of phenol, *p*H 6, at 4°–10° C After 15 min shaking and after centrifugation, high-molecular weight RNA of cytoplasm and nuclear sap and total low-molecular weight RNA were revealed in the aqueous layer Interphase was collected and repeatedly treated (twice or three times) with phenol *p*H 6–0 14 M sodium chloride (1 1) in the cold The interphase washed contained non-purified phenolic nuclei that may be used as such or purified further by a procedure earlier described[2] In the case of Ehrlich ascites carcinoma cells, the cytoplasmic contaminations in the interphase were negligible

(2) *Thermal fractionation* Phenolic nuclei (purified nuclei or washed interphase) were treated by shaking in phenol *p*H 6–0 14 M sodium chloride at 40°–45° C for 20 min, and the main part of R–RNA of NC-apparatus was released The same procedure was repeated at 55° C, the RNA liberated being a mixture of R–RNA and D–RNA Interphase was washed once in the same system in the cold and again treated with phenol, *p*H 6–0 14 M sodium chloride at 60°–65° C Under these conditions D–RNA passed into the aqueous layer

The fractions were referred according to temperature intervals in which they were obtained Thus, 10° C fraction possessed cytoplasmic RNA, 10°–40° C or 10°–45° C fractions—R–RNA (with coefficient $K = G + C/A = U =$ 1 5–1 6) and 55°–60° C or 55°–65° C fractions —D–RNA ($K =$ 0 75–0 85)

(3) *Purification of RNA fractions* For the inhibition of RNase traces, if present, sodium dodecyl sulphate is added to all fractions, and solutions are repeatedly deproteinized with phenol and chloroform RNA was

Table 1. BASE COMPOSITION OF NC–RNA FRACTIONS

Tissue	Type of fractionation	RNA fraction	Base composition of RNA fraction in the whole: Mol per cent of base *G*	*C*	*U*	*A*	$K=\frac{G+C}{A+U}$	Base composition of newly formed RNA in fraction: Mol per cent of base *G*	*C*	*U*	*A*	$K=\frac{G+C}{A+U}$
Ehrlich ascites carcinoma	Phenol	NC–R–RNA (10°–40° C)	32.6	29.9	18.8	19.3	1.67	30.8	30.3	22.6	16.3	1.57

Mice with Ehrlich ascites carcinoma and rats were injected intraperitoneally with ^{32}P (200 and 50 µg/animal respectively). 30–60 min later the animals were killed and RNA fractions were isolated from carcinoma cells of mice and from rat liver by the phenol method or by salt fractionation of isolated nuclei (ref. 8). RNA fractions were washed with 5 per cent TCA on 'Millipore' filters (Rufs), the material of filter was removed by acetone, and RNA was hydrolysed by 0.5 *N* potassium hydroxide (37° C 18 h) and 2′,3′-nucleotides were separated by paper chromatography into four spots (ref. 9). Spots were excised, counted, eluted and measured spectrophotometrically.

precipitated once by ethanol and once by 2.5 M sodium chloride at 0°–4° C and treated with DNase (Worthington). The DNase was removed by shaking with phenol and RNA was reprecipitated 2–3 times by ethanol in the presence of 0.005 M versene. It was stored under the 70° ethanol at −20° C. The yield from 100 ml. of ascites was about 2 mg of R–RNA and 1 mg of D–RNA.

The specific activities of both RNAs were much higher than that of 10° C-fraction (RNA of cytoplasm + nuclear sap). Thus, this fractionation yielded two types of rapidly labelled RNA of the cell.

It is important that the base composition of these preparations, estimated on the basis of ultra-violet absorption of nucleotides (composition of the whole fraction) and estimated on the basis of radioactivity of 2′,3′-nucleotides after short labelling with phosphorus-32 (composition of the newly formed RNA), coincide (Table 1).

Therefore (1) Rapidly labelled nascent RNA of the animal cell is a mixture of D–RNA and R–RNA that may be separated experimentally, (2) our method is suitable for the separation of both total NC–RNA and newly formed NC–RNA into D- and R-fractions.

Some properties of R–RNA and D–RNA of nucleolo-chromosomal apparatus. During recent years many papers have been published concerning total rapidly labelled RNA[8]. It was shown to differ from ribosomal RNA with respect to molecular weight. Some authors claimed it as 'messenger RNA'. However, as shown here, this RNA consists of two types of molecules. Therefore, experiments were carried out in which separated D–RNA and R–RNA were ultracentrifuged in sucrose-density gradient[9]. The results are presented in Fig. 1.

In accordance with our previous results[4], R–RNA contains two components with sedimentation constants equal to 18 and 28 *S*, respectively. Thus, the bulk of R–RNA of phenolic nuclei is a typical ribosomal RNA. However, some material of this fraction sediments at higher velocity. Distribution of radioactivity depends on the time of incubation. In short impulses, all radioactivity is found in heavy 45–35 *S* components. In longer impulses it is also revealed in ribosomal RNA. The total newly formed RNA of R–RNA fraction and newly formed RNA isolated from 18–28 *S* and 35–45 *S* components have nucleotide composition of strong *GC*-type.

From these results the conclusions can be drawn that (1) our fractionation method makes possible the isolation of non-degraded R–RNA of NC-apparatus: the heavy components (45–35 *S*) are not affected by this method, (2) the heavy 45–35 *S*′-component is R–RNA which seems to be a precursor of ribosomal R–RNA[10], (3) the transformation of non-ribosomal R–RNA (45–35 *S*) to ribosomal R–RNA (18 and 28 *S*) occurs in the NC-apparatus.

In order to determine the site of the R–RNA synthesis in NC-apparatus we analysed the base composition of RNA fractions obtained by the salt fractionation of cell nuclei, isolated in aqueous media[6].

It was shown earlier that residue after extraction of nuclei with dilute and concentrated salt solution contained only nucleoli and 'residual chromosomes'. These structures are built of nucleonemata—the filaments 100 Å in diameter with ribosome-like granules attached to filaments[11]. The RNA of this material is the most active fraction among other nuclear RNA's[6]. Table 1 presents the base composition of this 'nucleolar' RNA. The base composition of the fraction as the whole and that of newly formed RNA are of strong *GC*-type. At sucrose gradient ultracentrifugation two radioactive components of ribosomal RNA type are revealed. Thus the total and newly formed RNA of nucleonemata of nucleoli and residual chromosomes is a typical ribosomal RNA. Nucleonemata and their granules appear to be newly formed ribosomes or ribosomal precursors.

In Fig. 1 the results of ultracentrifugation in sucrose gradient of D–RNA are also presented. D–RNA is a heterogeneous population of molecules with the distribution maximum in the zone of light ribosomal RNA component (about 18 *S*). Radioactivity follows ultra-violet absorption although there is no full correlation between these curves. There are also no significant differences in distribution of radioactivity among preparations of different labelling time. Probably chains of different length with molecular weights of the order of 0.3–1.5 × 10⁶ are synthesized without subsequent division into chromosomes.

Fate of D–RNA and R–RNA synthesized in nucleolo-chromosomal apparatus. Many papers have recently appeared demonstrating that RNA's formed in NC-apparatus were further transferred into the cytoplasm (for reviews, see ref. 12). We shall not discuss this problem in detail, but would like to mention one of the

Table 2. RESULTS OF ACTINOMYCIN EXPERIMENTS

Tissue	RNA fractions	Total activity of fraction (c.p.m.): U–^{14}C or ^{32}P + 30 min	U–^{14}C or ^{32}P + 30 min + actinomycin + 90 min	The change of total activity: c.p.m.	Per cent
Ehrlich ascites carcinoma	D–RNA (50°–65° C fraction)	7,250	5,250	−2,000	−28
	R–RNA (10°–50° C fraction)	18,700	16,200	−2,500	−13
	Cytoplasmic RNA (10° C fraction)	2,240	1,680	−560	−25
Rat liver	D–RNA (50°–65° C fraction)	12,600	6,900	−5,700	−45
	R–RNA (10°–50° C fraction)	6,600	2,175	−4,425	−75
	Cytoplasmic RNA (10° C fraction)	7,650	18,750	+11,100	+145

Ehrlich carcinoma cells were labelled with uridine-^{14}C 30 min *in vitro*, rat liver cells with ^{32}P 30 min *in vivo*. The actinomycin *D* (10 µg/ml. of ascites) or 'Aurantin' (1.5 mg per rat intraperitoneally) were administered. The activity of fractions was studied 30 min and 120 min after adding of precursor. Phenol fractionation was slightly modified for quantitative recovery of RNA fractions.

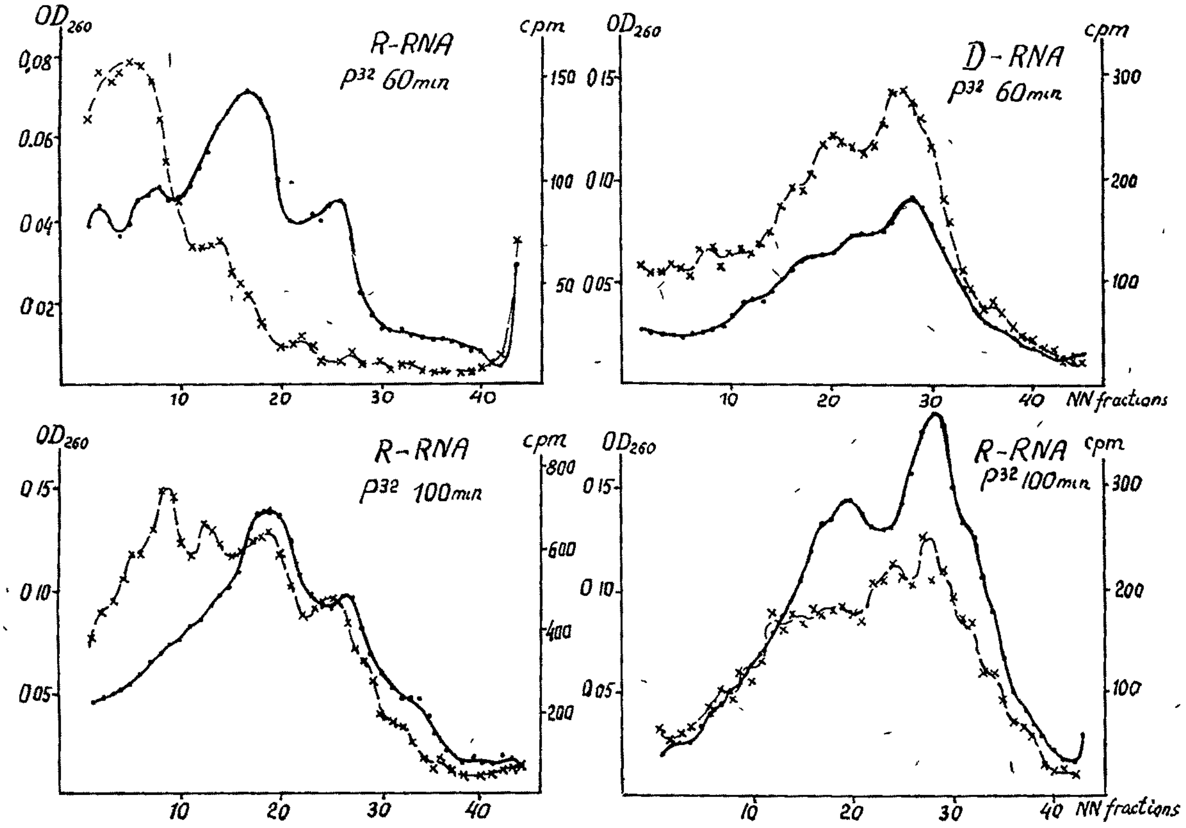

Fig. 1. Sedimentation properties of the NC–RNA fractions. Ehrlich ascites carcinoma cells were incubated with phosphorus-32 *in vivo* (50–100 μc./animal). 1–2 mg of each NC–RNA was ultracentrifuged in *SW*-25 rotor of Spinco-*L* in 5–20 per cent sucrose gradient at 25,000 r.p.m. for 10 h. ——, Ultra-violet absorption; – – –, radioactivity

experimental approaches. We tried to use actinomycin blockage of total RNA synthesis[13] for demonstration of nucleo-cytoplasmic RNA transport. After impulse labelling of cells the actinomycin (actinomycin *D* or 'Aurantin') was administered and redistribution of radioactivity among RNA fractions was investigated.

In two systems tested (Ehrlich ascites carcinoma and culture of human amnion) actinomycin inhibited not only synthesis of RNA but also liberation of RNA from NC-apparatus of the cell. Neither transport nor considerable breakdown (as in Harris's experiments[14]) of rapidly labelled RNA was observed. About 80 per cent of the latter was detained in NC-apparatus (Table 2). However, in the case of rat liver the liberation of RNA is less affected, and actinomycin blockage leads to a rapid and significant decrease in the activity of NC–RNA, especially of R–RNA, and to a corresponding increase in the activity of cytoplasmic RNA. The total activity loss by NC-apparatus roughly equals the activity rise revealed in the cytoplasm. Although some part of NC–RNA was also arrested in the case of rat liver, these results indicate the transport of RNA from the NC-apparatus to the cytoplasm.

But these experiments do not give any insight into the nature of RNA moving to the cytoplasm. As was shown by Hiatt and Monier[8], all labelled cytoplasmic RNA was connected with ribosomal components and 4*S*-component. Base composition of newly formed cytoplasmic RNA was of strong *GC*-type, D–RNA seems to be absent in the cytoplasm. To demonstrate the presence of D–RNA in the cytoplasm of animal cells and thus to prove the possibility of its nucleo-cytoplasmic movement the following experiments were carried out. The biosynthesis of R–RNA was shown to be rather sensitive to actinomycin, as compared with D–RNA formation[15]. It seems possible to inhibit selectively the biosynthesis

Table 3. BASE COMPOSITION OF RNA'S FORMED DURING INCUBATION FOR 6 H WITH ^{32}P IN THE PRESENCE OF 'AURANTIN'

No. exp.	RNA studied	Dose of 'Aurantin' (μg per animal)	Sp. activity c.p.m./mg RNA	Base composition of newly formed RNA: Mol per cent *G*	*C*	*U*	*A*	*K* = G+C/A+U	D–RNA synthesized per cent of total RNA synthesized

		40	—	20.6	25.2	27.6	26.8	0.83	85
		160	—	20.4	22.6	27.1	29.6	0.76	95

The rats were injected intraperitoneally with 'Aurantin' and 40 min later with ^{32}P (0.5–1.0 mc./animal). 6 h later animals were killed and liver RNA fractions were isolated: total RNA—by the treatment with phenol *p*H 6—0.5 per cent sodium dodecyl sulphate at 60° C, cytoplasmic RNA and NC–RNA—as described here. All fractions were reprecipitated by 1.5 M sodium chloride. The method of determination of newly formed RNA is the same as in Table 1. Content of D–RNA synthesized was calculated assuming $K_{D\text{-}RNA}$ = 0.73 and $K_{R\text{-}RNA}$ = 1.73

of R–RNA without affecting that of D–RNA if using small doses of this antibiotic The results are presented in Table 3 In normal rat liver cell nucleotide composition of RNA formed during incubation for 6 h with phosphorus-32 is typical for ribosomal RNA and no signs of the presence of D–RNA are revealed But in the case of partial inhibition of RNA synthesis $K = G + C/A + U$ is lowered and reaches 0 8 It means that about 90 per cent of RNA synthesized in these conditions represents D–RNA If the RNA from these cells is divided into NC–RNA and cytoplasmic RNA it can clearly be observed that D–RNA is present not only in nuclei but also in the cytoplasm (Table 3) Preliminary results of the fractionation of the cytoplasmic RNA on methylated serum albumin support this view In the cytoplasm of a normal cell non-ribosomal RNA cannot be detected after labelling for 6 h, but in a partially inhibited cell a distinct non-ribosomal RNA–component with some lower molecular weight can be observed

When this work was completed the report of Penman *et al* [16] appeared demonstrating the presence of D–RNA in polysomes These results indicate that D–RNA formed in the cell nucleus transits into the cytoplasm, where it can be detected Further work on this transport and transformations of D–RNA in the nucleus and the cytoplasm is in progress.

FUNCTION OF THE THYMUS AND GROWTH OF TUMOUR HOMOGRAFT

By Dr G. C. PERRI, M FAULK, E SHAPIRO, J. MELLORS
and Dr W. L. MONEY

Divisions of Experimental Chemotherapy and of Clinical Investigation,
Sloan-Kettering Institute for Cancer Research and Sloan-Kettering
Division of Cornell University Medical College, New York 21

THE development of a normal immune system has been shown to be dependent on the presence of the thymus gland[1–4] Thymectomy performed at birth in experimental animals is followed by a severe depletion of the lymphocyte population in both the spleen and lymph nodes, and animals so treated show serious immunological defects; homograft acceptance by such animals is significantly increased[5–9] Thus, available data support the concept that the absence of the thymus gland during the post-natal period produces a depression of the immunological reaction sufficient to suppress the skin homograft rejection mechanism Recent reports suggest that in the thymus two factors are present, one accelerates the growth of neoplastic tissue and another slows neoplastic growth[10,11] It is also possible that the thymus regulation of the maturation of immunologically competent cells[12–14] may be of humoral nature

The thymus and its function could be of particular importance in the field of oncology since it might participate, along with other glands, in the regulation of tissue homœostasis and be of paramount importance in repressing the activity of cells which potentially may develop into neoplasms

If the thymus is involved in the immune reaction, it might be expected that the growth pattern of the tumour would be changed in thymectomized animals It seemed, therefore, of interest to examine the effect of thymectomy on the growth of a transplantable tumour For this investigation on rats we have used Jensen sarcoma which, on the basis of its origin and host relationship, can be considered a homograft

More than 300 male and female rats of the Sprague–Dawley strain (Charles River) were used in this work, and each experiment repeated several times with consistent results (Table 1) The general pattern of the experiments was as follows Pregnant rats were maintained under normal laboratory conditions until the young were delivered Litters were pooled and animals thymectomized on a random basis regardless of sex within 48 h after birth under light ether anæsthesia through an incision in the neck and the upper sternal cartilage which was closed with skin clips and covered with collodion to ensure maternal care Jensen sarcoma was implanted by trocar

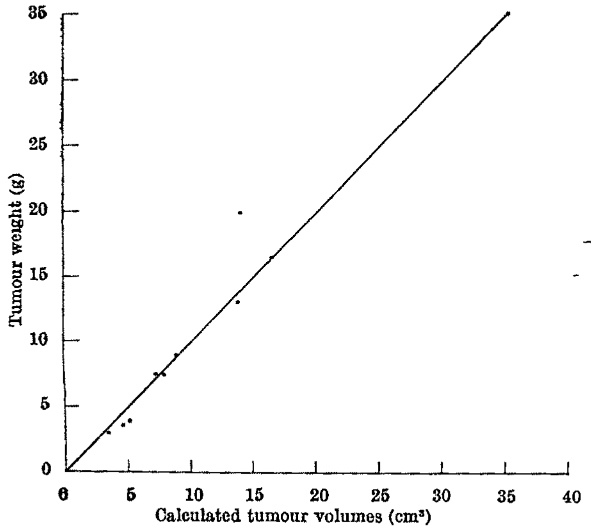

Fig. 1. Correlation between tumour volumes (cm³) calculated and tumour weight at autopsy, $r = 0\ 93$

or as a minced suspension into animals of different ages When implants were made beyond 20 days of age the animals were weaned and transferred to separate cages, otherwise the young were left with the mother until completion of the experiment Body weight and tumour diameters were recorded daily Loss of weight was observed in animals at weaning or on transfer to single cages; otherwise the growth curve was quite regular About 12–14 days after implant of the tumour the animals were killed and those showing signs of incomplete thymectomy or infection were discarded.

Several ways of calculating tumour volumes from the daily measurements were tried. Although theoretically the tumour volume should be better expressed as that of an ellipsoid of revolution, neither the formula for oblate nor for prolate spheroid is applicable Values obtained by the former were higher and for the latter lower than the weight obtained at autopsy However, a good correlation was found between the calculated volume (cm³) and weight (g) when the tumour volume was considered equal to a solid having the length of the major axis *a*, and the height and width equal to the minor axis *b* In fact, when the formula $V = ab^2$ was used the correlation coefficient obtained by plotting the weights of the tumour against the calculated volume was equal to 0 93 It can be seen (Fig 1) that the discrepancy between the two sets of values increases with tumour weights above 20 g

Thymectomy in non-tumour-bearing new-born rats did not produce any significant change in the growth rate of the animals during the time of these experiments, the body weights of the thymectomized and control animals were comparable within normal variations. Furthermore, the subsequent mortality of animals thymectomized at birth was less than 5 per cent, and those that died or were discarded because of extreme loss of weight showed substantial infection, usually in the thoracic cavity

Fig 2 shows the rate of growth of Jansen sarcoma in thymectomized and control animals Although the tumours in both groups became measurable at approximately 7 days after implant, the growth curves diverged markedly around the tenth day By the fourteenth day the tumours in thymectomized animals were 2–3 times greater than in the controls, and showed striking macroscopic differences in appearance In control tumours the tissue showed the usual appearance of necrosis in the central portion and peripheral proliferating tumour of transplants of Jensen sarcoma at this stage of growth, whereas tumours in thymectomized animals showed little or no evidence of necrosis, the entire mass consisted of typical Jensen sarcoma tissue

In the normal control rats the percentage of successful transplants was the 75 per cent usually observed with Jensen sarcoma In the thymectomized groups, on the other hand, transplants were 100 per cent successful with the exception of one group with 88 per cent success. Table 1 summarizes the results of this experimental group of 25 thymectomized rats and 25 unoperated littermates implanted with the same pooled tumour tissue from 14-day-old Jensen sarcoma, and shows that 24 per cent of the tumour implants in the normal animals were rejected with no trace of the implant on autopsy Of the remaining implants, 36 per cent grew but were regressing (weight less than 5 g at 14 days) and 40 per cent were fully growing In the thymectomized rats 12 per cent of the implants were rejected, 12 per cent were considered regressing, and 76 per cent had become fully growing tumours (more than 5 g).

Our results show clearly that Jensen sarcoma grows in rats thymectomized at birth at a significantly faster rate than in normal animals Implantation of the tumour in splenectomized new-born animals (unpublished data) gave results identical to normal rats and implants in splenectomized and thymectomized animals did not differ significantly from results obtained in animals thymectomized only Thus the normal aggressive growth of this type of tumour is definitely enhanced by thymectomy That thymectomy significantly modifies the behaviour of Jensen sarcoma is clearly shown by the slope of the growth-curve, by the increased percentage of successful transplants, and by the weight of the neoplastic mass at autopsy, and is further supported by the macroscopic appearance of the tumour masses in thymectomized rats, masses practically free of necrotic areas in contrast to Jensen sarcoma of the same age grown in normal animals The present data are consistent with the results reported by Martinez *et al*[6] obtained with tumour homografts in thymectomized mice

The Jensen sarcoma homograft in normal animals is capable of overcoming the histo-incompatibility barrier of the host Sprague–Dawley rat in 75 per cent of the cases, but the host immune reaction makes possible the regression and outright rejection of some of the implants with time. Those implants which grow show extensive hæmorrhagic and necrotic areas In thymectomized animals the number of rejections and regressions of the tumour implants is significantly lower and the hæmorrhagic and necrotic component is virtually absent It is rather unlikely that the necrotic areas of the tumour growing in normal rats are caused by circulatory insufficiency or accumulation of catabolites since such areas do not appear in tumour

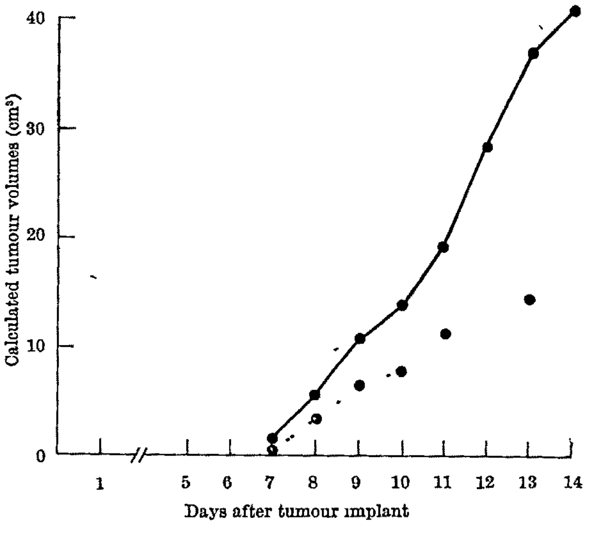

Fig 2. ——, Thymectomized tumour-bearing rats, – – –, control tumour-bearing rats

masses growing more rapidly, and to larger volumes, in thymectomized animals. Therefore, it seems plausible to consider all these signs as significant indication that thymectomy has abolished, or greatly depressed, some of the immune reactions of the host. Jensen sarcoma seems to grow in thymectomized animals in a more uncontrolled and unchallenged fashion as if a repressing factor had been removed. From the slope of the growth curve obtained in 76 thymectomized and 61 control animals it can be calculated that the daily growth rate of Jensen sarcoma in thymectomized animals is 1.8 times higher than in normal animals.

The present evidence adds additional support to the concept that the thymus gland in the post-natal period is important for normal development of the immune reaction, but the mechanism of its action is not clear. While the lymphocyte migration theory has not been directly demonstrated in the development of the immune system, the humoral theory[12] has received support[13,14]. Although additional evidence such as the demonstration that spleen tissue does not have such an effect is needed, other results strongly support the humoral theory. For example, histological examination of the thymus shows epithelial cellular formations containing granules localized around capillaries and with a characteristic relationship to reticular fibres, that can be considered capable of a secretory function. Such formations, easily seen in the thymus of reptiles after hibernation[15,16], when the thymus is depleted of lymphocytes, and also described in the calf[17,18], are evidence in favour of a secretory function of the thymus. This might imply that the thymus gland has not only the postulated function of responsibility for the development of the immune system in post-natal life, but possibly also a more general and complex function yet to be defined. Recent reports[10,11] suggesting that the thymus gland contains substances which affect the rate of growth of cells may ultimately help to resolve these questions.

EXCRETION AND THE ACCRUAL OF DRUG METABOLITES

By A. J. CUMMINGS and DR. B. K. MARTIN
Nicholas Research Institute, Ltd., Slough, Bucks

THE relationship of the rate of decline of a drug in the plasma to the rate of excretion of unchanged drug in the urine has been established in respect of a number of drugs, for example, sulphaethylthiadiazole[1] and tetracycline[2]. A similar study of the rate of excretion of metabolites when a drug is excreted predominantly as metabolites is more complex, for this involves the specific rate constants for metabolite formation (k_f) and for metabolite excretion (k_e).

When a drug is rapidly metabolized and the metabolite is slowly excreted, that is $k_f > k_e$, the concentration of the metabolite may eventually exceed that of the parent drug to become the only form of the drug in the body, and there will ultimately be a period when only the metabolite is excreted. The urinary excretion data may then permit the calculation of k_e. When, however, a drug is slowly metabolized and the metabolite is rapidly excreted, that is when $k_f < k_e$, the drug and the metabolite will always be excreted together and the observed rate of metabolite excretion is a function of k_f and k_e.

This article relates to k_e under the conditions when $k_f < k_e$ and points to its significance in the explanation of certain observations.

Little consideration appears to have been given to those instances where the metabolite is believed to be 'rapidly excreted'. It has sometimes been assumed that when excretion is rapid, the rate of excretion of the metabolite can be equated to its rate of formation. The two processes may ultimately decline in parallel, but this is not so in the early phase of excretion and they are equal only at one particular time.

Butler[3] has shown that in theory the half-life ($t_{0.5}$) of a substance excreted by the kidney can be related to its renal clearance (C) and its apparent volume of distribution (V_d), by the expression

$$t_{0.5} = \frac{V_d}{C} \ln 2$$

Metabolite formation is considered to be an intracellular reaction and, while this may be limited to certain cells, the probability must be considered that the metabolite may then enter other cells. The apparent volume of distribution of a metabolite will therefore exceed the extracellular water volume and may well approach that of total body water. A metabolite exhibiting the maximum renal clearance ($C = 700$ ml./min.) but having a high apparent volume of distribution ($V_d = 50$ l.) would have a half-life of 50 min, that is, only 56 per cent would be excreted each hour.

After the administration of salicylic acid, the major metabolite in human urine is salicyluric acid. The oral administration of salicyluric acid (0.5 g), and calculation of $t_{0.5}$ from the excretion data, gives a value for salicyluric acid of about 50 min. This metabolite is 'rapidly excreted', yet of that present at the beginning of an hour little more than 50 per cent will be excreted during the hour, while of that formed in the course of the hour the percentage excreted will be even smaller.

The rate of formation of a metabolite may be calculated from the rate of decline of the concentration of drug in the plasma, after allowing for the decline due to excretion of the unchanged drug. In the first hour after drug administration the quantity of metabolite formed will be greater than the amount excreted and some will remain in the body to be added to that formed in the next hour. Present concepts imply that metabolite formation will usually reach its maximum when the concentration of drug is at its maximum, thereafter, it will decrease. The amount of metabolite which remains from the previous hour may, however, be more than sufficient to compensate for the

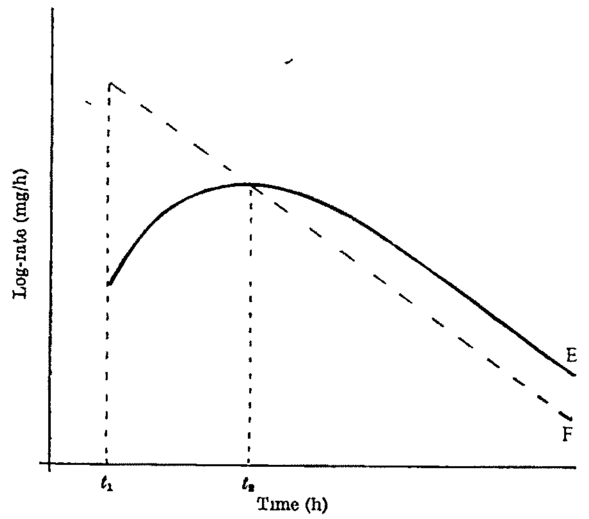

Fig. 1. Rate of metabolite excretion is depicted by the line *E* and rate of metabolite formation by line *F*. Maximum plasma concentration of drug occurs at time t_1, maximum rate of excretion of the metabolite at time t_2

decrease in the amount formed, and, if so, the accrual of metabolite will continue. The maximum rate of excretion of the metabolite will occur when the plasma metabolite concentration reaches its peak and this may therefore occur much later than the peak drug concentration. The magnitude of metabolite accrual depends not only on the relationship of k_e to k_f, but also on the rate of absorption, for three consecutive processes are involved. After the maximum rate of excretion has been attained, the quantity of metabolite excreted per hour exceeds the amount formed per hour.

A plot of log amount of metabolite excreted per hour against time ultimately approximates to a straight line (Fig. 1). The slope of this line can then be closely identified with that of the log rate of metabolite formation and it provides an accepted basis for the calculation of k_f. If the excretion of metabolite reaches its maximum when its concentration in plasma is maximum, this will occur when its rate of formation and excretion is equal. The plots of log rate of metabolite formation and log rate of metabolite excretion will therefore intersect at the point where the latter is maximum. On the basis of these considerations the line representing the log decline of metabolite formation may be positioned approximately (Fig. 1).

In a previous communication[4], we reported that whereas peak plasma salicylate-levels may be attained about 1 h after the oral administration of aspirin, the maximum rate of 'total salicylate' excretion does not occur until the third hour or later. Elimination of salicylic acid from the body is slow and depends almost entirely on the formation of metabolites. The apparent delay in their excretion may be attributed to metabolite accrual.

A consideration of excretion rate constants may also provide an explanation of the urinary findings when a drug gives rise to more than one metabolite. Each metabolite has a specific excretion rate constant and each will consequently attain its maximum rate of excretion at different times. A plot of log rate of excretion of each metabolite would be expected ultimately to provide a set of parallel lines. Similarly, a log plot of the rate of excretion of total metabolites will only become linear when the foregoing state has been realized and will then parallel the log rate of decline of the drug in plasma. The excretion of total metabolites is a composite function and for this reason may show a number of variations until the individual metabolites are excreted in constant ratio.

The foregoing considerations can be related to the observed excretion of salicylate metabolites in urine. Schachter[5] and Schachter and Manis[6] have shown that after the administration of sodium salicylate the ratio of the metabolites in the urine varied with time. This might suggest that the rate of formation of one or more of the metabolites varies with time or with plasma salicylate concentration. Cummings[7] has suggested that salicyluric acid shows an apparent change in its rate of formation as the plasma salicylate concentration increases. This will cause a change in the ratio in which the metabolites are formed and excreted. An additional explanation is, however, necessary, for a plot of log rate of excretion of 'total salicylate' against time does not become linear for several hours after a small dose (0.3 g) of aspirin. This dose provides a plasma salicylate concentration below that at which the rate of formation of salicyluric acid shows an apparent change. The observed excretion pattern can be explained on the basis that the metabolites are initially excreted in varying ratios in accordance with the foregoing theory. It is not necessary to postulate the delayed formation of one or more metabolites, for the uniform decline in log plasma salicylate during this period indicates that the metabolites are formed at uniform rates.

DETERMINATION OF CEREBRAL BLOOD FLOW BY A KRYPTON-85 DESATURATION METHOD

By Captain LAWRENCE C. McHENRY, jun.
Department of Neurophysiology, Walter Reed Army Institute of Research, Washington, D.C.

SINCE the development of the nitrous oxide technique by Kety[1] in 1945 for the quantitative determination of cerebral blood flow there have been a variety of new methods proposed for the examination of the cerebral circulation. Except for the krypton saturation technique of Lassen and Munck[2] most newer methods do not give specific quantitative data or are technically difficult to perform.

A desaturation method based on the Fick principle for determination of cerebral blood flow was originally considered feasible by Kety[3], but was not utilized until reported by Lewis *et al.*[4] In 1960, Lewis *et al.*[4] described both nitrous oxide and krypton-79 saturation and desaturation methods. In 1961, Kempinsky[5] reported using a nitrous oxide desaturation method, but did not give normal values for the method.

The krypton-85 desaturation method for cerebral blood flow determination was developed for three reasons First, when the saturation methods of Kety or Lassen are used, smooth curves are obtained only by maintaining a constant concentration of inert gas during inhalation. This is easily done when using nitrous oxide, but when using krypton-85 or krypton-79 special equipment is needed to maintain a precise concentration of the tracer In the desaturation method the maintenance of precise concentration of inert gas during saturation is unnecessary. When a desaturation investigation is carried out, mask leaks during saturation are unimportant, and no special equipment is needed to administer the tracer

Secondly, since there is no mask on the patient's face during the actual examination of cerebral blood flow, respiration is unimpeded and any influence of anxiety on cerebral hæmodynamics is reduced Thirdly, by using a desaturation technique the effect of extra-cerebral contamination of measurement of cerebral blood flow is minimized. This is the most important reason for using the desaturation technique, in addition to the ability to do away with the face mask[6]

The method is based on the Fick principle and is essentially a modification of the Kety–Schmidt technique In order to carry out the desaturation procedure, the brain is first saturated with approximately 8 μc of krypton-85 by re-breathing it for 7 min in the closed circuit of a BMR machine or portable anæsthesia machine

During the last minute of saturation, prior to removal of the face mask, continuous internal jugular venous and arterial blood samples are obtained to estimate the quality of krypton in the brain at the end of saturation After removal of the face mask, continuous 1-min jugular venous and arterial blood samples (3 c c each) are drawn during the first 2 min of desaturation Individual 3 c c blood samples are then obtained during the remaining desaturation period at the end of the 2nd, 3rd and 4th min and thereafter every 2 min to the 12th min A 12-min desaturation period was chosen to provide a slightly longer period of examination than in the original 10 min of the nitrous oxide method This may be of particular value in patients with a lowered cerebral blood flow

Blood samples are obtained in 10 c c oiled-heparinized syringes via 5-stopcock manifolds After removal of the syringes from the manifolds, 7 c c of air are drawn into each syringe to a total of 10 c c (3 c c blood–7 c c air) Since krypton is 25 times more soluble in air than in blood, more than 90 per cent of the krypton is released into the air-phase The air-phase is then injected into a glass-jacketed Geiger–Muller tube by the displacement of mercury and counted on a standard scaler

The concentration of krypton or the counts per min of each sample is plotted against time as shown in Fig 1 The cerebral blood flow (CBF) is calculated using the Fick equation*:

$$\mathrm{CBF} = \frac{(C_t/W) \times \lambda \times 100}{\int_0^{12} (C_v - C_a)\,dt}$$

The (C_t/W) is assumed to be equal to the concentration of krypton in the venous blood at the end of saturation (C_{v_s}) minus the concentration at the end of desaturation (C_{v_d}):

$$C_t/W = C_{v_s} - C_{v_d}$$

The blood brain partition coefficient for krypton, λ, has been calculated by Lassen[2] It is constant from individual to individual with a normal hæmoglobin level and is only slightly above unity, that is, 1 06 A value for λ of 1 00 was used in these investigations In patients with anæmia or polycythæmia the partition coefficient must be taken into consideration when calculating the cerebral blood flow

Table 1

	Mean	*S D*
Cerebral blood flow (CBF), c c blood/100 g brain/min	56 5	7 7
Cerebral vascular resistance (CVR), mm Hg/c c blood/100 g brain/min	1 52	0 89
Cerebral metabolic rate ($CMRO_2$), c c O_2/100 g brain/min	3 37	0 5

$$\mathrm{CBF} = \frac{(C_{v_s} - C_{v_d}) \times 100}{\int_0^{12} (C_v - C_a)\,dt}$$

Using the krypton desaturation method, investigations of the cerebral circulation were performed on 25 normal males (mean age 27 years) with the results shown in Table 1 The mean arterial carbon dioxide tension during these investigations was 45·93 volumes per cent with *S D.* 2 94 A typical normal desaturation curve is shown in Fig 1

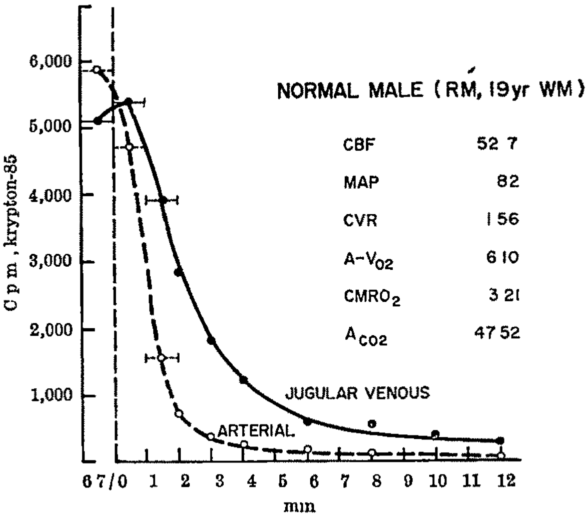

Fig 1 A krypton-85 desaturation curve in a normal male CBF, cerebral blood flow, c c blood/100 g brain/min, MAP, mean arterial blood pressure, mm mercury, CVR, cerebral vascular resistance, mm mercury/c c blood/100 g brain/min, A-V_{O_2}, arteriovenous oxygen difference, volume per cent, $CMRO_2$, cerebral metabolic rate, c c O_2/100 g brain/min, A_{CO_2}, arterial carbon dioxide content, volumes per cent

In order to test the reproducibility of the method, two cerebral blood flow investigations (o) were performed on the same individual, one after the other at an interval of 10 min The mean values for five cases were (1) 55 3 c c and (2) 56 2 c c The individual values (o) are plotted in Fig 2 and indicate a high degree of reproducibility

In order to evaluate the period of time required for brain saturation prior to the desaturation investigations, two cerebral blood flow investigations (×) were performed on six patients The first was done after 7 min saturation and the second after 15 min saturation. The mean value for the first (1) cerebral blood flow was 45 4, and for the second (2) 44 2 The results (×) of this work are also shown in Fig 2 Although the mean CBF values obtained are quite close, in a patient with low CBF there was a decrease of 15 per cent between the first, 17 3 c c, and second, 14 7 c c, CBF value obtained after longer saturation This demonstrates that in patients with diminished cerebral circulation or metabolism a longer period of saturation is necessary prior to the examination of cerebral blood flow

This method, based on the Fick principle, is essentially a modification of the inert gas method of Kety and Schmidt Instead of measuring the arteriovenous difference during saturation of the brain, arteriovenous

---

* C_t = concentration of krypton-85 given off by the whole brain during 12 min desaturation measured from the end of saturation C_v = concentration of krypton-85 in the cerebral venous blood during 12 min desaturation C_a = concentration of krypton-85 in the arterial blood during 12 min desaturation C_{v_s} = concentration of krypton-85 in the cerebral venous blood at the end of saturation C_{v_d} = concentration of krypton-85 in the cerebral venous blood at the end of desaturation W = weight of brain λ = blood brain partition coefficient for krypton

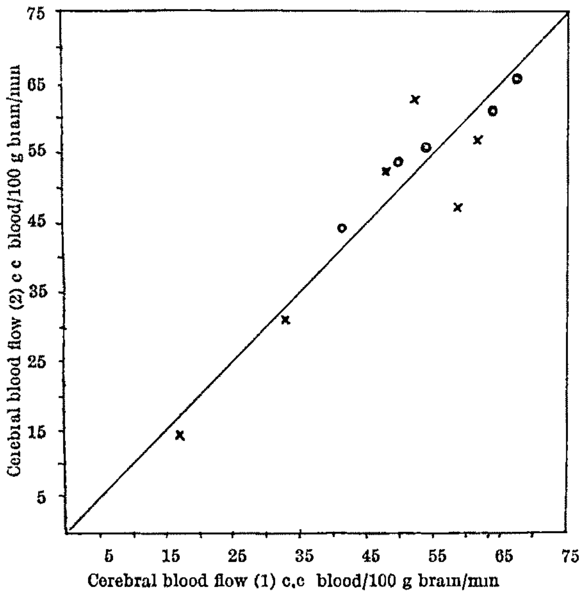

Fig 2 Values (O) obtained from two cerebral blood flow investigations performed on the same normal individual (1) after the other (2) at a 10-min interval preceded by 7 min saturation Values (×) obtained from two cerebral blood flow investigations on the same patient at a 10-min interval preceded by (1) 7 min saturation and by (2) 15 min saturation

differences during desaturation are measured The denominator of the Fick equation is the integral of the veno-arterial krypton difference during desaturation. The numerator of the equation is the concentration of krypton in the venous blood at the end of saturation minus the amount remaining in the venous blood at the end of desaturation

The value for cerebral blood flow, 56 5 c c , obtained by this method is similar to values reported by Lewis *et al* [4] Using krypton-79 desaturation, they obtained a mean CBF value of 57 3 c c A simultaneous nitrous oxide desaturation mean CBF value was 57 5 c c These values are slightly higher than that, 54 c c , obtained originally by Kety and Schmidt[1] using nitrous oxide saturation, but are less than the mean CBF value, 65 c c , obtained by the Scheinberg and Stead[7] modification. The mean values for cerebral metabolic rate, 3 37 c c oxygen, and for cerebral vascular resistance, 1 52 mm mercury, obtained by this krypton-85 desaturation method are similar to accepted values

The validity of the desaturation method will primarily depend on the length of time of saturation prior to the desaturation investigation Since inert gas equilibrium between blood and brain actually takes less than 10 min (about 7 min) to occur[8], a 7-min period was chosen as the minimal saturation time for normal individuals Although only based on six determinations, the actual comparison of mean cerebral blood flow values after 7 and 15 min saturation would indicate that 7 min is probably adequate for normal individuals On the basis of theoretical and empirical evidence outside of these results[6], however, a period of 10–15 min would be preferable, particularly when abnormalities of the cerebral circulation are being investigated

I thank Drs Niels Lassen, Louis Sokoloff and S. S Kety for their advice

EFFECT OF KINETIN ON SENESCENCE AND ABSCISSION IN EXPLANTS OF *PHASEOLUS VULGARIS*

By DAPHNE J OSBORNE and SUSAN E. MOSS
Agricultural Research Council Unit of Experimental Agronomy, Department of Agriculture,
University of Oxford

MUCH of our knowledge concerning the effects of plant hormones and related substances on abscission has been derived from observations on the abscission of leaves and other parts of whole plants, and from examination of the control of separation in excised segments of petioles or stems which contain abscission zones These segments are usually referred to as 'explants'

Depending on the concentration, and the position of application relative to the abscission zone, the auxins indolyl-3-acetic acid or 2,4-dichlorophenoxyacetic acid will either accelerate or retard separation at the abscission zone both in intact plants of *Gossypium* or *Phaseolus* and in their explants[1] The effect of gibberellin on *Gossypium* explants is similarly dependent on the concentration and position of application[2] A low concentration of ethylene in the surrounding air normally accelerates the abscission of leaves in intact plants[3,4], as well as accelerating separation in abscission zones of explants[5] A number of naturally occurring, non-volatile substances isolated from plant tissues will also accelerate abscission in *Phaseolus*[6] or *Gossypium* explants[7]

From a consideration of the effects of these different kinds of substances on abscission it would seem that there are certain features of cellular physiology which are common to the processes of separation, and that abscission occurs only when these conditions are fulfilled Many workers have already pointed out that abscission of an organ is associated with senescence of that organ, and that separation is dependent on senescence in the abscission zone itself[8] Provided that the senescent condition is attained, the nature of the agent which brings about senescence is not critical to the actual processes of separation For example, it has been shown[5] that separation of abscission zones in leaves or explants of *Phaseolus* does not occur so long as there is a gradient of pectinmethylesterase activity from the pulvinar to the petiolar side of the zone, but during abscission this gradient changes, and at separation the pectinmethylesterase activity on either side of the zone is the same These changes can be induced by ethylene, by a number of different chemical defoliants or by complete removal of the leaf blade

It seems unlikely that abscission can be directly controlled by such different causal agents, it is more likely that each of these treatments results in similar kinds of biochemical changes in the cells of the abscission zone A decline in the total protein content and a loss of chlorophyll, both symptoms of senescence, have been demonstrated during abscission in *Phaseolus* explants[5], particularly in the parts distal to the zone Evidence of this kind suggests that separation of the cells at an abscission zone should be examined in the wider physiological context of cellular senescence

This article records some experiments with the plant growth regulator kinetin, and the results support the view that abscission in explants of *Phaseolus* is primarily a problem of cellular senescence at the abscission zone

One segment, 1 cm long, was cut from the leaf-stalk of each of the two fully expanded primary leaves of 14-day-old plants of *Phaseolus vulgaris* Each segment included the whole of the distal pulvinus, the abscission zone and part of the petiole below the zone The segments were arranged, groove side up, on notched 'Perspex' racks embedded in 3 per cent agar in 9-cm Petri dishes[5] The segment from one primary leaf of each plant was treated and the segment from the other leaf was a control Twelve treated and twelve corresponding control explants were arranged in each Petri dish, and at least two dishes were used for each treatment in each experiment The individual experiments were repeated many times

Kinetin was made up in aqueous solution at 10, 25 and 50 mg/l and measured drops of this solution were applied to either the pulvinar, the petiolar or to both ends of the explants with an Agla micro-syringe fitted with a Vernier attachment Similar volumes of distilled water were added to each control segment The dishes were kept

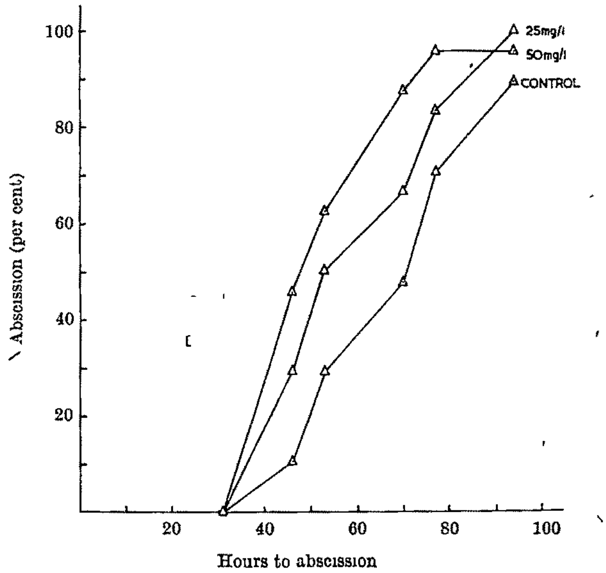

Fig 1 Acceleration of abscission by application of 0 002 ml of aqueous kinetin solution (50 mg/l and 25 mg/l) to the pulvinar ends of explants of *Phaseolus* Controls treated with water

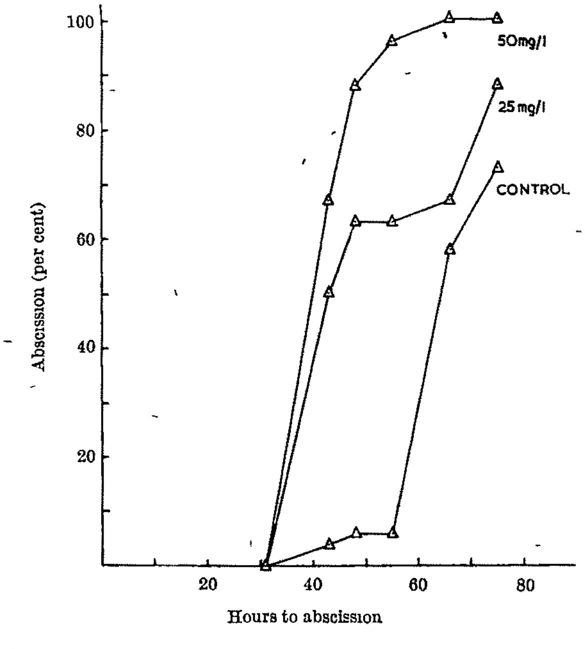

Fig 2. Acceleration of abscission by application of 0 002 ml of aqueous kinetin solution (50 mg/l and 25 mg/l) to the petiolar ends of explants of *Phaseolus* Controls treated with water

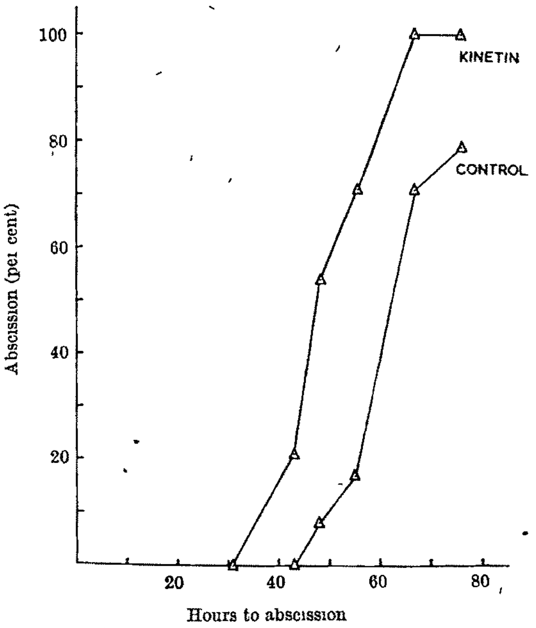

Fig 3 Acceleration of abscission by application of 0 001 ml of aqueous kinetin solution (50 mg/l) to both pulvinar and petiolar ends of explants of *Phaseolus* Controls treated at both ends with water

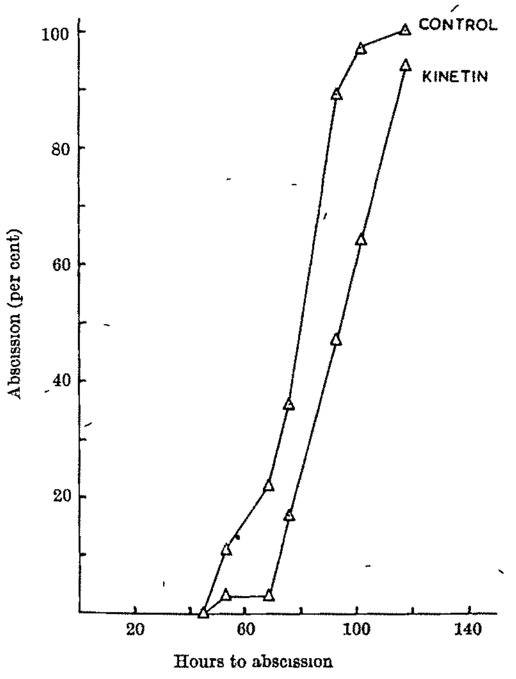

Fig 4 Retardation of abscission by application of 1 per cent kinetin in lanolin directly to the abscission zone of explants of *Phaseolus* Controls treated with plain lanolin

under humid conditions in a dark room controlled at 24·5° C The number of explants which had separated into two parts at the zone of abscission was recorded at intervals, and the results are expressed in Figs. 1–4 as percentage abscission against the time in hours from the start of the experiment

When kinetin is supplied to the ends of the explant, abscission is accelerated Applications of 0 002 ml drops containing 25 or 50 mg/l kinetin to the pulvinar (Fig 1) or petiolar (Fig 2) ends, or of 0 001 ml drops to both ends (Fig 3), cause more rapid abscission At the lowest concentration (10 mg/l), kinetin did not affect the time of separation

Applications of kinetin directly to the abscission zone, however, retard separation Here, a narrow ring of lanolin containing 1 per cent kinetin, encircling the line of separation between pulvinus and petiole, effectively delays abscission compared with controls treated with plain lanolin (Fig 4)

These results show that, dependent on the position of the application, kinetin can either accelerate or retard abscission The observed dual role of kinetin is therefore not unlike that of auxins and gibberellin, both of which accelerate or delay abscission depending on their position of application and the concentration supplied

In view of the differences in the chemical constitution of these different growth regulators and their known differences in physiological activity in plant tissues, their role in abscission processes is sought in some function which is common to them all.

The retardation of senescence in leaf tissue by treatment with auxins[9], kinins[10] and gibberellins[11] has been reported for a number of different species For auxins and kinetin, this effect has been associated with a maintenance of protein and nucleic acid synthesis[12,13] The treated areas have also been shown to act as loci for the accumulation of both organic and inorganic substances For example, endogenous metabolites accumulate in the parts of individual leaves treated with an auxin[14] or kinetin[15], while exogenously applied substances have been shown to move more readily into, or to be retained more readily within, those parts that have been treated with an auxin[16] or kinetin[17].

Very low doses of an auxin may well become immobilized at the cut ends of the explant to which they are supplied[1,18], or, particularly for proximal applications, the auxin may fail to be transported the length of the segment[19] Under these conditions the ends which are treated with auxins might then function as loci of accumulation Any accumulation of essential metabolites at, or near, these cut ends may well involve the depletion of other parts of the segment Since abscission zone cells will frequently separate before complete senescence of a leaf blade it is possible that the abscission zone is particularly sensitive to the withdrawal of some essential metabolites, which results in an accelerated senescence and separation When higher doses of an auxin are supplied[1,18], all the cells of the explant may receive a sufficient supply of the auxin to prevent movement of metabolites from any one part to another, and therefore premature senescence in the abscission zone should not occur In fact, abscission is then retarded This can be associated with the known effect of auxins in retarding senescence in excised leaves[9] and with the more recent findings[12] that auxins maintain protein synthesis in leaves under these conditions

It is proposed that the effects of kinetin on abscission in *Phaseolus* explants are, like those of auxins, mediated through a control of senescence processes, and are dependent on the content of kinetin in the cells of the abscission zone, compared with those in other parts of the segment When kinetin is applied directly to the zone in lanolin, and the local concentration is presumably relatively high, this region may act as a locus of accumulation and also of high synthetic activity, with the result that senescence and abscission are retarded If kinetin is supplied elsewhere to the explant, then the cells of the zone become depleted of essential metabolites and undergo a premature senescence which results in accelerated abscission

We wish to thank Prof G E Blackman for his interest and encouragement

INDUCED TEMPERATURE TOLERANCE OF PLANT TISSUE *IN VITRO*

By PROF. C. A SCHROEDER

University of California, Los Angeles

THE concept of temperature lesions in plant tissues which may be corrected by exogenous metabolites of several types[1] suggests that heat tolerance of such tissues might be increased by appropriate manipulation of the environment During a series of investigations of the effects of temperature on tissue explants from avocado fruit pericarp grown under sterile conditions on agar media[2], it was noted that survival to extremely high temperatures could be induced with appropriate preconditioning treatment Empirical observations indicated that tissue taken from firm, mature fruit will tolerate a temperature of 50° C for 10 min with no apparent impairment of subsequent growth potential whereas exposure to 55° C for 10 min resulted in killing of the tissues Incubation of tissue at 25° C allows for optimum growth of the segments by cell proliferation If the tissue was pretreated by exposure to 50° C for 10 min, incubated at 25° C for 3 days and then subjected to 55° C for 10 min and again incubated at 25° C for a period of 4 weeks, there appears to be survival of the pretreated tissues whereas nonpretreated control tissue fails to grow when similarly exposed Survival and subsequent growth in this case are determined by evidence of mitotic activity which can be detected under the microscope and by increase in fresh and dry weight following a standard 4-week final incubation period

The basic technique involved is that used for tissue culture under sterile conditions[3] Six-dram screw cap vials are used, each containing 10 ml of Nitsch's[4] media in which Geigy-138 iron-chelate is substituted for the iron citrate and with the addition of 10 p p m of indolyl-3-acetic acid Pericarp disks 2 mm thick and 8 mm diam are prepared from fresh, firm fruits under sterile conditions The disks are placed on the nutrient agar in the vials which are then immersed in a temperature-controlled water bath for appropriate periods Incubation is accomplished in temperature-controlled cabinets at 25° C Mitotic activity is observed in those sections which survive and show growth.

A recent review of responses of plant materials and bacteria to high temperatures[5] indicates that this behaviour can be explained on the basis of differential reaction rates of synchronous metabolic systems competing for substrate materials at successively higher temperatures resulting in a condition of 'temperature unbalance' Conditioning of a tissue by thermal shock could inactivate heat-sensitive enzyme systems allowing the more heat-labile enzymes to build up products or by-products which can then be made readily available for further reactions at higher temperatures The results in Fig. 1 indicate a progressive increase in survival percentage of individual tissue disks with increase in time following initial pretreatment Thus in the work recorded here a maximum protective response is attained approximately two or three days following initial sub-lethal exposure This high-level survival response is maintained for a period of two or three days and is again lost as the pretreated tissue develops a state of equilibrium and afterwards begins a period of mitotic activity Control tissues untreated by thermal shock show positive evidence of mitotic activity well under way three days after planting on agar nutrient media The non-pretreated control tissues in active mitotic condition are killed on exposure to high temperature at the 3-day period and show no further growth Pretreated tissues tested under comparable conditions (55° C, 10 min) 3 days after pretreatment show mitotic activity and growth at the termination of the final incubation period

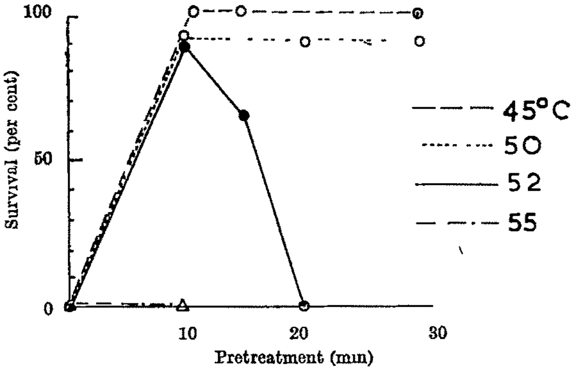

Fig 1 Survival of avocado pericarp tissue to high temperature (55° C) *in vitro* in response to pretreatment temperatures

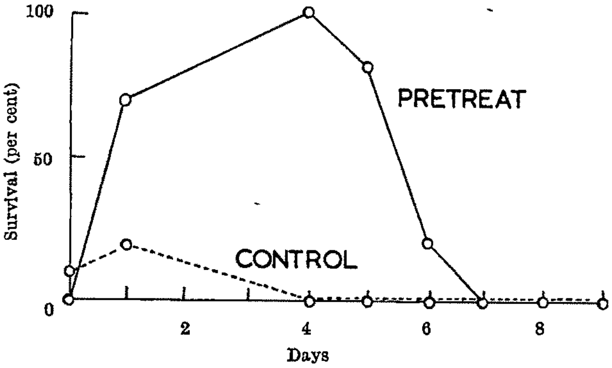

Fig 2 Survival of avocado pericarp tissue (at 55° C) in relation to time (in days) following pretreatment at 50° C Control not pretreated

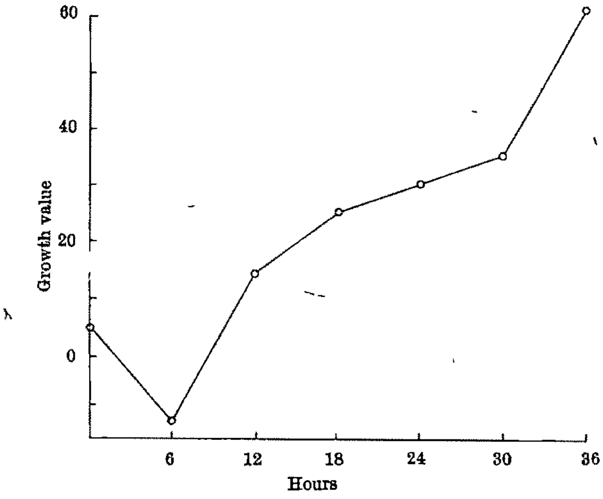

Fig 3 Growth value (difference between initial and final weights) of pretreated avocado pericarp tissue disks *in vitro* exposed to 55° C at various times (h) following pretreatment at 50° C

Pretreatment at 45°, 50° and 52° for 10 min respectively (Fig 1) provides essentially equal conditioning of tissue for subsequent high-temperature exposure, but as pretreatment temperature time is increased, there is apparent injury to the tissue and a failure to survive at the longer pretreatment exposures of 20 min at 52° C Some preliminary experiments have suggested that exposure time of 2–3 min at 50° C can provide sufficient thermal shock for the tissue to tolerate the standard test of 55° C, 10 min after 3 days' incubation

The thermal shock response is depicted in Fig. 3 in which the growth value (difference between initial and final weights) of pretreated disks minus the growth value of control disks is plotted against time (in hours) after pretreatment at which high-temperature test exposure is made These results suggest an accumulation of a substance or the development of a condition which provides protection against extreme temperature This condition reaches a maximum about 4 days after pretreatment and then declines in effectiveness (Fig 2).

The relationship between auxins and other exogenous materials to the alteration of protein coagulability as affected by heat has been demonstrated by Galston *et al* [6]. The several theories concerned primarily with protein and other organic molecules and their relationship with heat and cold tolerance of intact leaf segments to heat have been demonstrated[8]

It appears that the phenomenon of heat tolerance can be induced in plant tissue *in vivo* and *in vitro* and that tentative explanations are available concerning this response[7] The use of tissue culture techniques appears to offer a refined approach to the testing of the phenomenon and to aid in possible analysis concerning some of the biochemical reactions which may be involved

LETTERS TO THE EDITOR

PHYSICS

Observations of the *Zeta* Spectrum in the Wave-length Range 16 Å–400 Å

SPECTROSCOPIC studies of *Zeta*[1] are now being carried out in the important wave-length region below 400 Å. Previous investigations in the vacuum ultra-violet have been mainly confined to the region between 400 Å and 2000 Å using a variety of vacuum grating spectrometers with both photographic and photoelectric detectors. Thus, spectral line identifications have been made by Butt *et al.*[1], and Fawcett *et al.*[2]. Measurement and interpretation of the temporal variation of spectral line intensities have been made by Burton and Wilson[3], and Hobbs *et al.*[4], and measurement of the Doppler profiles of spectral lines has been made by Jones and Wilson[5]. More recently, observations have been made by Heroux[6,7], who measured the relative intensities of spectral lines in order to determine the electron temperature, using a grazing incidence rocket monochromator[8].

Recent observations using grazing incidence spectrometers designed and built at Culham have extended the range of measurement down to 16 Å, and it is the purpose of this letter to give an early survey of these results. Two instruments were used in this work. The first is a 1-m instrument[9] with both photographic and photoelectric recording, using a 1,080 line/mm original grating ruled at the Nobel Institute, Stockholm, and operated at 5° grazing angle. This is a laboratory instrument designed to examine high-temperature plasmas, and has been used for the photoelectric studies and for accurate wave-length calibration of strong lines in higher orders. The second is a rocket instrument with photographic recording designed to study the solar spectrum from above the atmosphere. It has a Bausch and Lomb 600-line/mm blazed replica grating of 1 metre radius, and can operate at grazing angles between 1° and 4°. Fitted with a vacuum tank it has been used on *Zeta* for photographic survey work and has recorded the *Zeta* spectra reproduced in this letter.

For most of this work the *Zeta* discharge was operated in deuterium or hydrogen at a pressure of 0·5 m torr, sometimes with a small addition of other gases. The electron temperature was not measured during these observations, but can be inferred from the work of Heroux[7] to vary in the range 20 eV–40 eV. Two spectral ranges are of particular interest and have been selected for discussion.

(*a*) 16 Å–50 Å. This region contains the important resonance lines of the common impurity elements carbon, nitrogen and oxygen in their helium-like and hydrogen-like ionic species. These are shown in a section of *Zeta* spectrum reproduced in Fig. 1. This was obtained with a 1° grazing angle and recorded on Kodak *S.W.R.* film. The filling gas was deuterium at 0·5 m torr pressure to which 2 per cent of air and a trace of argon were added. The gas current reached a peak of 630 k.amp, and an axial stabilizing magnetic field of 1,040 gauss was applied. Identification of the stronger lines is indicated in Fig. 1 and details are listed in Table 1. The shortest wave-length so far observed is at 16·0 Å and is tentatively identified as the Lyman β line of OVIII.

(*b*) 170 Å–212 Å. Above 50 Å the spectral lines are generally formed by more complex systems but identifications are proceeding satisfactorily. An important exception occurs in the wave-length range 170 Å–212 Å. A very intense system of lines occurs in this region, the wave-lengths of which do not coincide with any known lines. A group of intense lines is also present in this region of the solar spectrum as observed by Tousey *et al.*[10], Behring *et al.*[11], and Hinteregger[12], and these lines also remain unidentified. The *Zeta* spectrum in this region is reproduced in Fig. 2, together with the solar spectrum of Tousey *et al.*[10]. The wave-lengths of the more intense *Zeta* lines have been measured in the fourth and fifth order using first order neon reference lines[2,13,14] and the weaker members in the first order using oxygen standards[15]. These wave-lengths and their approximate relative intensities have been listed in Table 2 together with the wave-lengths and relative intensities of some of the solar lines. The latter have been derived by Allen[16] from published[10–12] and circulated data.

Sun *Zeta*

Fig. 2

It is clear from Fig. 2 and Table 2 that, with a few exceptions (notably the solar line at 201·9 Å), these lines match in wave-length within the errors of measurement and have similar relative intensities. There can be little doubt that many of these lines arise from the same transitions in the two sources. This is of some importance since the production of the lines in the laboratory strengthens considerably the chances of identification.

These lines from *Zeta* cannot be identified as being due to known impurities present or introduced in the filling gas, that is, carbon, nitrogen, oxygen, neon and argon, as the addition of controlled quantities of these elements failed to produce the expected changes in their intensities. Furthermore, the lines are still present when the discharge is operated in a mixture of neon and argon (that is, without hydrogen present). Photoelectric studies of these lines showed that their peak intensity is reached at the time of peak current and increases with increasing current and with decreasing stabilizing magnetic field. These observations are consistent with the unknown lines being due to material liberated from the surface of the stainless steel wall during the discharge-cycle. Work to extend the identification of the *Zeta* spectrum is proceeding and includes investigation of the unknown lines between 170 Å and 212 Å.

Table 2. Unidentified Lines between 170 Å and 212 Å

This work represents the initial phase of a general programme at Culham Laboratory to develop grazing incidence techniques for the study of high-temperature plasmas. This includes launching the rocket spectrograph described, together with a number of other instruments designed to investigate solar radiation, in the first British stabilized rocket during the coming year.

We thank several colleagues for valuable assistance, Mr. R. S. Pease for useful discussions, and Dr. R. Tousey for permission to reproduce a print of his solar spectrum. Finally, we thank Prof. C. W. Allen for valuable advice and for providing us with his data on the solar spectrum.

Magnetic Effects in the Far Infra-red Spectrum of Nitrogen Dioxide (NO_2)

In this communication we report the first observation of magnetic splittings in the far infra-red spectrum of a simple molecule. These effects can be predicted qualitatively from the free radical nature of the molecule and quantitatively from the analysis of the microwave spectrum[1]. An earlier search in this region[2] failed to exhibit these effects, due to lack of adequate resolving power. With the attainment of resolution of 0·10 cm^{-1} by interferometric methods[3], the phenomenon can now be observed.

The magnetic interactions which produce the splittings observed in the spectrum of nitrogen dioxide (NO_2) involve a coupling of the odd electron spin to the magnetic moment generated by rotation of the molecule. The principal term involved is the indirect coupling term, which can be treated as a mixing of the excited electronic states of the molecule with the $^2\Sigma$ ground-state. This coupling has been treated by several authors, and Curl and Kinsey[4] have reduced all these treatments to a common basis. Lin's formulation of the theory is the most convenient for

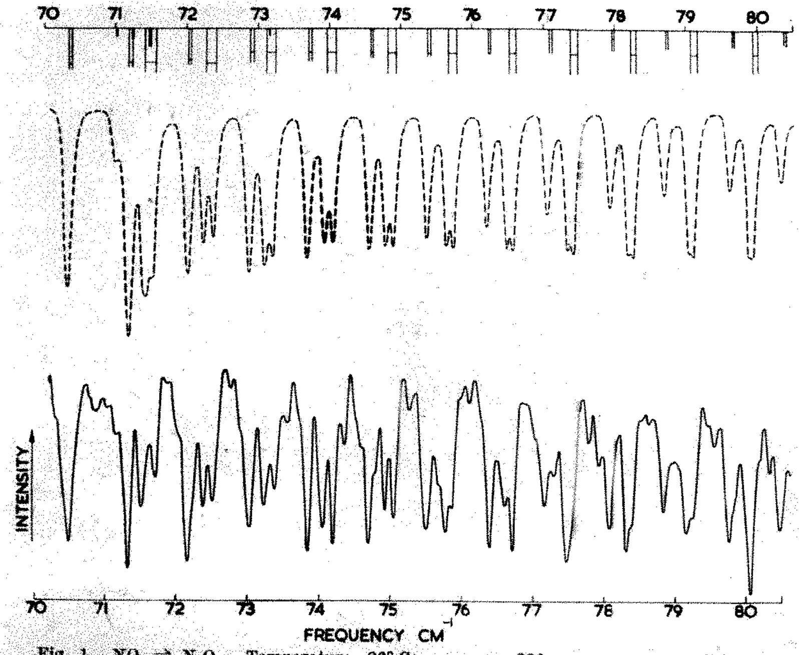

Fig. 1. $NO_2 \rightleftharpoons N_2O_4$. Temperature, 26° C; pressure, 226 mm mercury; cell-length, 44 cm; resolution, 0·1 cm^{-1}

the present problem[5]. This theory has been extended to the case of finite asymmetry[6]; but the symmetric top approximation ($b_p = 0$) is adequate for present purposes. The complete equations for the energies of the two magnetic levels $J = N + \frac{1}{2}$ and $J = N - \frac{1}{2}$ are given by equations (1*a*) and (1*b*), with the coupling constants shown in equation (2):

$$W(N, K_{-1}K_{+1}, J = N + \tfrac{1}{2}) = W^\circ(N, K_{-1}K_{+1}) + \frac{N}{2}\,\varkappa_{NK}$$

$$W(N, K_{-1}K_{+1}, J = N - \tfrac{1}{2}) = W^\circ(N, K_{-1}K_{+1}) - \frac{(N+1)}{2}\,\varkappa_{NK} \qquad (1a)$$

$$\varkappa_{NK} = \left[\frac{\varepsilon_B + \varepsilon_C}{2}\right] + \frac{K_{-1}{}^2}{N(N+1)}\left[\varepsilon_A - \frac{\varepsilon_B + \varepsilon_C}{2}\right] + \left\{\frac{(-1)^N}{4}\,\delta_{1K_{-1}} - \frac{b_p F^2(N, K+2)}{16N(N+1)(K+1)} + \frac{b_p F^2(N, K-2)}{16N(N+1)(K-1)}\right\}[\varepsilon_B - \varepsilon_C] \qquad (1b)$$

where: N, K_{-1}, K_{+1} are the usual asymmetric top quantum numbers:

$J = N \pm \frac{1}{2}$ is the sum of electron spin plus rotational angular momentum

ε_i is the spin-rotation coupling constant for rotation, about the i_{th} axis.

$\varkappa_{NK}$ is simply a convenient intermediate computational term, constant for a given rotational state.

$\delta_{1K_{-1}} = 1$ when $K_{-1} = 1$, 0, otherwise

$$b_p = \frac{C - B}{2\left[A - \dfrac{B+C}{2}\right]}$$: the Wang asymmetry parameter.

$$F^2(N, K \pm 2) = \{N(N+1) - K(K \pm 1)\}\,\{N(N+1) - (K \pm 1)(K \pm 2)\}$$

This term vanishes for $F^2(N, 1)$, $F^2(N, 0)$ and for $F^2(N, 2)$ associated with the state $N_{2,N-1}$:

$$\varepsilon_A = 2\zeta A \sum_l \frac{|(O|L_A|l)|^2}{E_0 - E_l} + a_A \qquad (2)$$

ζ = spin-orbit coupling constant.

A = reciprocal moment of inertia.

l = summation over excited electronic states.

$|0(|L_A|)|^2$ = squared transition element to excited state l.

a_A = direct-coupling term usually $\ll \varepsilon_A$.

It is found in the microwave analysis that the *B*- and *C*-axis coupling constants are relatively small, and may be ignored in treating the far infra-red data at this level of resolution, except for levels with $K_{-1} = 1$.

Some early interferometric spectra of NO_2 were taken while the microwave analysis was still in progress, but the present spectra at high resolution were not obtained until the microwave analysis was substantially complete. A theoretical spectrum was calculated from the preliminary microwave parameters as shown in Table 1, using Dr. R. H. Schwendeman's values of calculated Wang expansion coefficients for the energies of a slightly asymmetric top to 5th order in asymmetry. The rotational transitions were calculated on the IBM 7090 computer at the Massachusetts Institute of Technology, and the output cards from this programme were then carried through a simple splitting programme to give the final spectrum complete with relative intensities. A contour matching the observed spectrum in resolution has been produced from the theoretical results and compared directly with the observed spectrum as shown in Fig. 1. Magnetic effects are present throughout the spectrum, but in most cases the well-split lines are overlapped by other strong lines. The region 70–80 cm^{-1} happens to be free of this sort of overlap, and the regular progression of doublets is a set of related lines showing splitting greater than 0·10 cm^{-1}. In Fig. 1, the theoretical profile has been displaced towards high frequency by 0·1 cm^{-1}, to match the observed curve. Otherwise the observed curve is in agreement with the predictions from the microwave spectrum.

Table 1. MICROWAVE PARAMETERS OF NO_2*

$\frac{B+C}{2}$ = 0·422004 cm^{-1}

$A - \frac{B+C}{2}$ = 7·578805 cm^{-1}

b_p = − 0·001532786

D_J = 2·795 × 10^{-7} cm^{-1}

D_{JK} = − 1·910 × 10^{-5} cm^{-1}

$\varepsilon_A(1)$ = + 0·1518 cm^{-1}

D_K = 2·532 × 10^{-3} cm^{-1}

* A more refined set of parameters will appear in ref. 1; differences from the present set will have trivial effects on the far infra-red spectrum. Centrifugal distortion has been calculated on a symmetrical top basis—a procedure adequate except for K = 0, 1, 2.

$\varepsilon_A(1)$ is the *a*-axis spin rotation parameter obtained from first-order calculation. The more accurate value derived from second-order corrections is $\varepsilon_A(2) = 0{\cdot}1804_4$ cm^{-1}. The calculations given here are consistent with the use of $\varepsilon_A(1)$.

There is one very important distinction between a microwave spectrum and a high-resolution far infra-red spectrum, and this lies in the ease of analysis. In the microwave region one sees data which are at once too detailed and too narrowly selected from the entire rotational spectrum. Possession of the far infra-red spectrum allows one to look first at broad patterns and to proceed smoothly through increasing degrees of complexity in the analysis. Two of the writers of this paper have been concerned with both types of spectra and can state from experience that the ratio of times expended in analysing spectra in these two regions is about one month of work in the microwave spectrum per hour of work in the far infra-red. Whenever the spectrum of some new polyatomic free radical is obtained in both the microwave and far infra-red regions, we would predict that the analysis will proceed most easily through initial treatment of the far infra-red spectrum followed by detailed analysis of the microwave spectrum.

Sedimentation of a Large Number of Particles as a Cluster in Air

IN an attempt to explain the distribution produced on the ground by the sedimentation of particles from an "instantaneous point source" under the influence of the wind, Davies[1] assumed that the particles fell with their Stokes velocity and had no influence on the rate of fall of neighbouring particles. The complicating factors of the differing settling velocities, resulting from an extended range of particle sizes, and turbulent diffusion, from the influence of the wind, make it difficult to test this assumption under his experimental conditions. It would, however, be remarkable if particles did not affect each other when falling through air as a cluster, as they do in other fluids[2].

An examination has been made of the sedimentation of clusters 25–90 cm diameter, composed of small spherical particles of glass and also of 'Diakon', through still air. In each case the particles were exhaustively sieved through sieves which complied with B.S.S. 410 and dispersed as a roughly spherical cluster, the initial distribution along the horizontal axes being Gaussian. An attempt was made to obtain a Gaussian distribution vertically, but this was abandoned when it was found that the behaviour of the cluster was independent of the distribution of the particles for a given size of cloud. Three different types of behaviour have been observed all of which indicate mutual interference in the sedimentation of the particles. In all cases the rate of fall of the cluster exceeded the terminal velocity of the individual particles.

With 'Diakon' particles less than 64μ diameter, clusters approximately 50 cm diameter which contained approximately 2 g of material fell initially as roughly spherical vortices with vertical axes. The circulation of the particles in these clusters was downwards in the centre. This observation was in accord with the behaviour of suspensions in liquids and similar, though of opposite sense, to the rise of masses of hot moist air to form cumulus clouds[3].

When the particles were larger (>150μ) the behaviour of the cluster changed. Immediately on release a circulation of the same nature as above was set up; this was transient and the particles became distributed in the form of a bowl (Fig. 1). These bowl-shaped clusters were formed in all cases when the terminal velocity of the individual particles was greater than about a third of that of the sedimentation rate of the cluster as a whole. It would appear that this distribution of particles resulted from the inability of the individuals to rise at the edges of the vortex at a sufficient velocity to maintain the vortex.

When the weight of material dispersed was increased the cluster fell in a turbulent manner. The mass at which turbulent behaviour set in increased with increasing particle size and increasing density of the disperse phase.

GEOPHYSICS

A Solar Anisotropy in Cosmic Radiation, viewed from a Terrestrial Frame of Reference

IT is generally recognized that a solar anisotropy in the primary cosmic radiation must be responsible for at least part of the observed terrestrial daily variation of intensity, although it seems that the exact nature of this contribution is not yet clear. However, Rao, McCracken and Venkatesan[1] have recently presented a method of determining the characteristics of a daily variation of this type. Their method takes into consideration the influence of the Earth's magnetic field and in particular they emphasize the part played by the asymptotic cones of acceptance of cosmic ray detectors. Consequently, using experimental values of the daily variation of neutron intensity averaged over the year 1958, they have been able to postulate a type of anisotropy which appears to account for the complex manner in which the amplitude and phase of the first harmonic of the daily variation depends on the geographical location of the detector. However, it would perhaps be truer to say that they predict that if the Earth's atmosphere and its magnetic field were removed the annual mean diurnal variation of intensity observed at the Earth's surface would have the following characteristics: (1) the diurnal variation would be independent of rigidity in the range 1–200 GV, (2) the amplitude would vary as the cosine of geographic latitude and the time of maximum would be in the direction 85° to the east of the Earth–Sun line, (3) the maximum amplitude, observed with narrow-angle detectors at the equator, would be 0 4 per cent of the average primary flux It is proposed to describe here the co-ordinate transformations which relate these important characteristics to those of a solar anisotropy specified in the frame of reference in which its orientation is fixed

Following Rao *et al*, let us suppose that the intensity anisotropy is fixed in the co-ordinate system the reference planes of which are the ecliptic and the plane normal to it through the Earth–Sun line In this framework let us specify the anisotropic component of the total intensity as $AI_0(R) \cos \Lambda \cos (\psi - \psi_0)$, where A is the amplitude constant, $I_0(R)$, the average cosmic ray differential rigidity spectrum, Λ, the ecliptic latitude of the detector, and ψ, its direction of viewing in the plane of the ecliptic, measured eastward of the Earth–Sun line, with ψ_0 the direction of maximum intensity In what follows it will be more convenient to refer the direction of viewing in the plane of the ecliptic to the direction of maximum intensity and express it as $\psi - \psi_0$ We now have to transform to the terrestrial co-ordinate system the reference planes of which are the equator and the plane normal to it through the Earth–Sun line

Transforming first to the conventional ecliptic system, specified by the plane of the ecliptic and the equinox, the spherical co-ordinates of the direction of viewing become Λ and $\lambda_a + \psi - \psi_0$, where λ_a is the ecliptic longitude in the direction of maximum intensity The corresponding co-ordinates in the terrestrial equatorial system, specified by the equator and the equinox, are the geographic declination δ and the right ascension $\alpha_a + \varphi - \varphi_0$, where α_a is the right ascension of the direction of maximum intensity and $\varphi - \varphi_0$ are the directions of viewing and of maximum intensity in the plane of the equator, both measured eastward of the Earth–Sun line We can now transform simply from one set of co-ordinates to the other by rotation of the axes of one of the co-ordinate systems through the angle ε without change of origin, ε being the obliquity of the ecliptic Projections on the appropriate axes yield

$$\cos \Lambda \cos (\lambda_a + \psi - \psi_0) = \cos \delta \cos (\alpha_a + \varphi - \varphi_0) \tag{1}$$

and

$$\cos \Lambda \sin (\lambda_a + \psi - \psi_0) = \cos \delta \sin (\alpha_a + \varphi - \varphi_0) + \sin \delta \sin \varepsilon \tag{2}$$

Since the maximum difference between ecliptic longitude λ_a and right ascension α_a never exceeds about 2 5 degrees (cf values for the Sun in the *Nautical Almanac*) α_a can be substituted for λ_a in equations 1 and 2 Expanding and combining equations 1 and 2 to eliminate $\sin \psi$, we obtain·

$$\begin{aligned}\cos \Lambda \cos (\psi - \psi_0) = {} & [1 - (1 - \cos \varepsilon) \sin^2 \alpha_a] \cos \delta \cos (\varphi - \varphi_0) \\ & - \frac{1 - \cos \varepsilon}{2} \cos \delta \sin 2\alpha_a \sin (\varphi - \varphi_0) \\ & + \sin \varepsilon \sin \delta \sin \alpha_a \end{aligned} \tag{3}$$

The right ascension of the anisotropy, α_a, is $\alpha_a = \alpha_s + \varphi_0$, where α_s is the Sun's right ascension We can replace φ_0 by ψ_0 since, like λ_a and α_a, the two constants never differ by more than about 2 5 degrees Therefore making these substitutions in equation 3 and multiplying through by $AI_0(R)$ we finally have

$$\begin{aligned} AI_0(R) \cos \Lambda \cos (\psi - \psi_0) = {} & AI_0(R) \{[1 - (1 - \cos \varepsilon) \sin^2 (\alpha_s + \psi_0)] \cos \delta \cos (\varphi - \psi_0) - \left(\frac{1 - \cos \varepsilon}{2}\right) \cos \delta \sin 2(\alpha_s + \psi_0) \sin \\ & (\varphi - \psi_0) + \sin \varepsilon \sin \delta \sin (\alpha_s + \psi_0)\} \qquad (4) \\ = {} & AI_0(R) \{[1 - 0\ 0826 \sin^2 (\alpha_s + \psi_0)] \cos \delta \cos (\varphi - \psi_0) \\ & - 0\ 0413 \cos \delta \sin 2 (\alpha_s + \psi_0) \sin (\varphi - \psi_0) \\ & + 0\ 3979 \sin \delta \sin (\alpha_s + \psi_0)\} \text{ for } \varepsilon = 23^\circ\ 27' \end{aligned}$$

On the right-hand side of equation 4 the anisotropic component of primary intensity is expressed as a function of geographic latitude, time of day relative to local noon, and day of the year as specified by α_s, which, for practical purposes, can be regarded as the right ascension of the Sun at transit at Greenwich The co-ordinates δ and φ refer, of course, to the asymptotic direction of viewing of a cosmic ray detector with respect to primaries of rigidity R

It may be of interest to mention an application of equation 4 to observations of the intensity of sunlight falling on unit area of the Earth's surface In this case, $\psi_0 = 0$ and the conditions for sunrise and sunset are that $\psi = \pm \pi/2$ The solutions for φ then give the approximate sundial times of sunrise and sunset at the latitude δ at the time of the year specified by α_s The co-ordinates δ and φ may be likened to asymptotic directions of viewing since the atmosphere, and therefore refraction, has been disregarded

We note that $AI_0(R) \cos \Lambda \cos (\psi - \psi_0)$ transforms to a solar diurnal variation and a total intensity term $AI_0(R) \sin \varepsilon \sin \delta \sin (\alpha_s + \psi_0)$ to which it reduces at the geographic poles That is to say, at the poles the anisotropy manifests itself as a small seasonal variation of the total intensity The expression for the diurnal variation at other latitudes allows the seasonal variations of amplitude and phase to be worked out For example, at the latitude of Hobart (43° S) these amount to a small semi-annual variation of amplitude, the maximum departure from the mean being less than 10 per cent, and an almost negligible (less than 5 degrees) semi-annual variation of phase Spurious sidereal and anti-sidereal effects are absent

The annual mean expression for the anisotropy is obtained by integrating equation 4 with respect to α_s, giving

$$\begin{aligned} AI_0(R) \cos \Lambda \cos (\psi - \psi_0) & = AI_0(R) \left(\frac{1 + \cos \varepsilon}{2}\right) \cos \delta \cos (\varphi - \psi_0) \\ & = 0\ 9587\ A \cos \delta \cos (\varphi - \psi_0) \text{ for } \varepsilon = 23^\circ\ 27' \end{aligned} \tag{5}$$

Therefore it happens that on the yearly average the anisotropy postulated by Rao *et al* would exhibit the same characteristics, except for a slight difference in amplitude, whether viewed from the terrestrial frame of reference or from that in which its orientation was fixed As might be expected a similar result would be obtained if the orientation were fixed in the plane of the Sun's equator instead of the plane of the ecliptic However, seasonal variations of amplitude and phase would be more pronounced and small apparent sidereal and anti-sidereal effects would be generated

If the latitude dependence differs from $\cos \Lambda$, the characteristics of a solar anisotropy may become greatly modified on transformation to the terrestrial frame of reference The cases $A \cos \psi$, $A \cos^2 \Lambda \cos \psi$, $A \cos^3 \Lambda \cos \psi$ and $A \cos^5 \Lambda \cos \psi$ will be discussed elsewhere Although transformation procedures for a simple type of sidereal anisotropy will also be mentioned a more detailed treatment may be found in a paper by L Davis[2]

In conclusion, it is hoped that the method outlined here may have indicated the need for correct transformations (*a*) when the characteristics of the anisotropy in its rest framework are to be deduced from the annual mean daily variation observed in the terrestrial frame of reference, after accounting for the influence of the atmosphere and the Earth's magnetic field, (*b*) when the day-by-day contributions which the specified anisotropy makes to the daily variation and to the total intensity of cosmic radiation in the terrestrial frame of reference are to be determined and the seasonal effects calculated

GEOLOGY

Dissolved Gases in East African Lakes

ACCORDING to the knowledge we have concerning the volcanic gases of Nyiragongo, the nearest volcano to the Lake Kivu of all the volcanoes of the Virunga Range, which constitutes the natural dam behind which Lake Kivu has formed, I cannot agree completely with Dr Kevin Burke's and Prof G Mueller's views regarding the origin of the dissolved gases of this Lake (*Nature*, 198, 568, 1963)

In 1959, we were able to collect gases close to, and even on, the permanent lava lake of Nyiragongo volcano[1] The sampling conditions were exceptionally good, in fact the best available so far with similar ones encountered by Shepherd[2] and Jaggar[3] in 1919 at the Halemaumau lava lake of Kilauea (Hawaii) Our own analyses, like those of Shepherd, showed no trace of methane But all of them disclosed relatively high contents of unoxidized gases carbon monoxide (average amount) 1 7 per cent of the 'active gases' (other than water, nitrogen + argon, oxygen) at Kilauea, 5 2 per cent at Nyiragongo and hydrogen (1 9 per cent for both Kilauea and Nyiragongo), moreover, Kilauea had also a sulphur content attaining 3 6 per cent of the 'active gases'

The nitrogen/oxygen average ratio in our four best Nyiragongo analysis is 10/1 5, and the nitrogen content (1 65–14 5 per cent) is quite different from that which should be expected should atmospheric oxygen have been consumed in oxidation of methane It seems difficult to accept the idea of all 'juvenile' methane having been oxidized prior to its escaping from vents situated very close to the molten lava lakes, while sulphur, carbon monoxide and hydrogen, on the contrary, are still present in significant proportions

On the other hand, methane has been found only in those volcanic gases—collected relatively far from the molten lava—on volcanoes situated in a geologically quite different situation, namely, in orogenic belts: Ambrym volcano (New Hebrides)[4], Guadeloupe[5], Santorin[6], Novarupta and the Valley of Ten Thousand Smokes[7], Kliuchevskii[8], Bezymiannyi[9], Asama Yama[10], etc

The analyses of the occluded gases in the lava (melilite basanite) of Nyiragongo[11] show no methane but 23 per cent carbon monoxide and 13 per cent hydrogen for 60 per cent carbon dioxide and 4 per cent nitrogen. This very high content of unoxidized gases (36 per cent), the low content of nitrogen (4 per cent) and the total absence of methane, all argue against a juvenile origin hypothesis of methane in the waters of the close-by Lake Kivu On the contrary, methane has been found occluded in the lavas from orogenic belts Tuscany ignimbrites[12], Mont Pelée (Martinique)[13], Novarupta[14]

All these facts show, I think, that the absence of methane in the volcanic gases of Nyiragongo is original, and is not due to atmospheric oxidation

Therefore, the high methane content of Lake Kivu should not be attributed to volcanism, and most probably, as Kufferath and Schmitz have supposed, is of biogenic origin; while carbon dioxide, the main constituent of the Nyiragongo 'active gases', would be of a juvenile origin

[14] Chaigneau, M , and Bordet, P , *C R Acad Sci* , *Paris*, **256**, 3167 (1963)

TAZIEFF's conclusion that the presence of substantial amounts of carbon monoxide and hydrogen in gas from Nyiragongo rules out the possibility of juvenile methane existing at depth is not justified since oxidation of methane by steam according to the reaction $CH_4 + H_2O = CO + 3H_2$ would yield just the gases that appear in his analyses This reaction has been investigated at one atmosphere[1,2] at which pressure equilibrium lies well to the right My library facilities are limited and I have been unable to find an account of variation with pressure, but clearly high pressure will shift the equilibrium towards the left Oxidation of methane by steam is not, of course, atmospheric oxidation and I regret the omission of a reference to alternative means of oxidation in my original communication

If methane is a widespread constituent of magmatic gas at depth its occurrence in surface gas from orogenic belt volcanoes may be correlated with their generally explosive character Slow upwelling of lava, as at Kilauea and Nyiragongo, might permit complete oxidation of methane by steam while rapidly rising gas, characteristic of the orogenic belts, might not be completely oxidized

I regard the nitrogen content of volcanic gas from a lava lake as of limited value in assessing the extent of atmospheric oxidation because oxygen can be added to the magma without nitrogen through reaction on the lake surface and subsequent reduction of oxidized material carried downward by convection

A final answer to the question of origin cannot be given until more complete analyses (and especially isotopic analyses) of the Lake Kivu gas are available for comparison with the excellent results obtained for gas from Nyiragongo by Tazieff and his colleagues

Primary and Secondary Arcs in the Scandinavian Caledonian Chain

PROF J TUZO WILSON *et al* [1] have given an outline of the European Caledonian and Hercynian mountains Regarding the Scandinavian Caledonian chain these authors mention that secondary arcs can readily be made out in Sweden, and that igneous rocks of primary arcs are exposed in the Lofoten Islands off Norway

I agree that secondary arcs can be made out in Sweden With regard to the Lofoten Islands, rhenium/osmium determinations of molybdenites from these Islands gave the pre-Caledonian ages 2080 and 2290 million years[2] According to my investigations other Norwegian coast districts form parts of primary arcs

The Scandinavian Caledonian chain became inactive tectonically in Devonian time The chain is now weathered down, and parts of it are beneath the sea We can, however, still trace a narrow mountain system[3] (Fig. 1) The primary arcs lie through the following Norwegian counties Møre and Romsdal, Nordland, and Troms The arcs are now exposed as Caledonian gneisses and schists

The junctions of these arcs at which secondary arcs formed are in central and in northern Scandinavia The secondary arcs consist of two parts, an uplifted massif or

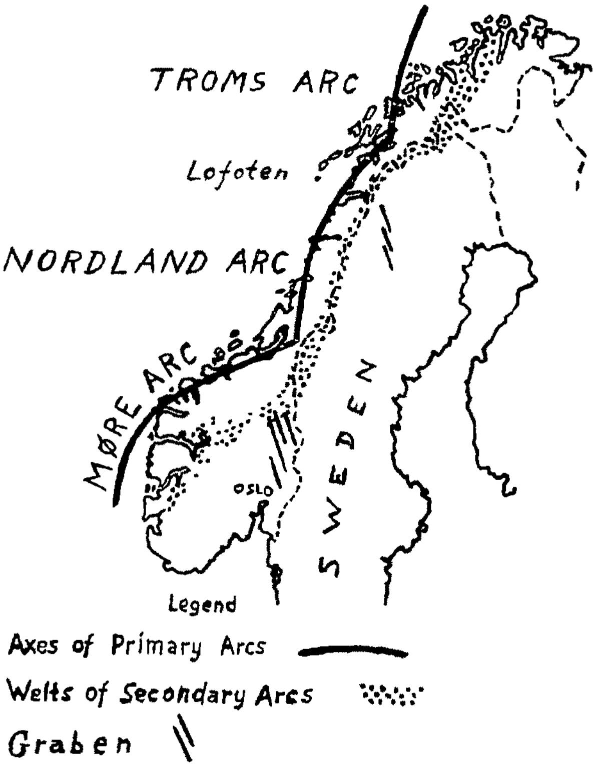

Fig. 1. The Scandinavian Caledonian chain, an inactive narrow mountain system

welt of the Precambrian basement, and, further from the primary arcs, a basin with thrust and folded Caledonian sediments. For example, the south Norwegian sparagmite region, with the Precambrian basement exposed in windows, forms a part of the uplifted massif, and the Oslo region is a preserved part of the corresponding basin of the southern secondary arc.

The graben corresponding to the southern secondary arc is exposed in the south Norwegian sparagmite region. Drilling has shown evidence of a buried graben[4], which corresponds to the northern secondary arc.

METALLURGY

Uhlig Model of Oxidation Kinetics

IT is well known that a space charge region is usually present in semiconducting oxides at metal-semiconductor junctions due to equalizing of Fermi levels at the junction[1]. Uhlig[2] has pointed out that this space charge layer may be a determining factor for growth rate and for growth law. Specifically, Uhlig proposes that the space charge layer limits the flow of electrons (and thus the flow of ions) from metal to oxide, so the variation of the space charge layer characteristics with film thickness determines the growth law. The purpose of this communication is to point out some basic errors in the treatment of the model so that further development of this approach, as well as comparison with new experimental results, can be fruitful.

The first objection to the treatment of Uhlig (see equation (5), ref. 2) is the misinterpretation of the position co-ordinate x for the total film thickness $y(t)$ in Poisson's equation. This leads to the application of physically meaningless boundary conditions, because the conditions are imposed for certain values of $y(t)$ [$y(t) = 0$ and $y(t) = l$] corresponding to certain fixed points in time, instead of for certain values of x [for example, $x = 0$ and $x = y(t)$] which hold for all time. In particular, the Uhlig treatment leads to a non-conservation of electrical charge during growth, provided the surface charge is constant at the air-oxide interface as claimed[2]. The predicted effects of space charge on rate are enhanced enormously for growth of thin films, since the parameter l denoting the extent of the space charge region in very thick films thus is introduced into the equations for growth of very thin films.

The second objection is the reduction of the metal-oxide work function by the electron affinity of oxygen adsorbed on the oxide even when the oxide film thickness is greater than the maximum distance which the electron can penetrate into the oxide from the metal crystal in a one-step process (for example, tunnelling or field emission into the oxide). We therefore offer the following modified derivation of the logarithmic law based on the same model.

An integration of Poisson's equation

$$\frac{d^2V}{dx^2} = -\frac{4\pi ne}{\varepsilon} \qquad (1)$$

for a constant density $n = n_0$ of trapped electrons of charge $e = -|e|$ gives

$$\frac{dV}{dx} = -E(0) + \frac{4\pi n_0|e|}{\varepsilon}x \qquad (2)$$

where $V(x)$ is the electrical potential, x is the position co-ordinate in the oxide normal to the metal surface with $x = 0$ being the metal-oxide interface, $E(0) = \frac{q\sigma}{\varepsilon}$ is the electrical field in the oxide at $x = 0$ due to the charged particle interfacial density, σ, at $x = 0$, q is the charge per particle at $x = 0$, and ε is the dielectric constant of the film. Further integration of equation (2) gives the electrical potential difference $[V(x) - V_0]$ from the interior of the metal to a point x in the film

$$V(x) - V_0 = -E(0)x + \frac{2\pi n_0|e|}{\varepsilon}x^2 \qquad (3)$$

The physically meaningful boundary conditions for the problem are constant electrical potential inside the metal, which can be designated as the zero of potential $[V_0 = 0]$ and over-all charge neutrality of the oxide-metal system. Any charged defects produced in the film induce an equal but opposite charge in the metal at $x = 0$. Thus for the case of zero surface charge density at $x = y(t)$, which is the outer surface of the oxide film

$$E(0) = \int_0^{y(t)} \frac{4\pi n_0|e|}{\varepsilon}\,dx = \frac{4\pi n_0|e|}{\varepsilon}y(t) \qquad (4)$$

and equation (3) reduces to

$$V(x) = -\frac{2\pi n_0|e|}{\varepsilon}[2y(t)x - x^2] \qquad (5)$$

Denoting by φ the Fermi-level E_0 of the neutral bulk oxide minus the Fermi-level E_m of the neutral metal, the total potential $\zeta(x)$ for an electron at position x in the oxide with respect to the interior of the metal is

$$\zeta(x) = \varphi - V(x) = \varphi + |V(x)| \qquad (6)$$

The injection of an electron from the metal into the oxide generally takes place against a potential barrier. The thickness of the barrier for thermionic emission is approximately one lattice constant a, but conceivably there could be thermal excitation to excited states with subsequent tunnelling through barriers of some greater thickness. We denote by δ the maximum tunnel thickness for the particular barrier $\zeta(x)$ given by equation (6) $[0 \leqslant x \leqslant \delta]$; this parameter δ must be computed or obtained experimentally for any given system, but is of the order of 50 Å If $y(t) < \delta$, then electrons can tunnel from the metal to adsorbed oxygen at the oxide–oxygen interface For this case, the activation energy ΔE for oxidation is given approximately by the difference in potentials at $x = 0$ and $x = y(t)$, minus K, where K is defined as the electron affinity of adsorbed oxygen on either the metal ($y(t) = 0$) or on the oxide ($y(t) > 0$) Using equations (5) and (6)

$$\Delta E = |e|\left[\varphi - K + \frac{2\pi n_0|e|}{\varepsilon} y(t)^2\right] \quad (y(t) < \delta) \qquad (7)$$

Since $y(t) < \delta$ for this case, the term in $y(t)^2$ is generally small compared with $\varphi - K$ (0 5–1 eV)^2 so long as $n_0 \ll 10^{18}/\text{cm}^3$, which we arbitrarily call the small space charge limit in this work For this limiting case

$$\Delta E \simeq |e|(\varphi - K) \qquad (8)$$

This is the same expression as the one suggested by Uhlig[2], although the present derivation is valid only in the small space charge limit and for film thicknesses $y(t)$ less than the maximum tunnel distance δ For $y(t) < \delta$ in the large space charge limit $[n_0 \geqslant 10^{18}/\text{cm}^3]$, equation (7) must be used to obtain ΔE

For $y(t) > \delta$, the parameter K cannot serve to aid the electron in its initial escape from the metal crystal, which is assumed to be the rate limiting step Equation (6) is then applicable, with x replaced by δ:

$$\Delta E = |e|\ \zeta(\delta) = |e|\left[\varphi + \frac{2\pi n_0|e|}{\varepsilon}\left\{2y(t)\delta - \delta^2\right\}\right] \quad (y(t) > \delta) \qquad (9)$$

For $y(t) \gg \delta$,

$$\Delta E \simeq |e|\left[\varphi + \frac{4\pi n_0|e|\delta}{\varepsilon} y(t)\right] \qquad (10)$$

Using an expression for the particle current J [note that $\mathrm{d}y(t)/\mathrm{d}t \propto J$] equivalent to that used by Uhlig[2]

$$J \propto e^{-\Delta E/kT} \qquad (11)$$

the following growth laws are obtained for the several limiting cases given above for ΔE

(*a*) for $y(t) < \delta$ and $n_0 \ll 10^{18}/\text{cm}^3$,

$$\frac{\mathrm{d}y(t)}{\mathrm{d}t} = A' \exp\left[-|e|(\varphi - K)/kT\right] \qquad (12)$$

(*b*) For $y(t) < \delta$ and $n_0 > 10^{18}/\text{cm}^3$,

$$\frac{\mathrm{d}y(t)}{\mathrm{d}t} = A' \exp\left[-|e|\left\{\varphi - K + \frac{2\pi n_0|e|}{\varepsilon} y(t)^2\right\}/kT\right] \qquad (13)$$

(*c*) For $y(t) \gg \delta$,

$$\frac{\mathrm{d}y(t)}{\mathrm{d}t} = A' \exp\left[-|e|\left\{\varphi + \frac{4\pi n_0|e|\delta}{\varepsilon} y(t)\right\}/kT\right] \qquad (14)$$

Thus the relation

$$y(t) = k_0 \log(1 + t/\tau) \qquad (15)$$

is obtained by integrating equation (14), where k_0 is given by $[\varepsilon kT/(4\pi n_0|e|^2\delta)]$ and τ is given by $(k_0/A')\exp(|e|\varphi/kT)$ Note from these results that for a given magnitude of space charge the value for k_0 is increased by ratio l/δ over that given in ref 2, where l represents some maximum width of the constant space charge region Since δ lies between 5 and about 50 Å, and $l \simeq 6 \times 10^{-4}$ cm, $l/\delta \simeq 10^3$ to 10^4 (Alternatively, this work requires an increase in the density of charged traps by this factor to give a certain value of k_0) Furthermore, in equation (14) the space charge term is competing with the large value φ compared with the much smaller value of $[\varphi - K]$ as given in ref 2, so that a change in rate is relatively slower to manifest itself in equation (14) In other words, the τ for equation (15) is found to be of the order of $(l/\delta)\exp\{|e|K/kT\}$ larger using equation (14) than is obtained in the work of ref 2 Since $K \simeq$ 3–4 eV, this factor is approximately exp (+100) (Alternatively, for a given τ these equations require a much smaller metal-oxide work function φ The φ must have a value of about 0 5–1 eV corresponding to the $(\varphi - K)$ in ref 2)

A linear growth law is obtained from equation (12), and a growth law with a sharper cut-off at the limiting thickness than the logarithmic law is obtained from equation (13) These two laws are not expected to be very important, however, because of the restriction to film thicknesses less than about 50 Å It should be mentioned that the Uhlig model does not provide for an electronic transport mechanism for $x > \delta$ In addition, ionic transport is totally ignored Thus some mechanism for easy ionic transport must be assumed in order to have any growth at all, and some easy electronic transport mechanism for $x > \delta$ must be assumed in order to obtain film thicknesses greater than δ

This work is not extended to the diffuse space charge layer[2] The case for any distribution of non-diffusing space charge can be treated in the above manner provided the expressions can be integrated An equilibrium distribution of charged defects, however, is the wrong basis for examining space charge effects in growing oxide films[3]

In summary, then, the correct use of Poisson's equation and the application of physically meaningful boundary conditions to the Uhlig space charge model for the logarithmic growth law has revealed that the predicted concentration of charged defects must be increased by a factor of 10^3–10^4 and the metal-oxide work function decreased by almost an order of magnitude to yield an appreciable effect on growth rate Thus a charged defect concentration greater than approximately $10^{18}/\text{cm}^3$, and a work function lower than about 0 5 eV are prerequisites for this model to be applicable to the growth of thin oxide films

Diffusion of Oxygen in Tungsten and some other Transition Metals

Stringer and Rosenfield[1] have recently calculated some activation energies for diffusion of oxygen in transition metals, which were not otherwise available One of these metals was tungsten In a plot of activation energy versus melting point of the solvent, the authors attempted to show that tungsten and other metals dissolving less than about 1 per cent oxygen lay on a straight line through the origin; while those metals dissolving more than about 1 per cent oxygen fell on a straight line, which did not pass through the origin and which had a small negative slope The line through the origin was supposed to be indicative of a normal lattice distortion mechanism and the other line an ionization mechanism

Diffusivity data for oxygen in tungsten are now available following an internal friction study[2] The experimental activation energy is observed in Fig 1 to fit the 'high-solubility' line of Stringer and Rosenfield Assuming that a real difference in diffusion mechanism does underlie the 'low-' and 'high-solubility' lines, the possibility of correlating the solubility with the mechanism now seems more remote

The 'high-solubility' line can be explained in the same terms of elastic strain as the line through the origin Zener's well-known theory of D_0 predicts a linear relation-

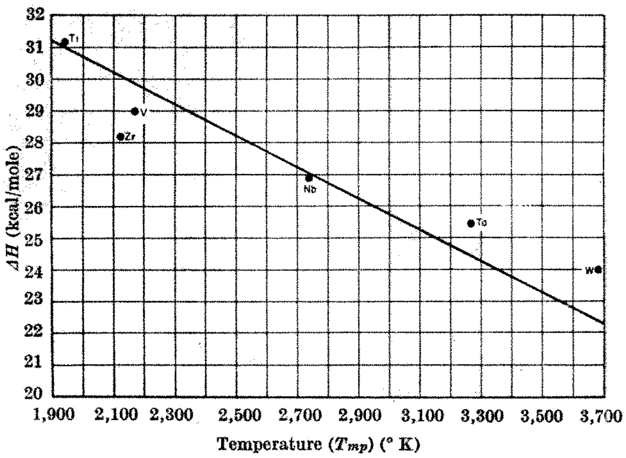

Fig. 1. Heat of activation for diffusion of oxygen in various transition metals having the melting points shown

ship between the energy of activation (ΔH) and the melting point of the solvent (T_{mp}) when:

$$T_{mp}\frac{\delta\left(\frac{\Delta S}{\beta}\right)}{\delta T_{mp}}+\frac{\Delta S}{\beta}=K$$

where ΔS is the entropy change, and β and K are constants. Since ΔS and β are always positive, a negative slope (that is, negative K) can only result when $\frac{\delta\left(\frac{\Delta S}{\beta}\right)}{\delta T_{mp}}$ is negative and $\left|T_{mp}\frac{\delta\left(\frac{\Delta S}{\beta}\right)}{\delta T_{mp}}\right|>\frac{\Delta S}{\beta}$. This condition is indeed met, as shown by the plot of theoretical $\Delta S/\beta$ versus T_{mp} in Fig. 2, and the good agreement with experimental points. The point for tungsten is the only one deviating to an appreciable extent from theory, and this is probably due to the instability of the internal friction peaks and a resultant high D_0. This instability would be expected to have a negligible effect on ΔH. Theoretical entropy changes were calculated from Zener's equation, $\Delta S = \beta\Delta H/T_{mp}$, using $\beta = 0{\cdot}4$ and the ΔH's listed in Table 1. The experimental values of ΔS were obtained from the formula, $D_0 = \gamma a_0^2 \nu \exp\frac{\Delta S}{R}$, using $\gamma = 1/6$, $\nu = 10^{13}$/sec and the lattice parameters (a_0) and D_0's appearing in Table 1.

Boron Constituents in Low-boron Steel

IT has been demonstrated by autoradiography that, in steel and related alloys containing boron, this element sometimes segregates to grain boundaries of the matrix. This has to be taken into account when considering the damaging effect of neutron irradiation, boron-10 capturing neutrons and emitting lithium and helium.

To determine the degree of boron enrichment by identifying possibly existent boron-containing phases, thin foils of a steel containing 0·0026 per cent boron have been examined by selected area electron diffraction. The material was austenitized at 1,110° C and isothermally transformed at 650° C for 1 h. This treatment is known to reveal the presence of particles of a particular boron constituent in the rim of ferrite which is formed along the austenite grain boundaries[1]. Such particles are shown in Fig. 1, which is a transmission electron micrograph of a thin foil steel specimen. When comparing the electron diffraction patterns obtained from these particles (Fig. 2) with known crystallographic data for conceivable boron-containing phases, correlation was found for Fe_2B and FeB.

This result is interesting both from the point of view of the application of such material in nuclear reactors, mentioned here, and as an advancement of the methods of detecting boron enrichment. Previously the necessary boron content in alloys in which segregation could be found, by autoradiography, was 0·005 per cent[2]. As to the exis-

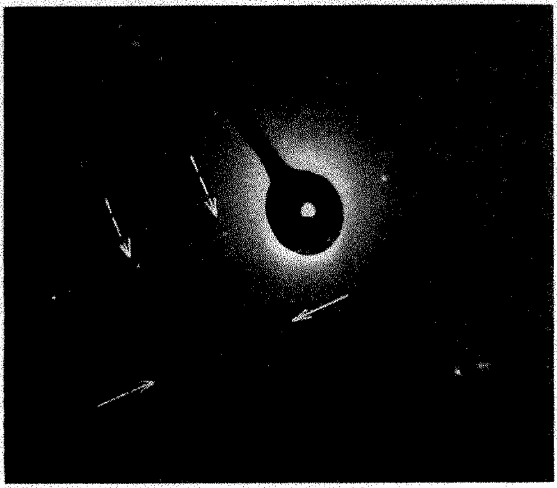

Fig. 2. Diffraction pattern of area containing Fe_2B (full arrows) and FeB (dashed arrows)

tence of FeB in addition to Fe_2B, this is not unexpected, since FeB has been found by electron microprobe analysis in a steel containing 0·1 per cent boron[3].

CRYSTALLOGRAPHY

Similarity of Octacalcium Phosphate and Hydroxyapatite Structures

THE formation of lamellar mixed crystals of hydroxyapatite and octacalcium phosphate have been postulated by Brown *et al.*[1] to account for 'defect apatites' and other properties of precipitated calcium phosphate salts. One of the mechanisms they suggested for the layering is that of epitaxial overgrowths, since some similarity of structure was recognized. The similarity which Brown[2] demonstrated, however, is not nearly so striking as the similarity that can be shown.

Brown recognized that both the hydroxyapatite and the octacalcium phosphate structures have alternating chains of calcium and phosphate along the *c* axis. Also, that octacalcium phosphate has part of a hexagon that is present in hydroxyapatite. Hydroxyapatite has flattened hexagons made of alternating calciums and phosphates around the hydroxyl positions. In advancing along the *c* axis of the crystal these hexagons are shifted 60° so that the projection of these on a single plane places the calciums and the phosphates in regular hexagons. The phosphate hexagons are slightly larger than the calcium hexagons. Brown showed that octacalcium phosphate has four of the six positions of each hexagon.

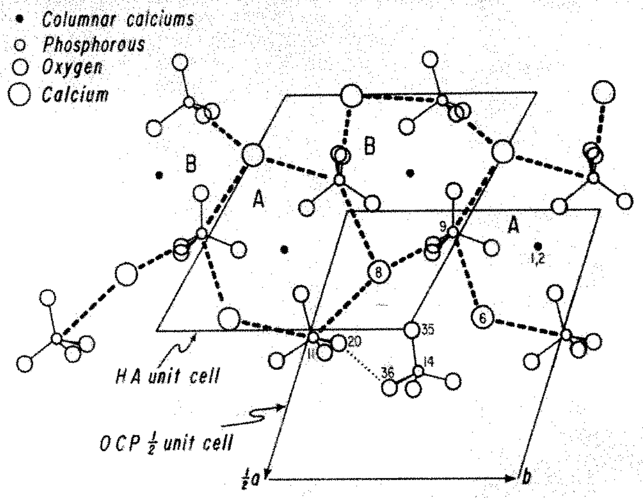

Fig. 1. Atomic positions in octacalcium phosphate for the plane *c* equal to approximately 0·25. The numbers given correspond to the numbering system used by Brown (ref. 2)

The more striking similarity is shown in Fig. 1. In this partial picture of octacalcium phosphate the complete hydroxyapatite structure can be seen except for the hydroxyls. The hydroxyl ions would be at the corners of the hydroxyapatite unit cell. In the case of octacalcium phosphate these positions are filled instead by water molecules (not shown) in the upper corners and by hydrogen phosphate in the lower corners (one shown, *P* number 14). Hexagons are formed around the axis of the columnar calciums such as around position 1, 2. There are two distinct types of hexagons: one quite regular (*A*) and the other distorted slightly (*B*). The distortion is due to shorter phosphorus to columnar calcium distances than the hexagonal calcium to columnar calcium distances. The two types alternate with each other along the '*c*' axis for both hydroxyapatite and octacalcium phosphate, that is, in the second plane of the unit cell in each crystal the positions of the two are reversed. More precisely, the second plane is the same as the first except for a 180° rotation of the hydroxyapatite unit cell content, including the water and hydrogen phosphate.

Table 1. COMPARISON OF DISTANCES IN HYDROXYAPATITE (HA) AND OCTACALCIUM PHOSPHATE (OCP)

Positions	Hydroxy-apatite	Octacalcium phosphate *
Columnar calcium to hexagonal calcium		
Regular hexagon	3·95	3·91 ± 0·06
Flattened hexagon	4·03	4·02 ± 0·08

Regular hexagon	3 +	3 +
Flattened hexagon	2·51	2·52 ± 0·06
Hexagonal calciums to oxygens		
Adjacent planes (usual chains)	2·37	2·36 ± 0·02
(exceptional chain)	—	2·24

* In each unit cell there are more than one of the described distance relationships. In hydroxyapatite these distances are essentially identical but in octacalcium phosphate they are quite variable, hence an average ± the standard deviation is given.

† The distances for octacalcium phosphate were calculated from the unit cell parameters given by Brown (ref. 2) and those for hydroxyapatite from those given by Posner *et al.* (ref. 3). These hydroxyapatite distances agree within 0·01 Å with those published by Posner except in the case marked with a dagger, where the difference is 0·03 Å.

Table 1 compares the dimensions of the two hexagons in the two structures. The two crystals are seen to contain almost identical hexagons. The distances in octacalcium phosphate are generally a few hundredths of an Å larger than in hydroxyapatite. The distances between calciums and phosphate are shorter in one of the chains along the *c* axis than the other 3 in a 1/2 unit cell of octacalcium phosphate or the 6 in hydroxyapatite.

This view of the two crystals suggests an explanation for the observation[1] that octacalcium phosphate grows more rapidly than hydroxyapatite, even though the latter is more stable. To explain the difference in growth rate, let us consider the lower edge of the figure as the surface of either crystal. Whether it grows like octacalcium phosphate or hydroxyapatite would appear to depend on whether a phosphate (atom 14) or a hydroxyl ion fills the corner position of the hydroxyapatite unit cell. The hydrogen phosphate ion pictured here has oxygen to calcium distances of 2.37, 2.39 and 2.63 Å and a hydrogen bond of 2.46 Å (20–36). A hydroxyl in the position of oxygen number 35 would have only two comparable calcium to oxygen distances, and only a weak hydrogen bond if any. This difference plus the fact that the hydroxyl ion in the surrounding solution would be present in much lower concentrations than the phosphate ions under physiological conditions would make it appear that generally there will be many more phosphates than hydroxyl in the surface positions. The size of the phosphate ion would prevent the completion of the hexagon around the hydroxyl position necessary for the hydroxyapatite structure since two of the hexagon positions are occupied by oxygens of the central phosphate (atom 14). Thus, phosphate appears to act like a crystal poison for lateral growth. Consistent with this hypothesis hydroxyapatite tends to form long needles[1]. The greater stability of hydroxyapatite appears logical since it achieves much better packing than does octacalcium phosphate. There are two calciums in each half of the 'water layer' of octacalcium phosphate (not shown here) close to those that they would have as columnar calcium in hydroxyapatite, but they are surrounded by only seven oxygens rather than the nine they would have in hydroxyapatite. In addition, the octacalcium arrangement creates a channel down the middle of the octacalcium unit cell along the c-axis, in which two water molecules are loosely held as shown by the ease with which they are lost[1,2].

I thank Mr. Robert Reedy for assistance with the computer and Dr. Isaac Feldman for advice.

CHEMISTRY

Production of Acetylene from Coal, using a Plasma Jet

THE plasma jet is a convenient tool for the production of high temperatures (8,000°–15,000° K). It has been shown, in these laboratories, that the thermal decomposition of coal in a pure argon plasma results in about 20 per cent conversion of the carbon in the coal to carbon in acetylene, and that the addition of 10 per cent of hydrogen to the arc gas increases this conversion to about 40 per cent. The high-temperature stability of acetylene[1] and the rapid quenching provided by the jet are the main factors favouring this conversion.

The experiments were carried out with a plasma jet of conventional electrode arrangement, similar to that used by Leutner and Stokes[2] for the conversion of methane to acetylene but with easily removable electrodes. An electric arc was struck between a tungsten rod which acted as the cathode and a copper tube as the anode. The electric power was supplied from a welding generator, with an open circuit voltage of 80 V. The power consumption was about 6 kW with the pure argon plasma, increasing to about 9 kW when operating on the argon/hydrogen mixture.

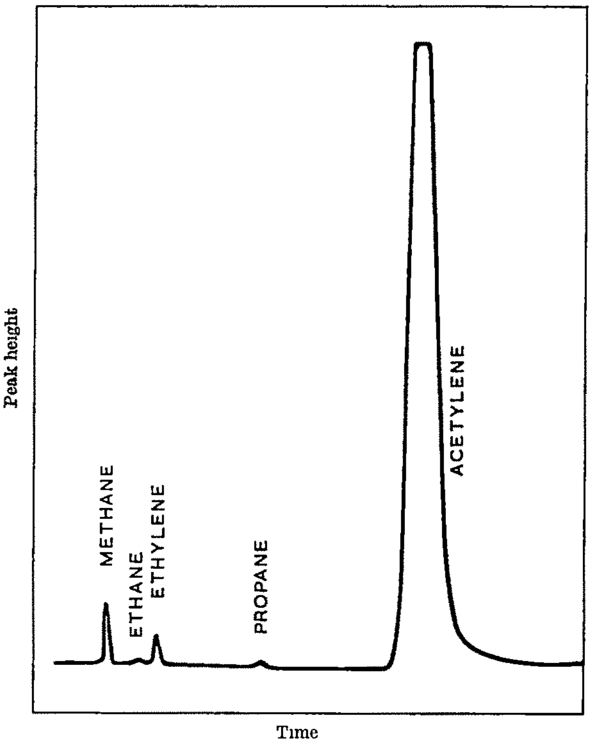

Fig. 1. Gas-chromatographic analysis of hydrocarbon gases. Methane, 0.014 per cent, ethane, 0.001 per cent, ethylene, 0.005 per cent, propane, 0.004 per cent, acetylene, 0.54 per cent

A high-volatile coal (83.6 per cent carbon, 5.3 per cent hydrogen, 7.7 per cent oxygen dry-mineral-matter-free basis, National Coal Board Rank Code No. 802) was ground to pass a 72 B.S. mesh sieve. The material was fed at rates of up to 1 g/min into the plasma jet from a fluidized bed by a subsidiary stream of argon. The coal was at first introduced into the primary gas feeding the jet, but this resulted in severe erosion of the electrodes. The coal/argon mixture was, therefore, passed into the region of intense heat through a single small hole drilled radially in the anode. The gases leaving the jet passed into a steel cooling chamber and were afterwards collected in a large polythene container. Chemical analyses were carried out either on the total gas sample in the polythene container (for wet chemical analysis) or on samples taken from the container (for gas-chromatographic or infra-red analysis).

The reaction products from the thermal decomposition of the coal in the plasma jet were almost entirely either solid (soot) or gaseous, there being negligible amounts of material of tarry nature that normally results from the thermal treatment of coal at relatively low temperatures and at slow rates of heating.

Gas-chromatographic analysis of the arc gas (Fig. 1) showed that acetylene represented more than 95 per cent of the hydrocarbons present. Calculation of the percentage conversion of the carbon in the coal to carbon in acetylene indicated that the yield of acetylene is considerable at the temperatures and under the thermal gradients prevailing in the jet, although the concentration of acetylene in the arc gas was low owing to the high throughput of argon (about 10 l./min). Maximum conversions of 25 per cent with pure argon and 45 per cent with an argon/10 per cent hydrogen mixture have so far been obtained with the present apparatus. Hydrogen, carbon monoxide and hydrogen cyanide (from the nitrogen in coal) are the other main gaseous components formed.

The elementary analyses of the soot are somewhat similar to those found for carbonized coal that has been heated in the temperature range 600°–800° C This suggests that at least some of the coal may not have reached the high temperatures associated with the arc Optical and electron microscope investigations indicate that the majority of the soot particles are in the submicron range

We thank Mr L A King, of the Electrical Research Association, Leatherhead, for his advice on the construction of the plasma jet, and the British Coal Utilisation Research Association for permission to publish this communication

Detection of Nitric Oxide by Gas-chromatography

In an investigation on the feasibility of using gas-chromatographic methods to determine the oxides of nitrogen in gaseous mixtures such as Diesel exhaust gases, we have successfully used a standard argon ionization cell to detect small volumes of nitric oxide The limit of detection was of the order of 0 01 µl A glass column was used, packed with molecular sieve No *5A*, and fitted to a Pye panchromatograph

The nitric oxide–argon mixtures used were prepared by serial dilution In order to limit the extent to which oxidation of the nitric oxide could take place during the preparation of nitric oxide–air mixtures, the following procedure was adopted A nitric oxide–argon mixture containing 0 1 per cent nitric oxide was first prepared, and aliquots containing the required amounts of nitric oxide were transferred to evacuated gas tubes These tubes were fitted with side arms closed with serum caps through which air was then admitted by the insertion of a hypodermic needle A comparison of the peak heights obtained from nitric oxide–argon mixtures with those obtained from nitric oxide–air mixtures is given in Table 1

Table 1 A Comparison of Nitric Oxide–Argon and Nitric Oxide–Air Mixtures

Nitric oxide (µl)	Peak height response (mm) Nitric oxide–air mixture	Nitric oxide–argon mixture
0 1	38 0	56 0
0 08	31 0	39 5
0 06	27 5	31 0
0 04	17 0	19 5
0 02	9 0	9 0
0 01	6 0	6 0

Column, 5 ft length molecular sieve No *5A* at 100° C, detector, argon ionization cell, 1,750 V, argon flow-rate, 36 ml /min

In the presence of oxygen (air) some oxidation of the nitric oxide occurred, but this diminished as the volume of added nitric oxide was reduced

We have confirmed the results of previous workers[1,2], who indicated the necessity of pretreating the column ('conditioning') in order to obtain reproducible results We have also been able to observe the non-linearity of the adsorption isotherm as an appreciable increase in retention time with decreasing nitric oxide concentration This is shown for the range 0 1–1 µl in Fig 1 In Fig 2, these chromatograms have been superimposed to show that the peak maximum appears to follow the trailing edge of the nitric oxide response As the retention time is a function of the amount of nitric oxide added, it should be possible to use this measurement for analytical purposes in place of the more usual peak height or peak area response This would give increased accuracy at the lower concentration-levels where the retention time can be recorded more accurately

Temperature as a Variable in Ion-exchange Paper Chromatography

Temperature is a variable which has received relatively little attention in chromatographic studies This is particularly true of paper chromatography in which more attention is given to controlling temperature as an aid to reproducibility than to using temperature to effect improved resolution.

In ion-exchange column chromatography effective use is made of changes in temperature[1]. The advantages claimed, however, are mainly associated with improved kinetics of the chromatographic process Specific effects, such as varying positions of chromatographed peaks, which cannot be assigned simply to the temperature dependence of *p*H have been observed but no systematic examination has been made of the effect of temperature on selectivities

This communication is an account of part of a general investigation of the effect of temperature on ion-exchange paper chromatography and was stimulated by the results of an earlier investigation which demonstrated the marked

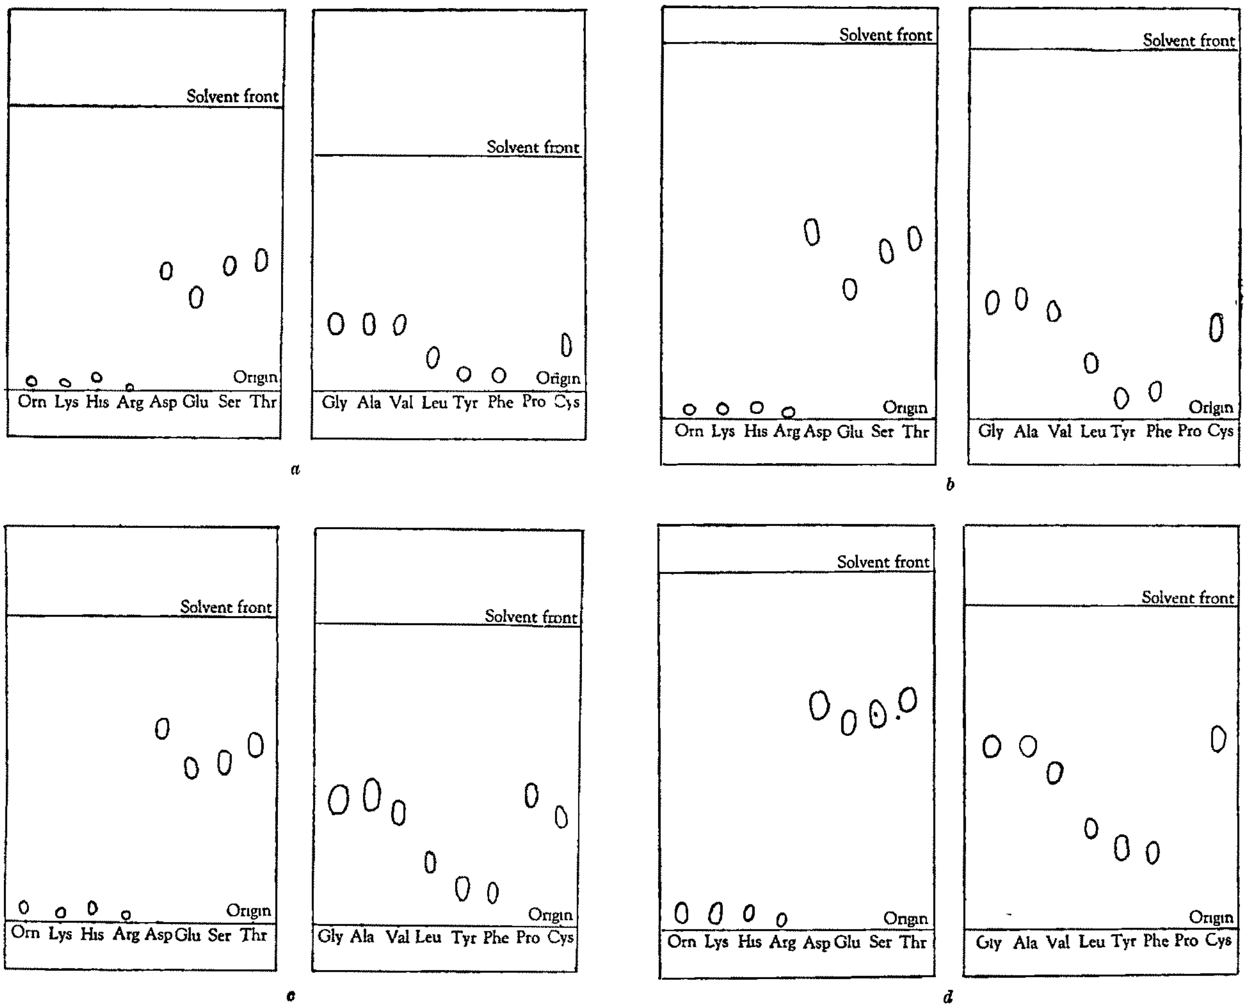

Fig. 1. Chromatograms showing the effect of temperature on one-dimensional separations of amino-acids on Whatman 'Zeo Karb 225' resin-loaded paper. Developing solvent, 0.2 M, *p*H 3.1 (20° C) sodium buffer. Temperature of development, (*a*) 3° C, (*b*) 20° C, (*c*) 45° C, (*d*) 75° C.

dependence of amino-acid sequence on non-ionic interactions between amino-acid side-chain and exchanger matrix[3].

Whatman 'Zeo Karb 225' resin-loaded paper (experimental product) was used throughout this investigation, the paper being used in its dry sodium form. Standard solutions of individual amino-acids, containing 0.2 g of amino-acid in 100 ml. of 0.01 N hydrochloric acid, were applied as individual spots along a line 1 in. from one edge of a 5½ in. × 4 in. sheet of paper according to previously described methods[2]. Ascending development with 0.2 M, *p*H 3.1 sodium buffer was carried out in a glass tank 7 in. high and 5 in. × 3 in. in cross-section. The tank containing the solvent was placed in a thermostatically controlled oven and the solvent allowed to attain the temperature of the oven before development of the chromatogram.

Chromatograms obtained at different temperatures are illustrated in Fig. 1. R_F values of the individual amino-acids and *p*H of the developing solvent at different temperatures are recorded in Table 1.

The amino-acids were applied to the paper in a sequence which allowed easy comparison of different side-chain structures. This is illustrated in Fig. 2, which is a reproduction of the separation at room temperature.

Fig. 1 and Table 1 show that there is a general increase in R_F values of the amino-acids with increasing temperature and that the changes in temperature are accompanied by changes in the relative positions of the individual amino-acids.

The degree of separation of the amino-acids is determined by the resultant of selective interactions between charged sites on the exchanger and on the amino-acid and between exchanger matrix and amino-acid side-chain. At room temperature, under the conditions of development used in this investigation, non-ionic interactions exert a significant influence on resolution. At elevated temperatures the non-ionic binding forces weaken relative to the ionic binding forces and as a result the relative rates of movement of the amino-acids change. The largest changes are associated with those amino-acids which interact most strongly with the exchanger matrix.

Table 1. EFFECT OF TEMPERATURE ON R_F VALUES AND BUFFER *p*H

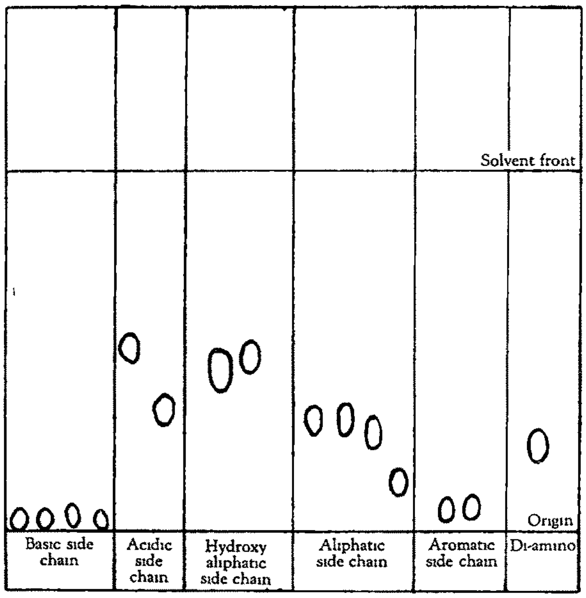

Fig. 2

Temperature dependence of *p*H (Table 1) and ionization of the amino-acids will also contribute to variation of R_F values with temperature. Each of these effects will tend to suppress the other, however, such that their resultant influence on R_F values will be relatively small[2].

The significant effect of changes in temperature on the R_F values of the acidic amino-acids cannot be explained in the foregoing terms, however, since the low degree of ionization of these, relative to the other, amino-acids does not support sufficiently strong interaction between their side-chain structures and the exchanger matrix.

It has previously been suggested that, by virtue of their low degree of ionization, the acidic amino-acids are retarded relative to the other groups by the operation of an ion exclusion effect[2]. In the case of these amino-acids, therefore, the dependence on temperature of R_F values probably results from a change in diffusion rates within the exchanger leading to a reduced selective penetration of these amino-acids at higher temperatures.

The influence of changes in temperature on zone definition is masked in ion-exchange paper chromatography by the simultaneous effect of temperature on rate of flow of the developing solvent. Some increased sharpness of zone formation with increasing temperature was observed, however.

The foregoing results have shown that temperature can be used, particularly, to vary the relative influence of ionic and non-ionic binding forces between amino-acids and exchanger and in consequence the relative rates of movement of amino-acids on a chromatogram.

Kinetics of Isotope Redistribution Reactions

When a hydrocarbon with N equivalent, exchangeable hydrogen atoms is subjected to protium–deuterium exchange, molecules with 0, 1, . . . j . . . N deuterium atoms are formed, which we shall denote by . . . D_j . . . and their fractions by . . . d_j . . . . Neglecting isotope effects, the average degree of deuteration σ, expressed by

$$\sigma = \frac{1}{N}\sum_{j=1}^{N} j d_j \qquad (1)$$

which changes according to the exponential rate law for exchange[1,2].

Let us define a set of variables u_i

$$u_i = (-1)^i \sum_{j=i}^{N} \frac{j!}{i!\,(j-i)!}\, d_j \qquad (2)$$

Then the variable u_1 is directly related to σ

$$u_1 = -\sum_{j=1}^{N} j d_j = -N\sigma \qquad (3)$$

and the exchange rate law in terms of u_1 (at time $= t$) becomes

$$u_1 - u_1(\infty) = [u_1(0) - u_1(\infty)]\exp(-Akt) \qquad (4)$$

where A contains the dimensions of the system under investigation.

Redistribution (or equilibration) experiments constitute another case of isotope reactions. Here, the initial distribution of the isotope over the various isotopic species is not binomial (equilibrium 'statistical'). Equilibrium is approached by redistribution of the isotope within the same chemical compound; the average degree of deuteration σ (or u_1) is constant and hence equation (4) loses its meaning.

We have found from a fairly involved argument, the details of which will be published shortly[3], that the rate law governing redistribution reactions is analogous to equation (4). The variable u_2 is thus defined, according to equation (2), by

$$u_2 = \sum_{j=2}^{N} \frac{j!}{2!\,(j-2)!}\, d_j \qquad (5)$$

and it follows from exponential kinetics

$$u_2 - u_2(\infty) = [u_2(0) - u_2(\infty)]\exp(-A'k't) \qquad (6)$$

Two comments, elaborated elsewhere[3], concern the analogy of the kinetics for exchange (4) and redistribution (6). First, the ratio of k (4) and k' (6), as evaluated from corresponding systems, provides information about the reaction mechanism. Secondly, the redistribution rate law (6) lacks the complete generality of that for

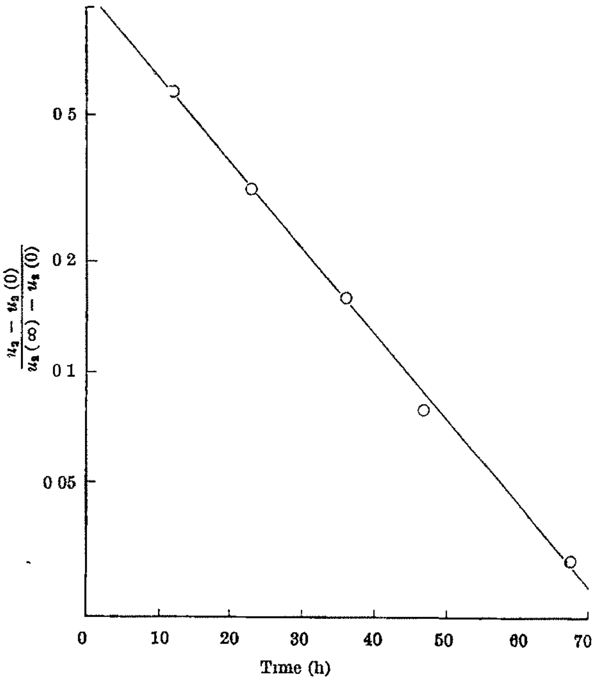

Fig. 1. Data of Wright and Taylor (ref. 4) (experiment denoted as *B*9) on the redistribution of hydrogen isotopes in methane over a nickel catalyst plotted according to an expression equivalent to equation (6)

exchange (4). It might fail for some, conceivable but presumably rare, reaction mechanisms. It certainly does hold for a stepwise process, that is, one proceeding by consecutive reactions, or for any process in which only one isomer D_2 (and, consequently, D_{N-2}) exists, as is the case for methane.

Fig. 1 illustrates the application of the redistribution rate law (equation (6)) to literature data[4] for methane. In this case ($N = 4$) u_2 equals: $1[CH_2D_2] + 3[CHD_3] + 6[CD_4]$. The complementary function $1[CH_2D_2] + 3[CH_3D] + 6[CH_4]$ may, of course, be used equally well. The previous[4] analysis of these kinetic results, based on exponential kinetics for each of the isotopic species, is without foundation. Such kinetics will only hold for either special initial conditions or for special mechanisms.

The simplest redistribution reaction concerns $N = 2$. The example most frequently investigated, particularly in heterogeneous catalysis, is:

$$H_2 + D_2 \rightleftharpoons 2\,HD$$

Exponential kinetics for [HD] (and the other isotopic species) are commonly observed. This result is another illustration of the redistribution rate law (equation (6)), since $u_2 = [D_2]$, and [HD] is linearly related to $[D_2]$ by the material balance.

Partition Coefficients and Biological Activities

It was found[1] some time ago that the toxicities C_t of many physically toxic compounds could be estimated by the equation:

$$\text{Log}_{10}\, C_t/C_B = kP \qquad (1)$$

where k is a constant equal to 0·012, C_B is a measure of the intensity of the toxicity, and P is the parachor, which is used as a measure of molecular volume. Equations similar to (1) have been used successfully for the estimation of partition coefficients[2], x, for organic compounds between organic solvents and water and of solubilities[2,3] of organic compounds in water. When substances interact with a solvent, for example, by hydrogen bonding with the water, a further term E_A is required in the equation so that, for example:

$$\text{Log}_{10} x = kP + E_A \qquad (2)$$

This equation (2) was tested[2] on figures given by Collander[4] for partition coefficients x between isobutanol and water and between ether and water with k equal to 0·012 as before. For simple esters and alcohols E_A values were found between − 1 and − 2.

Recently[5,6], the effects of substituents on the biological activity of phenoxyacetic acids as plant hormones and on the toxicities to bacteria for analogues of chloromycetin have been related to two variables. The first is the well-known Hammett sigma factor σ and the second π is the logarithm of the ratio of the partition coefficients of the substituted, x^S, and unsubstituted, x^H, compounds respectively between 1-octanol and water at about 27° C. From equation (2):

$$\pi = \text{Log}_{10} x^S - \text{Log}_{10} x^H = 0{\cdot}012\,(P^S - P^H) + E_A{}^S - E_A{}^H \qquad (3)$$

Table 1 shows that the values of π for unionized phenoxyacetic acid molecules do agree well with 0·012 $(P^S - P^H)$ when the substituents contain only carbon and hydrogen. For such cases $E_A{}^S - E_A{}^H$ would be expected to be zero. The parachors were calculated by a method previously described[7]. Except for fluorine attached directly to the aromatic nucleus $E_A{}^S - E_A{}^H$ for halogen compounds is about + 0·35 (Table 2). The positive sign means that the interactions have increased the solubility in 1-octanol relative to water. All other interactions have so far been found to be negative. In the estimation of physical toxicities and solubilities no interaction terms seemed to be required for alkyl and aryl halides[2,3]. Figures for ortho-substituents are not given in Table 2 or in the following list because the oxyacetic acid group will itself interact with water and groups close to each other do not appear to interact independently[2]. The $E_A{}^S - E_A{}^H$ values calculated for the other groups are: 3–OCF_3, + 0·28; 3–SCH_3, − 0·49; 3–NO_2, − 0·57; 4–NO_2, − 0·61; 3–OCH_3, − 0·64; 3–SO_2CF_3, − 0·72; 3–OH, − 0·78; 4–OCH_3, − 0·79; 4–OH, − 0·89; 3–CN, − 0·92; 4–CN, − 0·91; 3–COOH, − 0·97; 4–$N{=}NC_6H_5$, − 1·16; 3–$COCH_3$, − 1·38; 4–$COCH_3$, − 1·44; 3–$NHCOCH_3$, − 2·21; 3–SO_2CH_3, − 2·77. With the exception of 3–OCF_3, all these values are negative.

Table 1

Substitution	π	$0{\cdot}012\,(P^S - P^H)$
None	0	0
2—CH_3	0·68	0·48
3—CH_3	0·51	0·48
4—CH_3	0·52	0·48
2—C_2H_5	1·22	0·96
3—C_2H_5	0·97	0·96
3,4—$(CH_2)_3$	1·06	1·07
3,4—$(CH)_4$	1·27	1·25
3,4—$(CH_2)_4$	1·40	1·55
3—n C_4H_9	1·91	1·91
3—C_6H_5	1·91	2·07

Table 2

Substitution	π	$0{\cdot}012\,(P^S - P^H)$	$E^S_A - E^H_A$
3—F	0·13	0·06	+ 0·07
4—F	0·14	0·06	+ 0·08
3—Cl	0·76	0·42	+ 0·34
4—Cl	0·70	0·42	+ 0·28
3—Br	0·95	0·59	+ 0·36
4—Br	1·02	0·59	+ 0·43
3—CF_3	1·09	0·67	+ 0·42
3—I	1·17	0·88	+ 0·29
4—I	1·26	0·88	+ 0·38
3—SF_5	1·51	1·15	+ 0·36
3—SCF_3	1·59	1·22	+ 0·37

The equation (3) should prove useful for the estimation of values of π. The term $0{\cdot}012(P^S - P^H)$ can be calculated immediately. It will be the same whenever a given substitution is made and equals π when the substitution involves only addition of carbon and hydrogen. The E_A values for an isolated interacting group and a given type of organic solvent appear to be nearly constant[2,3] so that it will often be possible to suggest a value for $E^S{}_A - E^H{}_A$. However, interaction energies do depend on the solvent and too much confidence should not be placed in values obtained from the partition coefficients because 1-octanol might give interaction energies which differed considerably from those for the biophase. Hansch *et al.*[6] realized this and when the value of π of − 1·26 for 3–SO_2CH_3 from 1-octanol proved unsatisfactory, they suggested that a value of π equal to − 0·47, which gave good agreement with all the biological results, should be used.

Molecular Configuration of Benzil and α-Pyridil

THE molecular configuration of benzil has been the object of considerable interest for some time because of unusual physical characteristics, such as its large optical rotatory power. Caldwell and Le Fevre[1] measured its dipole moment in several solvents and compared it with that of phenanthroquinone, which is planar and contains two *cis* carbonyl groups. From the lower (3·5 *D*) electric dipole moment of benzil these authors concluded that the molecule must be skew and that the two C_6H_5—C=O halves must lie in two different planes making an angle of 90°–100° with each other.

Knaggs and Lonsdale[2] compared this suggestion with their X-ray diffraction results and found that it was quite reasonable. Furthermore, they concluded that neither a planar *cis* nor a planar *trans* configuration was acceptable for the interpretation of their X-ray data. Finally, Le Fevre *et al.*[3] have estimated from dielectric and Kerr constants that the molecule is twisted about the O=C—C=O bond.

In connexion with some work on 2,2′-dipyridyl glyoxal (α-pyridil), we have recorded the infra-red spectrum of benzil and of the foregoing substance. Comparison of our results with that in the literature revealed that previous measurements[4,5] of the infra-red spectrum of benzil showed a single band in the carbonyl region (1,700 cm^{-1}) and, furthermore, this was used as evidence[5] for a *trans* structure for benzil, in contrast with the results quoted above. We find two bands in the carbonyl region for both benzil and α-pyridil, as shown in Fig. 1, *A* and *B*. The splitting in benzil is about 14 cm^{-1} while in α-pyridil it is 23 cm^{-1}. Our results, together with that of other workers, are presented in Table 1.

The structure of α-pyridil was worked out in detail by Hirokawa and Ashida[6], who found that the molecule is rotated about the O=C—C=O bond by an angle of approximately 83 degrees. Since such a conformation makes the relevant point group of the molecule C_2, one should observe two carbonyl bands for this molecule. Fig. 1, *B* shows that this is the case. By analogy with α-pyridil, two carbonyl bands should be seen for a benzil molecule in the skew configuration discussed here, and this is shown in Fig. 1, *A*, to be true.

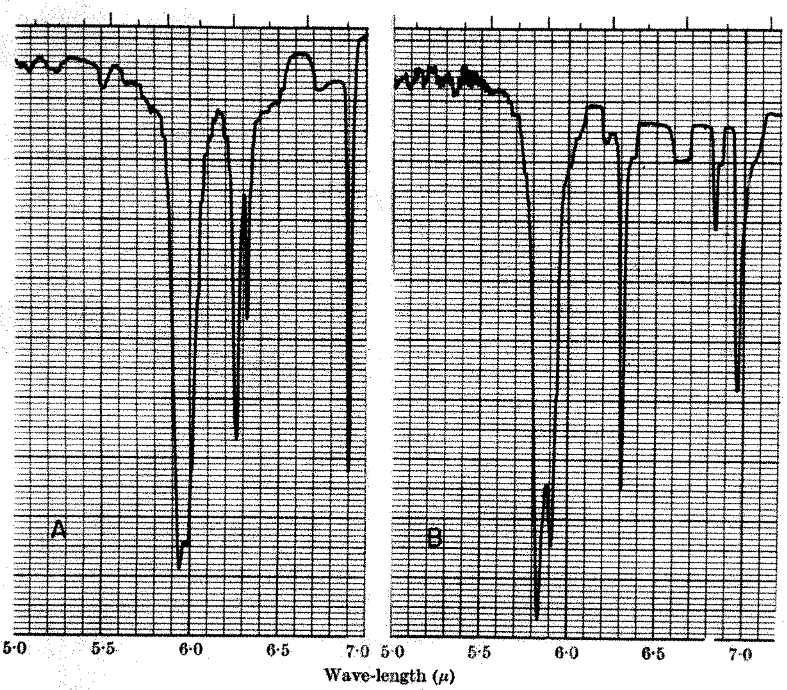

Fig. 1. *A*, Spectrum of benzil in chloroform; *B*, spectrum of α-pyridil in chloroform. Both solutions were approximately 0·03 M

Table 1

Ref.	Benzil	α-Pyridil
This work	1,686 cm^{-1} (*st, sp*)	1,715 cm^{-1} (*st, sp*)
	1,672 cm^{-1} (*sh*)	1,692 cm^{-1} (*st, sp*)
4	1,652 cm^{-1}	—
5	1,681 cm^{-1}	—

st, strong; *sp*, sharp; *sh*, shoulder.

The spectra were recorded using a Perkin–Elmer 237 grating spectrophotometer with IRTAN cells. Using an older spectrophotometer and the same solution used to record Fig. 1, *A*, we were unable to observe the splitting of the carbonyl band in benzil. As a result, the apparent conflict of the infra-red results with the other measurements is due to lack of resolution in the older spectrophotometers.

BIOPHYSICS

Viscosity of Deoxyribonucleic Acid Solutions in the 'Sub-melting' Temperature Range

DEOXYRIBONUCLEIC acid (DNA) 'melting' has been mainly investigated using spectroscopic and optical rotation techniques[1]. To our knowledge, the viscosity behaviour associated with the 'melting' phenomenon has been examined only in the special cases of synthetic deoxyribopolynucleotides[2] and phage DNA[3]. In an investigation of this subject, using DNA preparations from three different sources, it was observed that the change in intrinsic viscosity parallels the change in optical density at 260 mμ, except for the 'sub-melting' temperature range. The peculiar behaviour found in this region is reported here. Briefly, this is characterized by a fall in viscosity which is completely reversed on cooling and seems to be caused by the local melting of deoxyadenylic-thymidylic (dA-T) clusters.

Viscosity was measured using a four-bulb viscometer built according to Eigner[4]. The average velocity gradients associated with each bulb were calculated using Kroepelin's formula[5]: values ranging from 100 to 20 sec^{-1} were found. Three DNA preparations (from calf thymus, chicken erythrocytes and *E. coli*, respectively), obtained essentially according to Kay *et al.*[6] and displaying intrinsic viscosities close to 70 dl./g, were used at concentrations of 20 μg/ml. in acetate buffer $\mu = 0·15$, *p*H = 5·6 (the *p*H of this buffer did not show any significant change within the explored temperature range). The viscometer was equilibrated at several different temperatures and fresh aliquots from stock DNA solutions were measured at each temperature. Ultra-violet 'melting profiles' were obtained at essentially the same DNA concentration used in the viscosity experiments.

Fig. 1 shows the behaviour of both optical density at 260 mμ and intrinsic viscosity at zero velocity gradient of calf thymus DNA as a function of temperature. Substantially similar results were obtained

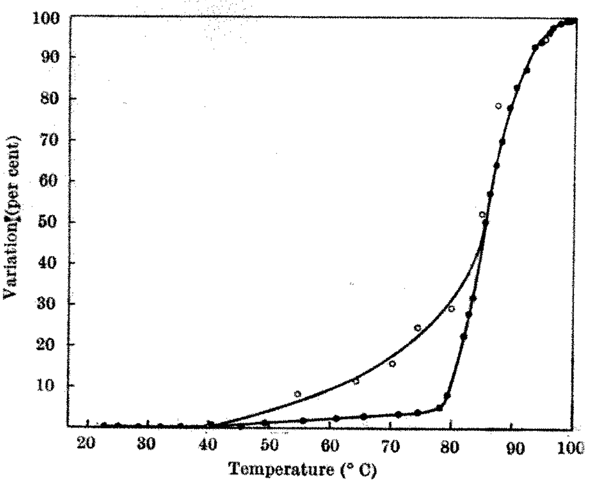

Fig. 1. Viscosity and optical density of calf thymus DNA (sample *B* 18) as a function of temperature. Viscosity decrease (○) and optical density increase (●) are given as percentage of total variation. DNA concentration was about 20 μg/ml. in acetate buffer *p*H = 5·6, $\mu = 0{\cdot}15$

with the other two samples. It is evident that viscosity undergoes a quite distinct drop in a temperature range where optical density is very slowly increasing in a linear fashion. Results to be published in detail elsewhere indicate that in the temperature range 50°–80° C, DNA hydrolysis occurs according to a 'double hit' mechanism, at a very slow rate and shows a lag-time of more than 40 min. Therefore, the results shown in Fig. 1 (in the range 50°–80° C), which were obtained within 20 min after introducing the solutions in the viscometer, do not need any correction for hydrolysis phenomena. Viscosity results in the temperature range 80°–95° C were corrected for hydrolysis.

In phosphate buffer *p*H 7·6, $\mu = 0{\cdot}15$ (where the melting point is the same as at *p*H 5·6), the difference between the viscosity and optical density curves was less pronounced.

When the temperature was lowered from the 'submelting' range down to 25° C (no matter how fast was the drop) a complete recovery of the initial viscosity value was obtained.

The foregoing results suggest that the 'sub-melting' behaviour of viscosity is due to a change in the configuration of DNA molecules. That this change is not related to some trivial aggregation phenomenon mediated by residual protein seems to be suggested by its reversibility. A possible explanation is that it is due to the local melting of dA-T clusters, the existence of which, in runs of up to 9 units, has been shown by Spencer and Chargaff[7]. In connexion with this interpretation it may be recalled that the melting temperature of a synthetic dA-T polymer is about 65° C (ref. 8), well within the range where the 'submelting' phenomenon occurs in DNA, and that Greer and Zamenhof[9] found that although guanine is more labile than adenine at high temperatures, depurination almost exclusively affects adenine at temperatures below the 'melting point'.

We thank Prof. C. Sadron for his advice.

Photoconduction of Adenosine in Various Morphological Forms

Optically clear films can be cast on a substrate when a neutral adenosine aqueous solution is slowly evaporated at about 60° C. Along the perimeter of the film, white needle-shaped crystallites are observed. If the film is exposed afterwards to high humidity, its clear portion will become cloudy. When viewed under the microscope between crossed nicols, this cloudy portion is seen to consist entirely of spherulites as shown in Fig. 1. The infra-red spectra of: (1) potassium bromide pellet of powdered needle-shaped crystallites; (2) non-spherulitic clear film; (3) spherulitic film of adenosine are shown in Fig. 2. From these spectra it is evident that the molecular arrangements of adenosine in these three morphological forms are different. Further work has to be done in order to elucidate the structures of the material in these various forms. In the present work it is intended to report some results on semi- and photo-conduction of the three different morphological forms of adenosine surface cells.

The experimental details for measuring the conduction of organic materials are similar to those reported previously[1]. The temperature dependence of the resistance of adenosine is shown in Fig. 3. Except for the deviation towards the lower temperature end, the resistance follows the well-known equation $R = R_0 \exp (E_d/2kT)$, where R_0 is a constant and E_d is the activation energy for dark conduction. The activation energy of the pellet is 4·52 eV, in agreement with the value reported by Eley and Leslie[2]. The activation energies of the spherulitic and non-spherulitic films are 4·03 and 3·68 eV respectively. The temperature dependence of photocurrent of adenosine shown in Fig. 4 follows the equation $i = i_0 \exp (-E_p/kT)$, where i_0 is a constant and E_p is the activation energy for photoconduction. The values of E_p are about 1·90 eV for the pellet, 1·87 eV for the spherulitic film, and 1·73 eV for the non-spherulitic film.

The activation energies for dark- and photo-conduction of adenosine are much higher than the corresponding values of polyadenylic acid[3] and NaDNA in the dry state[4].

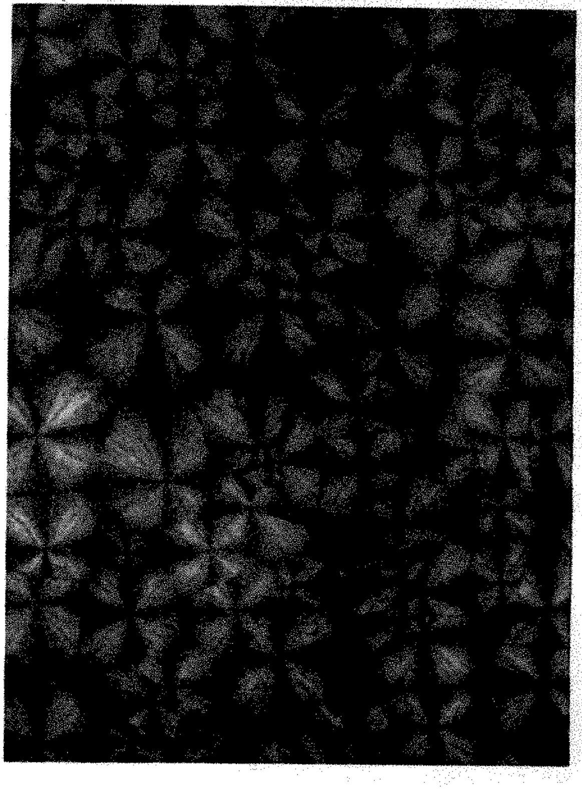

Fig. 1. Adenosine spherulites (crossed nicols × 385)

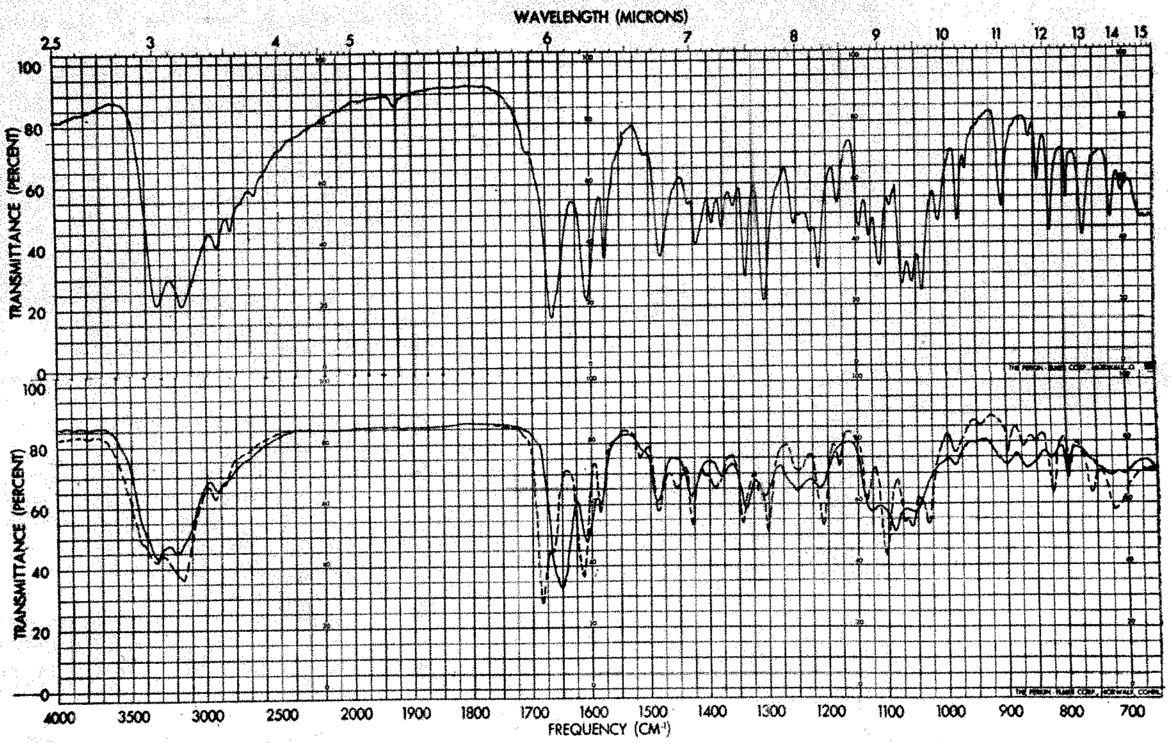

Fig. 2. Infra-red spectra of adenosine samples. Top, potassium bromide disk of powdered needle-shaped crystallites; bottom (solid curve), clear film on silver chloride plate; (dotted curve), same film exposed to high humidity and dried (spherulitic film)

These higher values may be largely due to the higher barrier between neighbouring molecules of this nucleoside. Let us assume that the energy required for electronic conduction in adenosine is due partly to the energy E_N required for charge carrier generation and partly to the energy E_μ required to overcome the barriers for charge carrier transport. Then we have[4] $E_d = E_N + E_\mu$, $E_\mu = 2E_p$, and $E_N = E_d - 2E_p$. From the experimental results E_N can be calculated to be about 0·72 eV for the pellet, 0·29 eV for the spherulitic film, and 0·22 eV for the non-spherulitic film. It may be noted that white light with peak intensity near 1,200 mμ was used for photocurrent measurement. The carrier generated by such a light radiation may not be due to the excitation of the π-electrons in the bases, since such an excitation would require a light source of wave-lengths near 259 mμ, the

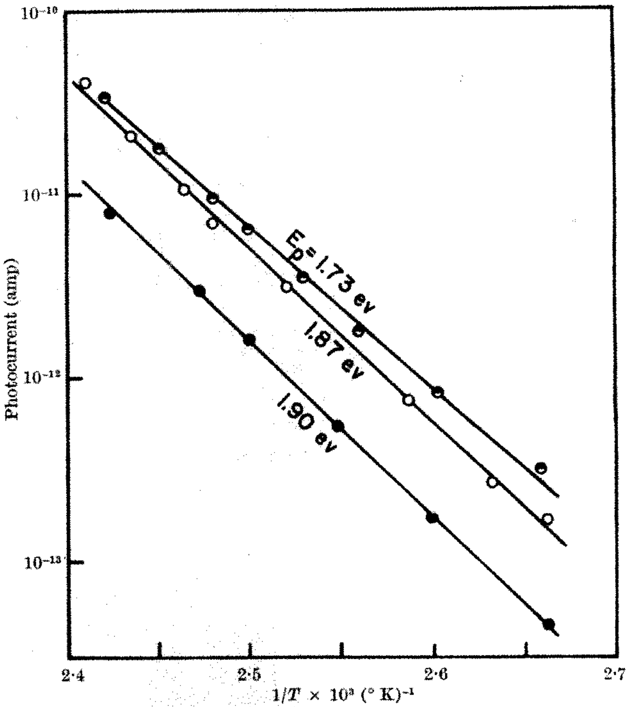

Fig. 4. Photocurrent of adenosine versus inverse absolute temperature. Solid circles, pressed pellet from powdered needle-shaped crystallites; open circles, spherulitic film; half-open circles, non-spherulitic film

absorption maximum of adenosine. It is assumed that the carriers are excited from impurity- or imperfection-levels, and the small values of E_N calculated are in agreement with this point of view.

It has been noted that the measured value of E_p for a given sample does vary somewhat from measurement to measurement. The small difference of E_p for adenosine obtained for the various morphological forms may thus not be considered as significant. It is concluded that the value of E_p is primarily a measure of the average barrier between neighbouring adenosine molecules and the effect due to morphological differences is rather small.

Periodogram Analysis of Precipitates

Thiele *et al.*[1] have provided many examples of partially periodic precipitation phenomena, some of which resemble in a surprising manner the patterns found in tissues. The analysis of these patterns has a special interest because the pattern of the periodic precipitates is not quite regular, but more or less influenced by chance or by more than a single factor.

The material to be analysed is in the form of electron microscope negatives on pieces of film 2 cm × 2 cm, kindly sent to me by Prof. H. Thiele. These pieces fit into the graduated disk of a scanning apparatus already described[2], in which they can be oriented and scanned at any angle from 90° to −90°. The apparatus consists of a microscope with a modified motor-driven stage, a photocell, an amplifier, and a recorder. It is calibrated with standard neutral filters to measure optical density. Sometimes the precipitates appear to be arranged in one direction rather than another; it may then be convenient to place the film in the graduated disk so that this direction lies along the line joining 90° and −90°, but there is often much uncertainty in making this adjustment.

The negative is scanned at 20° angles from 90° to −70°, that is, in 9 different directions. This results in 9 periodograms, on which two kinds of calculation can be carried out. The first is to take each periodogram separately and to find the frequency with which maxima and minima occur. If there are M maxima and minima in a scanning distance of 10,000 Å, the half-period P_1 will be $10{,}000/M$, and there will be one such value for each periodogram. This tells us nothing about the size of the maxima and minima. The second kind of calculation is to find the mean and the standard deviation (root-mean-square deviation) for each of the 9 periodograms, and then to plot the standard deviation against the scanning angle θ. The result is a curve which shows maxima and minima, usually occurring regularly. After completion of this second kind of calculation, the average value of P_1 which corresponds to the largest half-periods P_2 of the σ versus θ graph can be selected as being specially interesting, and can be called $P_{1\max}$; alternatively the values of P_1 for all 9 periodograms can be tabulated.

If the periodic precipitates were entirely regular, the minimum value of the standard deviation provided by the second kind of calculation would be zero, but for the material under consideration it is h, which can be interpreted as a measure of the extent to which a regular arrangement is disturbed by secondary factors or by chance irregularities. These disturbances lead to an increase in the value for the minima and to a decrease in the value for the maxima, and if the value for the maximum of the σ versus θ graph were M in the case of a regular periodic precipitate, it would be $(M - h)$ when the entirely regular arrangement was disturbed by secondary factors or by chance.

Table 1

	Half-period P_2 (radians)	Half-period $P_{1\max}$ (Å)	h	Amplitude of *S.D.*
Copper alginate	1·57	1450	0·23	0·24–0·42
Cadmium alginate	1·57	1100	0·24	0·25–0·45
Sodium alginate	n.s.	n.s.	0·17	n.s.*
Copper alginate †	0·70	760	0·25	0·20–0·40
Cadmium alginate †	0·61	830	0·23	0·23–0·50
Lead alginate †	0·53	910	0·24	0·25–0·61
Lead pectinate	1·57	1000	0·12	0·12–0·30

* Not significant.
† Probably represent mixtures.

The periodic precipitates of micelles which Prof. Thiele has sent me give the values shown in Table 1.

There are two important special cases. The first is when the material is precipitated at random, as in the case of sodium alginate or in the case of the human red cell ghost[2]; then the period and the amplitude of the oscillations are not significantly different at any angle. The second is when there is a mixture of micelles. In this case, the period and the amplitude of the root-mean-square deviation changes significantly in the course of the scanning operation, or the half-period is less than 1·57 radians and the curve of σ versus θ can usually be reduced to two or more curves, each with a half-period of 1·57 radians but with maxima and minima at different scanning angles (for example, the curve for copper alginate seems to be the result of a mixture of two species each with a half-period of 1·57 radians, but the one with a maximum at 20° and the other with a maximum at 90°).

BIOCHEMISTRY

Variant Forms of Arachin

In the past few years, analysis of samples from individual animals has revealed variants of many of the blood proteins. In man, for example, hæmoglobin, haptoglobins, transferrins, albumin and several glycoproteins are known to exist in two or more closely related forms, the distribution of which follows a simple hereditary pattern. In milk, β-lactoglobulin and α-lactalbumin show similar polymorphisms.

So far, I believe that no such polymorphism has been demonstrated in plant proteins though there is no obvious reason why one should not exist. In an attempt to find variants, the proteins of single seeds from Virginia and Spanish strains of peanut (*Arachis hypogaea*) have been examined by using acrylamide-gel electrophoresis[1]. Seeds were homogenized in electrophoresis buffer, centrifuged to remove oil and debris and the protein concentration adjusted to about 2 per cent before electrophoresis. Arachin exists under these conditions in a monomer–dimer form[2]; these are shown in Fig. 1, which also shows the variant, more rapidly migrating form found in some of the seeds of the Virginia strain. The form with highest mobility is called arachin *A* and the slower arachin *B*. Although the differences are most clearly seen in the monomers, the dimers also showed small differences in mobility. In addition, it was just possible to resolve the two forms by electrophoresis in agar gels at *p*H 8·6.

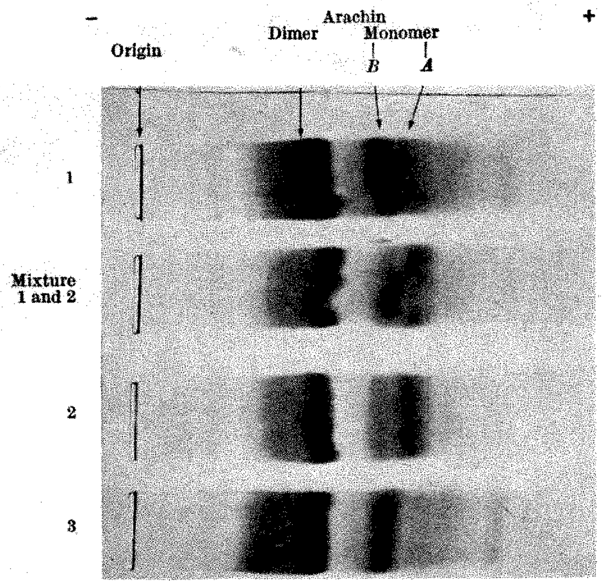

Fig. 1. Polyacrylamide-gel electrophoresis of peanut cotyledon proteins in a *tris*–citrate–sodium hydroxide–borate discontinuous buffer system, *p*H 8·6. Gel concentration was 7·5 per cent. Samples 1 and 2 show two types of mixed seeds; sample 3 contains arachin *B* only

Of 53 seeds examined, 32 were of the *AB* type, while 21 contained arachin *B* only. In some cases it was possible to distinguish between two types of mixed seeds, with either a preponderance of *A* or *B*. In five cases, pairs of seeds were examined, each pair being taken from a single pod. In every case the seeds comprising the pair were identical. This is consistent with a hereditary mechanism and, although no breeding experiments have been done, genetic control of the two forms of arachin is almost certain. All ten seeds of the Spanish variety examined contained both *A* and *B* arachins, but other minor proteins in this strain differed from those in the Virginia. No example contained arachin *A* alone.

Although such a form might be expected by a superficial analogy with known polymorphism the peanut is tetraploid and self-fertile and the genetic situation is quite different from that in animals. It is unlikely that the two forms are controlled by alleles at a single locus and this is not therefore a true polymorphism.

It is clear from Fig. 1 that both arachins may form dimers and the existence of the two forms should be taken into account in interpreting results obtained previously.

Electrophoretic Separation of the Phenolases from Potato Tubers

EARLY investigations of the properties of polyphenol oxidase from plants showed that most preparations catalysed the oxidation of several polyphenolic substrates. In the past few years it has been demonstrated that crude polyphenol oxidase preparations actually are mixtures of several phenol oxidase proteins, each exhibiting unique catalytic and physical properties. Smith and Krueger[2] used a column of hydroxyl apatite and chromatographically separated crude extracts of mushrooms into a series of purified fractions. These contained several enzyme types, including the classical catecholase and cresolase enzymes. Sisler and Evans[3] showed that chlorogenic acid was a better substrate for the crude polyphenol oxidase from tobacco than for a comparable preparation from mushrooms. The ratios of rates of oxidation of chlorogenic acid to rates of oxidation of catechol as catalysed by each of a series of purified extracts from tobacco varied widely, indicating the presence of more than one type of polyphenol oxidase enzyme. Uritani[4] used starch-gel electrophoresis and separated crude extracts of sweet potato roots into three distinct bands each showing a capacity to catalyse the oxidation of chlorogenic acid. From these experiments it seems clear that organisms contain several types of polyphenol oxidase enzymes.

This investigation was undertaken to determine whether the classical phenolase of potato tubers could be separated into more than one active fraction by electrophoretic techniques.

Crude extracts of frozen peelings from commercially available Russet Burbank potatoes were prepared by a modified method of Smith and Krueger[2]. For the preparation 500 g of frozen peelings in 2 l. cold 15 per cent ethanol containing 0·05 M acetate buffer at *p*H 5·3 were homogenized in a Waring blender for 1 min. The mash was strained through cheesecloth and the filtrate centrifuged in a Servall continuous centrifuge at 18,000*g*. The precipitate recovered after centrifugation was mixed with the mash and the entire mixture was resuspended in 0·1 M sodium chloride solution (400 ml. 0·1 M sodium chloride per 500 g of original starting material). Centrifugation yielded the first salt extract, which was discarded. The pulp was resuspended overnight in 0·1 M sodium chloride, using the proportions already described, and the salt extract was collected after centrifugation. The sodium chloride extraction procedure was repeated three times. The three sodium chloride extracts were combined and brought to 70 per cent saturation with solid ammonium sulphate. The precipitate was collected at 18,000*g* and dissolved in 0·01 M phosphate buffer at *p*H 7. The extract was dialysed overnight against 0·001 M phosphate buffer at *p*H 7. In a large-scale fractionation, 40 lb. of potato peelings yielded 275 ml. of dialysed enzyme solution containing 30 mg protein/ml. An assay of the activity of the extract by the methods of Sisler and Evans[3] showed a specific activity of 117 u./mg protein. A sample (92 ml.) of the dialysed preparation was further purified by use of a preparative electrophoresis apparatus in the laboratory of Dr. H. S. Mason. The extract was introduced into an Elphor continuous electrophoretic separator, model *FF*, at a rate of 10 ml./h. *Tris* buffer (0·01 M) at *p*H 7·0 was supplied at a rate of 80 ml./h. The material was subjected to electrophoresis at 2,400 V for a period of approximately 10 h. Forty-nine fractions were obtained, each with a volume of 15 ml.

The fractions were assayed for polyphenol oxidase activity by the indirect assay procedure of Sisler and Evans[3], using chlorogenic acid, catechol and *p*-cresol as substrates. The concentrations of different reactants in a final volume of 3 ml. were: polyphenolic substrate $5{\cdot}7 \times 10^{-5}$ M; ascorbic acid $2{\cdot}8 \times 10^{-5}$ M; ethylenediamine tetraacetic acid 10^{-3} M. One unit of enzyme activity was expressed as an optical density decrease of 0·01 per min at 265 mμ. The protein content of the extract was determined by the method of Lowry *et al.*[1].

The curves in Fig. 1 show that the phenolase enzyme complex from potatoes was separated into two distinct components by electrophoresis. Both components catalysed the oxidation of chlorogenic acid more rapidly than the other substrates tested. The peak fractions (tubes 21 and 37, Fig. 1) showed similar ratios of activity when catechol was compared with chlorogenic acid as substrate. The cresolase activity in relation to the activity with other substrates was greater in the first peak than in the other peaks, showing that cresolase activity was concentrated in the first component.

The pronounced shoulders which preceded the peak fractions in Fig. 1*A* suggest that both components are electrophoretically heterogeneous in relation to phenolase

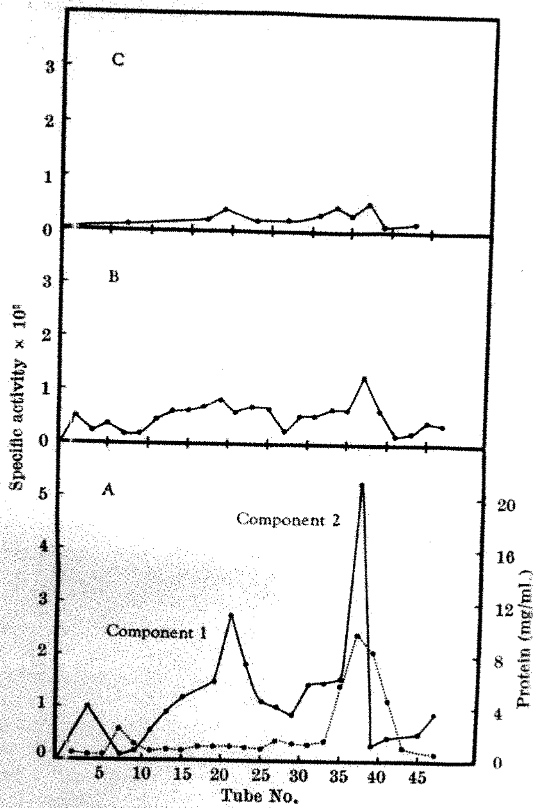

Fig. 1. Purification of an extract from potato tubers by electrophoresis. *A*, Phenolase activity using chlorogenic acid as the substrate; *B*, phenolase activity using catechol as the substrate; *C*, phenolase activity using *p*-cresol as the substrate. ●——●, in *A*, *B* and *C* refers to units per mg protein; ● . . . ●, in *A* refers to mg protein per ml. (this curve also represents the protein content of the enzyme used in *B* and *C*). In this experiment 350,000 units of enzyme (using chlorogenic acid as the substrate) were subjected to electrophoresis and 60 per cent of the total activity was recovered in the fractions

enzymes. The comparison of the chlorogenic acid to catechol activity ratios from the results in Figs. 1*A*, *B* show that the specificity for substrate of certain shoulder fractions is different from the substrate specificity of peak fractions. For example, the ratios of activity with chlorogenic acid (Fig. 1*A*) to activity with catechol (Fig. 1*B*) for shoulder fractions 17 and 33 are 1·6 and 2·6 respectively; whereas, comparable ratios for the peak fractions 21 and 37 are 4·6 and 4·3 respectively. Similarly, the ratios of activity with chlorogenic acid to activity with *p*-cresol for shoulder fractions 17 and 33 are 6·1 and 3·5; whereas the comparable ratios for peak fractions 21 and 37 are 6·9 and 17·5 respectively.

It is clear from the curves in Fig. 1 that crude extracts of potato tubers contain electrophoretically different polyphenol oxidases. Further purification of the proteins that constitute these components will be necessary in order to characterize more completely the different phenolase enzymes from this source.

Effects of X-rays on Nuclear RNA of Lymphatic Cells

THE metabolism of ribonucleic acid in various animal tissues is known to be resistant to ionizing radiation. Recently, nuclear RNA was found by several investigators[1–4] to be inhibited in incorporating its precursors, and further investigations on nuclear RNA seemed necessary to analyse the effects of ionizing radiation on animal cells. In the work recorded here, nuclei of rabbit appendix were used as material, as rapid incorporation of phosphorus-32 into nucleic acids *in vitro*[5] has been found in these isolated nuclei.

Nuclei were isolated from rabbit appendix essentially according to the method of Allfrey and Mirsky[6], using 0·25 M sucrose solution as the suspending medium. The nuclei suspended in the medium, to which were added 5 mM magnesium chloride and 5 μg/ml. streptomycin, were irradiated ice-cold with X-rays, using a filter of 0·25 mm copper and 1·0 mm aluminium, a dose rate of 217 r. or 512 r. per min, 200 kV and 19 m.amp. Immediately after irradiation, the nuclear suspension and the unirradiated control were incubated with 2 μc. ^{32}P/ml. for 30 min at 37° C. The suspensions were then chilled and washed with 0·01 M phosphate buffer, *p*H 7·0. RNA was extracted with 90 per cent phenol by Kirby's method[7]. Nuclear RNA obtained was fractionated with the column of DEAE-cellulose (0·89 m.equiv./mg) by the gradient elution with linearly increasing concentration of sodium chloride up to 1·0 M in 0·01 M phosphate buffer, and finally by 0·5 N sodium hydroxide, collecting the elute each by 4 ml. The amounts of RNA was measured with a spectrophotometer at a wave-length of 260 mμ. Aliquots were taken from eluted samples to count the radioactivity of phosphorus-32 with a Geiger–Müller counter.

Fig. 1 illustrates the chromatogram of normal nuclear RNA. Seven groups of the fractions were separated: *F*–I (fraction I) eluted by the buffer; *F*–II by sodium chloride at 0·1 M; *F*–III at 0·15–0·2 M; *F*–IV at 0·5 M; *F*–V at 0·6 M; *F*–VI at 1·0 M; *F*–CII eluted by 0·5 N sodium hydroxide.

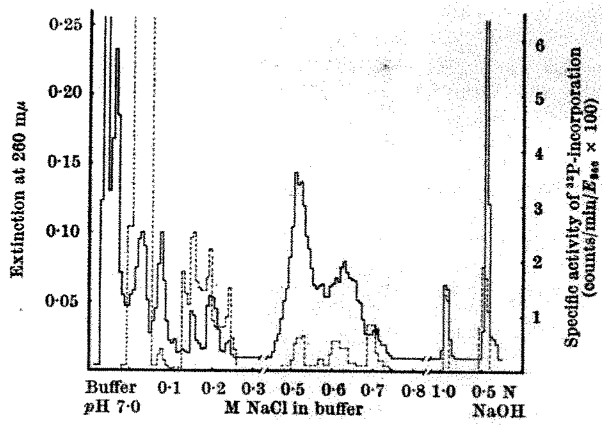

Fig. 1. Chromatographic pattern of normal nuclear RNA. 2–5 mg of phenol-extracted RNA was charged on 1·5 g of DEAE-cellulose. Elution was carried out with sodium chloride of linearly increasing concentration buffered with phosphate buffer at *p*H 7·0, and finally with 0·5 N sodium hydroxide, at the flow-rate of 0·6–0·7 ml./min at room temperature. ——, Amounts of RNA (extinction at 260 mμ); —, specific activity of ^{32}P-incorporation (counts/min/*E*260 × 100)

Irradiation with 1,000 r. caused no significant changes in the chromatographic pattern of RNA. By irradiating with 2,000 r., *F*–IV and V decreased slightly, while *F*–I and II increased as compared with those of normal (Fig. 2). After 10,000 r.-irradiation, *F*–IV and V decreased remarkably, and *F*–I was much more increased than that at the 2,000 r. of irradiation (Fig. 3).

Incorporation of phosphorus-32 into the fractions of RNA was also influenced by X-ray. In the normal nuclei,

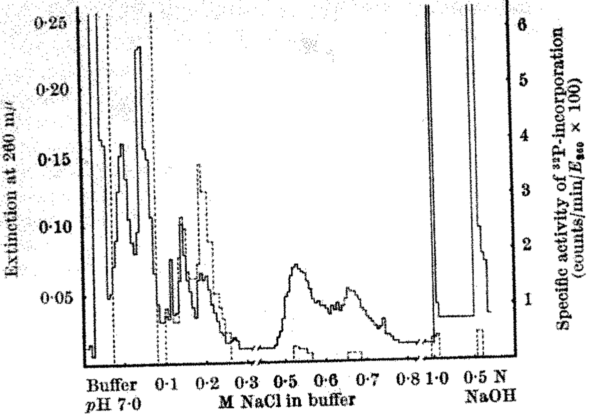

Fig. 2. Chromatographic pattern of 2,000 r.-irradiated nuclear RNA. Nuclear suspension was irradiated with X-ray, at the dose-rate of 217 r./min, followed by the incubation in the 0·25 M sucrose solution with 2 μc. ³²P/ml. for 30 min at 37° C. Other procedures were the same as in the legend of Fig. 1

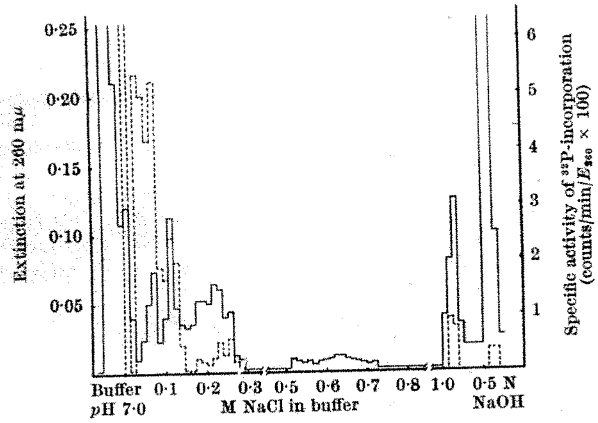

Fig. 3. Chromatographic pattern of 10,000 r.-irradiated nuclear RNA. All procedures were the same as in the legend of Fig. 2; but the dose-rate was 512 r./min

the degree of incorporation was highest in *F*–II, and *F*–III also showed considerable incorporation. Other fractions did not present the high incorporation as such (Fig. 1). These incorporations into the fractions were depressed by the irradiation of 2,000 r. except into *F*–II in which it was accelerated from 1·1 to the extreme case of 400 times normal. 10,000 r. of irradiation caused great inhibition of the incorporation into all fractions. In *F*–IV and V, the incorporation was not detectable and in *F*–II it was only 1/20–1/80 of normal.

This experiment demonstrates that RNA is reduced both in amounts and in the degree of incorporation of phosphorus-32 by X-ray irradiation, and that the RNA incorporating phosphorus-32 at a low rate is more sensitive to X-rays than that incorporating at a high rate.

We thank Dr. M. Kato and Dr. S. Muramatsu for their advice.

Bacteriophage Plaque-count Assay and Confluent Lysis on Plates without Bottom Agar Layer

WITH so much research being carried out on bacteriophage, improvements to simplify and save time in the routine techniques of assay and preparation would be of great value. Having spent considerable time on preparation of 'bottom' agar plates for the agar layer assay by the plaque count method[1,2] and for high-titre bacteriophage stock preparation on a large number of plates by the confluent lysis method[3], we investigated the possibility of saving time by using plates without 'bottom' agar for assay and stock preparation.

The following medium was found satisfactory on glass plates without 'bottom' agar. The components per litre were: Difco bacto-casamino-acids (acid hydrolysed casein) 10 g, Difco bacto-nutrient broth 15 g, sucrose 10 g, dextrose 1 g, crystalline magnesium sulphate 5 g, sodium chloride 5 g, and agar 8 g.

The results for efficiency of plating and for yields are presented in Table 1.

Table 1. PLAQUE FORMATION AND YIELD OF DIFFERENT BACTERIOPHAGES ON PLATES WITHOUT 'BOTTOM' AGAR

Type of bacteriophage	Efficiency of plating by our method* (% plaques compared with standard assay†)	Yields observed (No. of phage per plate) On plates with 'bottom' agar‡	On plates without 'bottom' agar§
*T*1	101·1 ± 5	5·0 × 10¹¹	6·2 ± 10¹¹
*T*2	52·7 ± 5	1·1 × 10¹²	1·1 × 10¹²
*T*3	98·7 ± 5	4·5 × 10¹¹	7·1 × 10¹¹
*T*4	51·2 ± 5	5·8 × 10¹¹	7·9 × 10¹¹
*T*5	53·7 ± 5	9·0 × 10¹¹	1·1 × 10¹²
*T*6	53·2 ± 5	6·0 × 10¹¹	6·6 × 10¹¹
*T*7	104·5 ± 5	3·7 × 10¹¹	4·6 × 10¹¹

* 1·5 ml. of *E. coli* suspension in the log phase of growth and 0·1 ml. of appropriate dilutions of phage in tryptone broth were mixed with 4·5 ml. of our melted medium and poured on sterile Petri dishes immediately; it solidified in about 15 min. Errors represent maximum deviation in six experiments.

† Agar layer assay method of Adams (ref. 2).

‡ Prepared as described by Swanstrom and Adams (ref. 3).

§ 3·0 ml. of bacterium suspensions, infected with enough phage to give confluent lysis (3·5 × 10⁴ of *T*1; 2·1 × 10⁶ of *T*2, *T*4 and *T*6; 2·1 × 10⁴ of *T*3 and *T*7; 5·3 × 10⁶ of *T*5) were mixed with 4·5 ml. of our melted agar, and poured on sterile Petri dishes. After overnight growth, 10·0 ml. of tryptone broth was added to each plate, and the agar was broken up and filtered fast through Whatman No. 2 paper in a size 3 Buchner funnel (losses were noted if it took too long to filter, therefore larger funnels should be used for larger volumes).

Let us first consider the formation of plaques on plates without 'bottom' agar. It is seen that the efficiency of plating for *T*1, *T*3 and *T*7 is the same as by the conventional assay over 'bottom' agar. However, the number of plaques for *T*2, *T*4, *T*5 and *T*6 formed on plates without 'bottom' agar is only approximately 50 per cent of that formed on plates with 'bottom' agar; therefore, in order to arrive at the correct value, plaque counts obtained by our method should be multiplied by two. The results are consistent if *E. coli* is in the same phase of growth.

Second, let us consider the yields of various phages by confluent lysis. The yields obtained on plates without 'bottom' agar were slightly better than the yields obtained on plates with 'bottom' agar. (However, our yields of phages prepared according to the method of Swanstrom and Adams[3] were lower than those reported by the original investigators.)

As the area for confluent lysis in a glass plate (Petri dish) is limited and as Petri dishes with large areas are not available, stainless steel trays (Volrath, size 17½ in. × 11⅝ in. × ¾ in.) with aluminium covers were used. Confluent lysis on such trays was conveniently achieved as follows: to 100 ml. of *E. coli* suspension, grown overnight in an incubator by shaking but without aeration, was added 100 ml. of tryptone broth, 40·0 ml. of special solidifying medium (the solidifying medium was similar to our assay medium as described before, except that it contained twice as much casamino-acids, nutrient broth and agar) and a proportionally larger number of phage (30 times the number used for confluent lysis per plates). The mixture was then poured on the trays and stored overnight at room temperature (25°). Then the soft agar was broken up and filtered on Whatman No. 2 paper through a large (size 6) Buchner funnel. The average yields (× 10¹³) obtained per tray were: 3·2 for *T*1, 3·8 for *T*2, 1·2 for *T*3, 2·0 for *T*4, 6·0 for *T*5, 4·3 for *T*6 and 1·1 for *T*7. These values are 25–50 times the yield obtainable in a normal size glass Petri dish without 'bottom' agar.

Summing up one can say that: (1) Routine assay of bacteriophage samples can be made on glass plates without 'bottom' agar, but a correction factor of 2 has to be taken into account for bacteriophages *T*2, *T*4, *T*5 and *T*6. (2) High yields of bacteriophages can be obtained when confluent lysis is carried out on glass plates without 'bottom' agar. (3) Confluent lysis can be adapted for large-scale bacteriophage production by carrying it out on large stainless steel trays.

PHYSIOLOGY

A New Concept of Temperature Regulation by Amines in the Hypothalamus

NEARLY ten years ago it was found[1,2] that adrenaline, noradrenaline and 5-hydroxytryptamine (5-HT) are present in relatively high concentrations in that part of the wall of the third ventricle known as the hypothalamus. Yet no definite function could be attributed to their presence in this diencephalic structure.

The hypothalamus is involved in the central control of a variety of important functions, one of which is concerned with regulation of body temperature. But what goes on in the hypothalamus to bring about this regulation? The experiments recorded here suggest that it is the release of adrenaline, noradrenaline and 5-HT.

The experiments are the outcome of two independent observations. First, that pyrogens injected into the cerebral ventricles[3,4] or directly into the anterior hypothalamus[5] of a cat cause fever and shivering, and second that, injected into the cerebral ventricles, adrenaline and noradrenaline abolish drug-induced shivering, whereas 5-HT has the opposite effect and evokes shivering. These effects, too, have been attributed to an action on the hypothalamus[6–8]. We have now shown that the injection of these amines through an implanted Collision cannula into the cerebral ventricles of an unanæsthetized cat also modify body temperature: adrenaline and noradrenaline lower, and 5-HT raises, the temperature.

To demonstrate the effect of adrenaline or noradrenaline, the body temperature has first to be elevated. This can be done by pyrogens. When a minute amount of pyrogen—about 1/1,000 of the dose effective on intravenous injection—is injected intraventricularly into an unanæsthetized cat the rectal temperature rises after a latency of about 1 h to a level of 2°–2·5° C above normal and remains elevated for several hours. The high temperature can then be brought down to normal, or to nearly normal, by an intraventricular injection of 50–100 μg of either adrenaline or noradrenaline. Within a few minutes the temperature begins to fall and the maximal fall is reached within about 45 min; then the temperature slowly climbs during the next 2–3 h until fever-level is again attained. When smaller doses of adrenaline or noradrenaline are injected intraventricularly at half-hourly intervals a reduction in temperature is maintained for longer periods. The injections of the catecholamines also cause cessation of the shivering produced by pyrogens.

To produce with 5-HT a rise in body temperature as well as shivering, 200 μg are injected intraventricularly into the unanæsthetized cat. Usually the rise occurs in two peaks. There is first a transient, relatively quick rise, which is followed within 1 h after the temperature has returned to normal by a second more gradual but prolonged elevation of up to 2° C. It is sometimes more than 20 h before the rectal temperature has returned to normal. When 5-HT is given during the pyrogen fever it appears to be even more effective. The intraventricular injection of 200 μg then causes an additional steep elevation of up to 1° C and it requires more than 30 h before the pyrogen–5-HT fever subsides.

The fever and shivering produced by 5-HT are affected in the same way by the intraventricular injection of adrenaline or noradrenaline as the fever and shivering produced by pyrogens. The temperature is brought down and shivering ceases.

The findings reported here lead to a new concept about the mechanisms involved in the hypothalamic regulation of body temperature. They suggest that normal temperature is maintained by a delicate balance in the release of adrenaline, noradrenaline and 5-HT in the hypothalamus, thus attributing an important physiological function to the occurrence of these amines in this part of the brain; this, however, may not be their sole function. The effect of adrenaline and noradrenaline in lowering body temperature is seen only when the temperature has first been elevated. The reason may be because these amines are continuously released in sufficient amounts in the hypothalamus to keep the temperature down, in the same way as their release is thought to prevent us from shivering continuously[9]. Additional adrenaline or noradrenaline applied artificially to this region, therefore, would have no action either on the temperature which is already down, or on shivering which is not present. A rise in temperature as well as shivering could then be visualized as the result of two mechanisms: an inhibition of the release of adrenaline and noradrenaline, and an initiation or augmentation of the release of 5-HT. Fever produced by pyrogens, that is, the fever of infectious diseases, may be brought about in just this way. In addition, pyrogens may render the hypothalamus more sensitive to the action of 5-HT, and there is the further possibility that pyrogens do not act solely through the hypothalamic amines and their release, but also mimic the effect of 5-HT.

Integration at an Inhibitory Interneurone: Inhibition of Renshaw Cells

THE spinal interneurones known as Renshaw cells have as their function the regulation of motoneurone activity: they appear to terminate on motoneurones directly inhibiting their firing[1], and to inhibit other inhibitory interneurones, thereby disinhibiting motoneurones and enhancing their discharge[2]. Because of this widespread involvement of Renshaw cells in the control of motor activity, the regulation of the firing of Renshaw cells themselves is of considerable interest. Since the discovery of these interneurones by Renshaw[3] and their subsequent detailed examination by Eccles, Fatt and Koketsu[1] and others, attention has centred on their excitation. However, it has been observed that Renshaw cells can be inhibited as well as excited by supraspinal stimuli[4], and an observation of Renshaw's[3] suggests that they can also be inhibited by antidromic stimulation of motor nerves. In view of the importance of Renshaw cells as the only clearly identified inhibitory interneurones in the spinal cord, we have investigated the influence of various types of stimuli on their discharge, and find that widespread inhibitory action contributes to the regulation of their activity.

All experiments were performed on acute decapitate cats; the carotid arteries were tied and vertebral arteries clamped. Artificial respiration was applied. In order to minimize movement all preparations were paralysed by intravenous injections of 'Flaxedil' (American Cyanamid Co.). Laminectomy was performed in the usual manner. In some preparations the dorsal roots on the side on which recording was to take place (ipsilateral side) were cut from *S2* to *L5* to prevent the entry of orthodromic impulses into the cord, and various leg nerves were dissected to make possible antidromic stimulation of motor nerves. With such preparations it was possible to test the effect on Renshaw cell discharge of natural stimulation of all limbs other than the ipsilateral hind limb and of antidromic stimulation of the ipsilateral motor nerves. For other experiments the ipsilateral dorsal roots were left intact and the ventral roots cut; on the contralateral side the ventral roots were cut, and leg nerves prepared for stimulation. This type of preparation was used for natural stimulation of the ipsilateral hind limb and electrical stimulation of contralateral muscle and cutaneous nerves.

Recording from Renshaw cells was extracellular, and was performed by means of glass micropipettes filled with 4 M sodium chloride and having a resistance of 1–2 Meg. Cells were found by tracking in the *L7*–*S1* region while stimulating either motor nerves or ventral roots, and were identified by their characteristic high-frequency response to a single antidromic shock[1,3]. Most cells were found within a few hundred microns of the dorsal root entry line and at depths between 2 and 3·5 mm. Once a cell was located and its pattern of discharge was determined, attempts were made to condition the discharge by electrical stimulation of various nerves and by natural stimuli applied to various parts of the body surface.

In agreement with Eccles, Eccles, Iggo and Lundberg[5], it can be stated that Renshaw cells can be activated by more than one muscle nerve, although often one nerve is dominant. In our experiments the discharge has consisted of up to 30 spikes, with a total duration of up to 60 msec. So far, we have been unable to inhibit this discharge by antidromic stimulation of any of the available muscle nerves (deep peroneal, flexor longus digitorum, plantaris, gastrocnemius-soleus, posterior biceps-semitendinosus, biceps anterior and semimembranosus). However, it has been possible to obtain powerful inhibition of the response by stimuli, such as squeezing and pinching applied to the various limbs. Such an inhibition is shown in col. 1 of Fig. 1. It can be seen that the inhibition is quite profound. The group of frames in *B* illustrates a typical occurrence, namely, that the inhibition becomes less powerful during a maintained stimulus. Strong inhibition has usually been obtained from the contralateral hind limb; in addition, inhibitory effects have often been seen as a result of stimulating the ipsilateral hindlimb, ipsilateral forelimb and tail. From the nature of the stimuli applied it is evident that much of the inhibition must be due to activity in cutaneous fibres. Experiments to determine the nature of the nerves involved are under way at present.

Column 2 of Fig. 1 shows that this inhibition is depressed by strychnine. Intravenous injection of 0·1 mg/kg strychnine sulphate resulted in some irregularity of the test discharge and occasional burst responses of the cell. It can also be seen in *B* of col. 2 that after strychnine the conditioning stimulus frequently resulted in slow waves, which were not, however, associated with discharge of the cell. Comparison of cols. 1 and 2 shows that in this instance the inhibition is almost abolished. Evidently this inhibition resembles, in its susceptibility to strychnine, the various post-synaptic spinal inhibitions that have been investigated (cf. ref. 6), and differs in this respect from various post-synaptic inhibitions at higher levels of the nervous system[7].

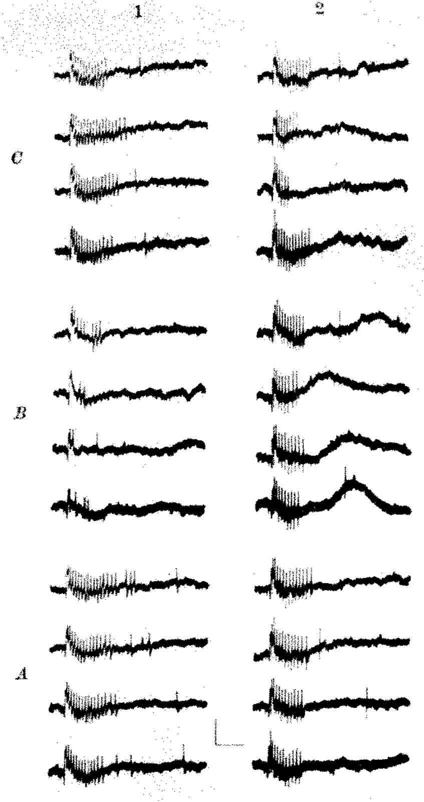

Fig. 1. Inhibition of Renshaw cell discharge. This cell was activated only by antidromic stimulation of posterior biceps-semitendinosus. The inhibition illustrated was obtained by squeezing of toes of the contralateral hind foot. In col. 1, reading from bottom to top, *A* shows control responses, *B* responses during squeeze of the toes, and *C* subsequent controls. Squeeze of the toes alone evoked no discharge. Col. 2 shows an identical series obtained 5 min after intravenous injection of 0·1 mg/kg strychnine sulphate. It can be seen that the inhibition is strongly depressed. The spikes in col. 2 are somewhat larger than those in col. 1, because the electrode moved closer to the cell. Upward deflexion negative. Time marker, 10 msec.; voltage calibration, 500 μV

It is clear from the results recorded here that Renshaw cells can be inhibited by means of segmental reflexes, both ipsilateral and contralateral, and by means of long spinal reflexes. Inhibition of inhibitory interneurones has been proposed in other regions of the nervous system[8,9], but our experiments provide positive evidence for inhibition of an interneurone the only known function of which is to inhibit motoneurones and other interneurones. Since depression of Renshaw cell discharge would result in release of motoneurones, these findings illustrate another pathway which can lead to disinhibition of spinal motoneurones. It is now apparent that the control of the recurrent collateral system which leads to inhibition and disinhibition of motoneurones[2,10] is even more complex than previously supposed.

It would seem reasonable to expect that inhibition of inhibitory interneurones, together with changes in excitatory drive, would play a part in the integration of motor activity. It is more economical to suppress an inhibition at its origin than to override it at its destination.

Prevention by Ascorbic Acid of Liver Glycogen Depletion in Endotoxin Intoxication

IT is well established that there is a striking depletion of liver glycogen in endotoxin intoxication, and insulin, glucose and lactate are relatively ineffective in increasing liver glycogen storage[1]. This depletion of liver glycogen is not necessarily due to epinephrine discharge or to circulatory disturbances attendant on intoxication, but it seems to be related to the accumulation of endotoxin in liver[2]. The characteristic prostration common to all animal species in the later stage of endotoxin intoxication seems to be related to this depletion of glycogen[2]. It is especially pronounced in adrenalectomized animals, and death results from hypoglycæmic deterioration with or without cramp. It is well known that pretreatment with cortisone prevents death[1]. Although the mechanism of glycogen depletion has been discussed in relation to inhibition of hepatic enzymes, especially succinic dehydrogenase[3], or to the effect on mitochondria leading to oxidative uncoupling[4], no conclusive evidence indicating special relations of endotoxin to these disturbances could be obtained. In this respect it has been shown that the effect of endotoxin in depleting liver glycogen in rabbits is much lessened in the hot summer season even in adrenalectomized animals[5]. It has therefore been suggested that the depletion of liver glycogen might be determined by the metabolic response of liver induced by the uptake of endotoxin in the hepatic reticuloendothelial cells. Here it was shown that saturation with ascorbic acid could ameliorate the depletion of liver glycogen in cold weather in which the susceptibility of the animal is markedly enhanced.

Albino rabbits weighing about 2·5 kg were used. They were maintained by 'Okara' (soy-beans curds waste 300 g with salt 0·5 g a day). Ascorbic acid (500 mg/day, mostly 'Hi-C' tablet of Takeda Chemical Industries, Ltd., Osaka) was mixed with 'Okara'. For attaining blood total ascorbic acid level at the saturation-level (about 1·2 mg/dl., DNP method), at least 4 days' administration was necessary. Experiments were performed both on intact and adrenalectomized animals in order to determine the effect of ascorbic acid saturation independent of glucocorticoids with which ascorbic acid has been claimed to be synergistic[6]. It has been repeatedly shown that adrenalectomized rabbits do not necessitate any replacement treatment and eventual existence of accessories can easily be checked by a water diuresis test[7]. Purified endotoxin (300 µg/kg of *Salmonella typhosa*, Difco) was administered intravenously after fasting overnight. Liver specimens for glycogen analysis were taken after 3 h under light 'Nembutal' anæsthesia (20 mg/kg, intravenously).

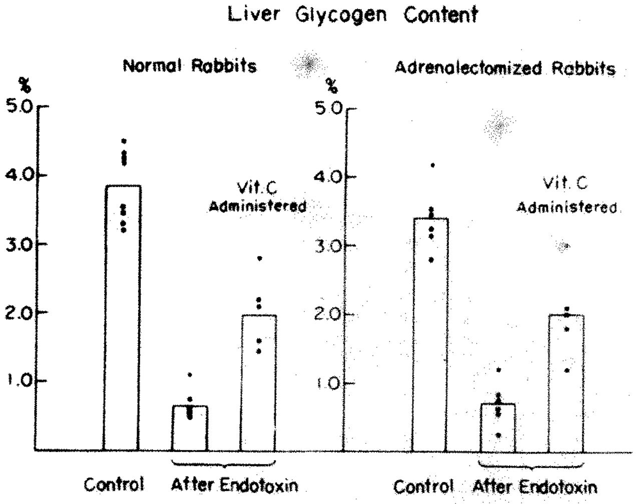

Fig. 1. Prevention of liver glycogen depletion due to endotoxin by ascorbic acid saturation (3 h after endotoxin)

As shown in Fig. 1, ascorbic acid saturation could markedly ameliorate the depletion of liver glycogen after endotoxin both in intact and adrenalectomized animals. With this the attendant hypoglycæmia was completely prevented and in intact animals the preceding initial hyperglycæmia due to epinephrine discharge[2] became marked and prolonged. Even adrenalectomized animals could tolerate the toxic dose used here (100 per cent lethal for adrenalectomized rabbits[2]). Thus the effectiveness of ascorbic acid in preserving liver glycogen independent of glucocorticoids could be substantiated. There was no indication that ascorbic acid consumption might be increased in endotoxin intoxication, since no appreciable changes in ascorbic acid content (total and reduced) in blood and liver occurred after endotoxin. Therefore, the effectiveness of ascorbic acid did not seem to be concerned with the supplement of ascorbic acid consumed. No gluconeogenetic effect[8] could be expected. Stabilization of hepatic metabolism by its antioxidative effect seemed to be the underlying mechanism. In cases of severe endotoxin intoxication the blood glutathione (GSH, after Brückmann and Wertheimer) became reduced (from about 30 to 20 mg/dl. 3 h after endotoxin inoculation). This was prevented with lessening of the intoxication by ascorbic acid saturation, just as the case with tolerant animals.

Saturation with ascorbic acid did not materially increase the ascorbic acid content of liver (13–18 mg per cent, total ascorbic acid) and yet could show the foregoing remarkable effect. In this respect, the observation by Fukuda and Horiuchi[9] in man that, with increasing saturation with ascorbic acid, the consumption of ascorbic acid estimated by the deficit in the daily urinary output compared with the amount ingested increased markedly might throw some light on this problem. In any event, significance of ascorbic acid saturation could be evaluated in endotoxin intoxication leading to hepatic glycogen depletion.

Alcohol and Evoked Potentials in the Cat

THE effect of alcohol on the electrical activity of the cortex and deep structures of the brain in various animals has been the subject of investigation of many workers, including Horsey and Akert[1] and Caspers[2]. There is a general agreement that this drug has a synchronizing effect on the spontaneous electrical cortical activity and, depending on the dose of alcohol, shows various degrees of reduction in frequency and decrease in amplitude. The underlying mechanism of this action is still in doubt. Kalant[3], in a comprehensive review, quotes Caspers[2] and furthers the idea that alcohol exerts its earliest effect at the level of the reticular formation and that the changes in electrical cortical activity are subsequent to the primary reticular depression. In this preliminary communication are presented results on the effects of alcohol on the evoked responses recorded from the reticular formation and cortex following stimulation of the sciatic nerve.

Acute experiments were carried out in 14 intact adult cats. Under ether anæsthesia the animals were tracheotomized and both femoral veins and one femoral artery cannulated. The animals were placed in a stereotaxic apparatus and electrodes (concentric needles) were stereotaxically placed through a burr hole into the mesencephalic reticular formation at intercollicular level (*F*; 2·5; *L*; 1·5; *H*; −2·5) according to the co-ordinates of Jasper and Ajmone Marsan[4]. Recording electrodes (chloride silver balls) were also located on the somatosensory cortex. The wound margins and pressure points were injected with local anæsthetic and the ether then discontinued. The animals were immobilized with 'Intocostrin' (Squibb), maintained on artificial respiration and kept warm under a heating pad. The sciatic nerve contralateral to the recording electrodes was cut before the ether was discontinued and the central stump stimulated electrically, 2–3 h post-operative, with single rectangular pulses of 7–9 V and 0·1–0·2 msec duration, delivered every 2 sec. The evoked potentials in the midbrain reticular formation and in the somatosensory cortex were simultaneously amplified and recorded on the face tube of a 502 dual beam 'Tektronix' oscilloscope. Photographs were taken with a 'Grass' kymograph camera. Arterial blood pressure was continuously monitored via the cannula inserted in the femoral artery which was connected to a mercury manometer. A 20 per cent solution of ethyl alcohol at a dose-level of 1 g/kg was slowly injected through one of the femoral cannulas which was used for this purpose only. The duration of injection was 2–3 min. Blood samples for the determination of alcohol-levels were drawn from the other femoral vein. Ethyl alcohol in the blood was determined enzymatically according to the method described in the *Sigma Technical Bulletin*, No. 330, April, 1963. Electrode placements were checked by histological examination of unstained frozen sections of the brain stem prepared as described previously[5].

Fig. 1 illustrates the effect of alcohol on the evoked potentials in the midbrain reticular formation and somatosensory cortex on stimulation of the sciatic nerve. Records of five superimposed frames were taken 2, 5, 30 and 60 min after the injection to compare with three sets of records taken as controls before the injection of alcohol. Blood samples were collected before and 5, 30 and 60 min after alcohol injection for determination of alcohol-levels. In the fourteen animals examined the following results were obtained: in nine experiments (Fig. 1, series *A*), the response from the somatosensory cortex was markedly depressed while the reticular response was only partially depressed 2 min after the administration of alcohol. The recovery process was evident 15 min after alcohol injection. Both responses recovered to some extent 1 h after alcohol treatment though the recovery of cortical response was retarded, in comparison with that of the reticular formation. In five other experiments (Fig. 1, series *B*), both the cortical and reticular responses were markedly suppressed two minutes after alcohol injection. However, in these animals the partial recovery of the reticular response was more marked than that of the somatosensory cortex 1 h after the injection of alcohol. In general, the cortex was more profoundly affected by alcohol than the reticular formation.

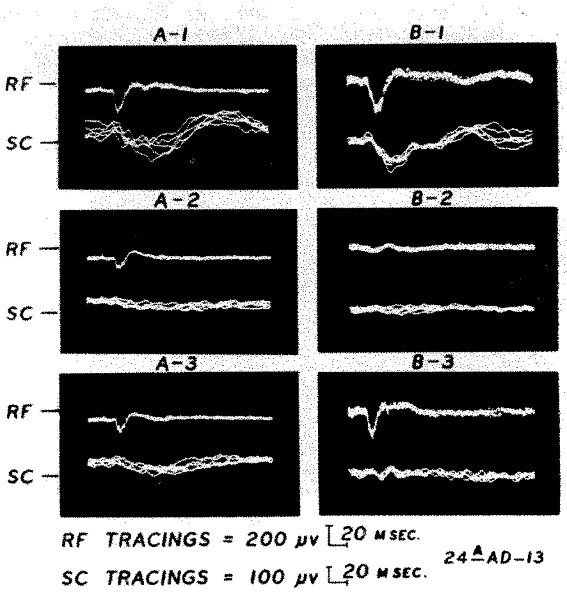

Fig. 1. Effect of alcohol on the evoked potentials in the reticular formation (*RF*) and somatosensory cortex (*SC*) on the stimulation of sciatic nerve. *A*-1, Control; *A*-2, 2 min after alcohol injection, a depression which was marked in *SC* and only partial in *RF*; *A*-3, 15 min after alcohol injection, onset of the recovery process which, however, was retarded in *SC*; *B*-1, control; *B*-2, 2 min after alcohol injection, marked depression of both responses; *B*-3, 1 h after alcohol injection, marked recovery in *RF* but very little in *SC*. Each response displays five superimposed traces. Upward deflexion indicates negativity

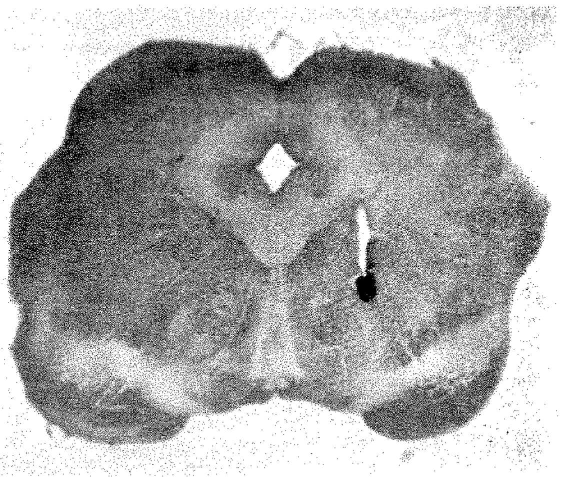

Fig. 2. Photomicrograph of an unstained coronal section of the midbrain. Track of electrode tip and a number of brain structures are clearly identifiable (× *c*. 4·75)

Control experiments were undertaken to rule out the effect of the volume of injection and of systemic changes introduced by blood pressure effects. Similar volumes of normal saline injected intravenously had no effect on blood pressure and the evoked potentials. The systemic effects of alcohol solution administered were checked by monitoring the blood pressure. About 50 sec after the injection, a moderate drop in blood pressure of about 15–20 mm mercury was observed. The initial value recovered in less than 2 min after alcohol administration. As a rule, the blood pressure values recuperated by the time the first record was taken after injection. In about 5–15 min, in most instances, the blood pressure would increase 20 mm mercury above the control value and remain so for the rest of the experiment. However, in others, the blood pressure recovered its control value within 30 min after injection. These changes in the blood pressure did not seem to influence the amplitude of the evoked potentials.

In Table 1 are shown the average levels of blood alcohol. It can be seen that 5 min after the administration of alcohol, when the responses were markedly affected, both in the reticular formation and the somatosensory cortex, the blood alcohol-levels increased from the average control value of 8 mg per cent to 123 mg per cent. These levels decreased gradually with time but were still high, as compared with the control values, after 1 h.

Table 1. BLOOD ALCOHOL-LEVELS BEFORE AND AFTER INTRAVENOUS ADMINISTRATION OF ALCOHOL (1 GM/KG)

Time after injection (min)	Control	5	30	60
Mg alcohol per 100 ml. blood	8·8 ± 3·8*	123·3 ± 27·2	107·2 ± 22·8	95·4 ± 24·4

* *S.D.*

Our experimental evidence does not confirm Caspers's contention[2] of a causative relationship for his findings of increased cortical excitability and depression of the reticular formation by ethanol. In no instance did we find increased cortical potentials. However, it should be pointed out that excitability and amplitude of evoked potentials are not necessarily correlated.

All the same, the striking observations presented here point to the fact that under our experimental conditions the cortex is affected more by ethanol than is the reticular formation. The time-course of recovery brings added evidence that alcohol exerts its effect more profoundly on the cortex. The recovery phase was not followed beyond the period of 1 h. It seems that the reticular formation and the cortex may have different thresholds of response to ethanol-levels.

PHARMACOLOGY

Anti-œstrogenic Effects of Bovine Pineal Glands

GONADOTROPIC activity of the pineal glands has been the subject of several extensive researches[1,2]. However, there is some discrepancy in the reported effects of pineal implants or pineal extracts on the œstrogenic manifestations. It is still uncertain whether the pineal gland contains both œstrogenic and anti-œstrogenic, antagonistically acting substances, or only one of them. Moreover, the reported results have been inconclusive as to the influence on pineal gonadotropic activity of such factors as species, age and sex of animals used as tissue donors[1-6].

In our experiments we decided to adopt the male frog spermatogenic test[7,8] for investigations of pineal anti-œstrogenic properties. Chorionic gonadotrophin ('Pregnyl', N.V. Organon-Oss, Holland) and the homogenized cow pineal glands (so adjusted with saline solution that 1 ml. contained 50 mg or 100 mg of fresh tissue) were used. In further experiments, extracts of cow pineal glands were also used. The extracts were prepared either according to the method described by Altschule[9] or by a method described by Bergmann[10] in such a way that, having made it up with saline solution, 1 ml. of extract was equivalent to 200 mg of fresh pineal gland. The preparations were injected into the dorsal lymph sac of male edible frogs (*Rana esculenta* L.). The homogenized pineal glands were applied 6 h, and the extracts 3 h, prior to the injection of chorionic gonadotrophin.

In the pilot experiments performed on 80 frogs no response, as regards spermatozoa excretion, was found in any one case after injection of bovine pineal gland. The results seem to indicate that the assayed pineal glands did not contain any œstrogenic agents.

The spermatogenic sensitivity of male frog is liable to change with the season of the year[11]. The experiments were carried in December 1962 and January 1963. Therefore, in the course of preliminary investigations it has been found that in conditions of the experiments the most suitable dose was 50 I.U. of chorionic gonadotrophin and the best response was received while examining the urine 6 h after the injection of the hormone.

In the first experiments we noticed that the bovine pineal glands taken from slaughtered adult cows inhibited very significantly the spermatozoa excretion in frogs. On the contrary, no effects were noticed after the application of the pineal glands collected from 2–4-week-old calves. At first, we were inclined to explain this observation as a matter of difference in the age. However, among the calves killed at that time at the local slaughterhouse there were male and female specimens in more or less equal proportions; among adult cattle there were only females. So male frog tests were also made separately with the pineal glands of male and female calves, and it was found that the pineal glands of female calves inhibited the frog spermatogenic reaction in a manner almost as intensive as those of the cows, while with the pineal glands of the male calves the reaction obtained was insignificant and it could not be confirmed statistically. In addition, when the pineal glands of males and females were combined together in a ratio 1 : 1 no inhibitory properties were found. Also the extracts by Bergmann and Altschule, when assayed for inhibition of the frog spermatogenic test, did not produce any clear, statistically provable effects, in spite of the fact that they were prepared using the pineal glands of cows.

Table 1. Effects of parenterally injected homogenized tissues and extracts from bovine pineal glands on spermatogenic response of the male frog, *Rana esculenta*, to chorionic gonadotrophin injection

* Compared with the control group No. 1 by the χ^2 method.

The results of the experiments are shown in the Table 1. For closer comparison, the number of frogs which rendered a positive spermatogenic response in a control group was taken as 100 per cent (relative per cent). In relation to that figure, the percentage of frogs reacting in the experimental groups was calculated (Fig. 1).

It seems that controversies on the subject of œstrogenic and anti-œstrogenic properties of the pineal gland met with in the available literature might be the result of not taking into consideration those peculiarities which are

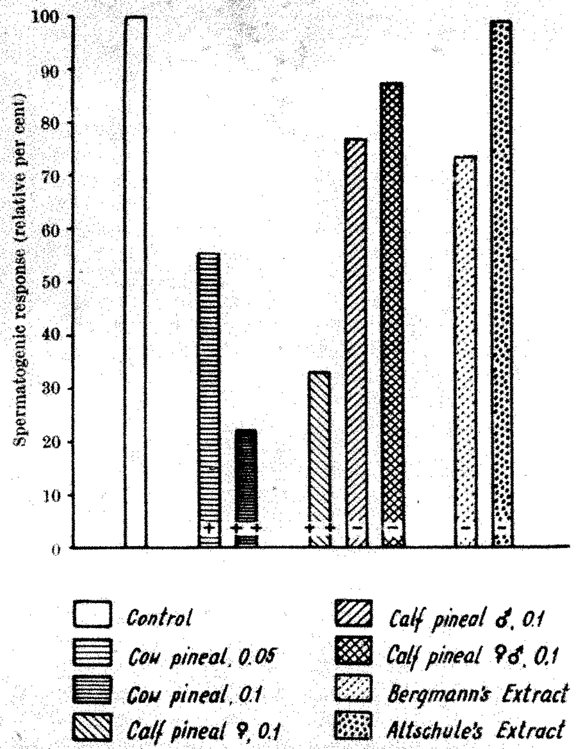

Fig. 1. Inhibition with pineal preparations of male frog spermatogenic reaction. ++, $P < 0·01$; +, $P < 0·05$; −, $P > 0·05$

connected with the sex of the animals used as pineal tissue donors. Moreover, it should be pointed out that after an application of 50 mg of cow pineal gland the inhibition of the frog reaction was nearly twice as weak as after a dose of 100 mg. It is to be expected that the described reaction of the inhibition of the frog spermatogenic test might be applied as a method of biological assay of the anti-œstrogenic properties of the pineal gland. Although several methods have already been suggested[1,2,10] for assaying the potency of pineal preparations, our method seems to have some advantages because of its simplicity, speed and cheapness.

Excretion of Neostigmine labelled with Carbon-14 in Urine

ALTHOUGH neostigmine (prostigmin) has been used for about thirty years for the treatment of myasthenia gravis, and later for the post-operative reversal of tubocurarine, relatively little seems to be known about the mechanisms involved in its metabolism and excretion. The inhibition of plasma cholinesterase has been used as a convenient indicator of neostigmine concentration, and it has been shown that after administration to dogs and to patients with myasthenia gravis, elimination of neostigmine depends on the dose and method of administration[1]. Some of these conclusions have been confirmed in more recent work where a colorimetric method was used for the measurement of neostigmine in urine[2]. Thus when neostigmine methylsulphate is given by intramuscular injection to patients with myasthenia gravis, about 50 per cent of the dose is excreted unchanged, whereas after oral administration little or no unchanged drug can be detected in the urine[2,6].

Further work in this laboratory has shown that a high proportion of each dose by intramuscular injection is excreted by myasthenic patients within 2 h. Confirmation that neostigmine is rapidly excreted was obtained by administration of neostigmine labelled with carbon-14 to rats, when up to 50 per cent of the dose was detected in the urine within 60 min of intramuscular injection. This evidence suggested that the rapid excretion of neostigmine might be due to renal tubular secretion.

Using the technique for estimating renal tubular secretion in the hen described by Sperber[7,8], we have found that after intramuscular injection of labelled neostigmine considerably more of the dose was excreted by the ipsilateral kidney than by the contralateral kidney (Table 1). Similar results were obtained when the drug was infused at a constant rate into the saphenous vein.

Table 1. RENAL EXCRETION OF NEOSTIGMINE BY THE HEN AFTER INTRAMUSCULAR INJECTION OF NEOSTIGMINE LABELLED WITH CARBON-14

Hen No.	Dose neostigmine (mg)	Percentage of dose recovered in urine from each kidney		Duration of collection (min)
		Ipsilateral	Contralateral	
1	0·667	39·7	5·7	90
2	0·333	65·2	16·1	90
3	0·333	59·8	7·7	120
4	0·333	57·4	6·5	135

The renal tubular transport of *N'*-methylnicotinamide (NMN) and of a number of other quaternary nitrogen compounds has been shown to be inhibited by the basic cyanine dye, 1'-ethyl-3,6-dimethyl-2-phenyl-4-pyrimido-2'-cyanine chloride ('Cyanine 863')[3–5]. Experiments in which labelled neostigmine was injected in single doses and by continuous infusion into the saphenous vein of the hen have shown that the apparent tubular excretion factor is substantially reduced by prior or concurrent administration of 'Cyanine 863'.

We conclude from this evidence that when neostigmine is injected a substantial proportion of the dose is eliminated by renal tubular secretion.

The urine collected in the experiments on hens has been examined by paper chromatography and electrophoresis; most of the carbon-14 is present as neostigmine but there is also evidence of *m*-hydroxyphenyltrimethylammonium, a metabolite of neostigmine previously reported by Scott *et al.*[6].

We thank the Distillers Co., London, for a grant in support of this research from which one of us (B. H. T.) is in receipt of a maintenance grant. The 'Cyanine 863' was kindly supplied by Dr. L. G. S. Brooker of Eastman Kodak Co., New York.

Platelet Damage induced in Plasma by Certain Fatty Acids

THE implication of lipids in the production of hypercoagulability of the blood has been recognized for a number of years. For example, the presence of certain lipid fractions has been shown to facilitate blood clotting *in vitro*, and hypercoagulability has been demonstrated in blood taken from human subjects after a meal of high fat content[1-3]. It has been shown recently that the addition of certain fatty acids to plasma accelerates the clotting time[4], and of especial interest are observations by Poole and Connor that small quantities of long-chain saturated fatty acids, but not unsaturated congeners, evoke a marked hypercoagulability of blood in the thrombus-generator[5-7] This instrument, originally described by Chandler, utilizes a revolving loop of plastic tubing into which blood is placed. The clot produced by this procedure has been shown to closely simulate thrombi occurring in human thromboembolic disease; that is, with a white head of platelets and leucocytes and a fibrin tail[8,9].

We have recently reported that rabbit plasma contains a factor which causes platelet damage as manifested by release of platelet histamine and serotonin, and that the plasma factor, though calcium dependent, acts even in the presence of a high concentration of heparin[10]. We have, therefore, examined the effects of fatty acids on platelets in plasma rendered incoagulable by heparin.

Platelet-rich plasma was prepared in siliconed glass centrifuge tubes as described previously[11]. Fatty acids were dissolved in distilled water with an excess of sodium hydroxide, and the *p*H was adjusted to about 7·8 with hydrochloric acid. Heparin was added to a final concentration of 80 μg/ml., followed by fatty acid solution. The tubes were then recalcified and incubated for 30 min at 37° C. Platelets were removed by centrifugation at 1,200*g* for 30 min at room temperature. The histamine and, in some tubes, serotonin content of the supernatant plasma were then measured fluorometrically[12,13] and compared with the amine content of platelet-rich plasma.

Table 1. EFFECT OF FATTY ACIDS ON RELEASE OF HISTAMINE FROM RABBIT PLATELETS UNDER VARIOUS CONDITIONS*

Condition	Histamine release (control = 1·0)†
Caprylic acid (50–250 μg/ml.)	1·0 (0·9– 1·3)
Myristic acid (25 μg/ml.)	2·2 (1·3– 2·9)
Palmitic acid (25–250 μg/ml.)	1·3 (1·0– 1·9)
Stearic acid (10 μg/ml.)	3·0 (1·9– 5·1)
Stearic acid (25 μg/ml.)	5·9 (3·0– 9·8)
Stearic acid (50 μg/ml.)	6·5 (3·6–10·4)
Arachidic acid (1–25 μg/ml.)	5·2 (2·4– 8·0)
Behenic acid (1–10 μg/ml.)	3·2 (2·4– 4·4)
Oleic acid (25–250 μg/ml.)	1·0 (0·8– 1·2)
Linoleic acid (100–250 μg/ml.)	1·1 (1·0– 1·3)
Linolenic acid (100–250 μg/ml.)	1·2 (0·9– 1·4)
Stearic acid (50 μg/ml.), no calcium	0·8 (0·6– 1·2)
Stearic acid (50 μg/ml.) cold (5° C)	0·7 (0·5– 1·2)
Stearic acid (25 μg/ml.) albumin solution	0·8 (0·6– 1·1)

* Fatty acids were incubated with rabbit platelet-rich plasma in the presence of heparin (80 μg/ml.), as described in text.

† Figures for histamine release denote ratio of percentage available histamine released in experimental tubes divided by histamine released in control tube (plasma + heparin + calcium) at 37°. Figures in parentheses denote range. Serotonin release (not shown) was about the same as histamine in all tubes measured.

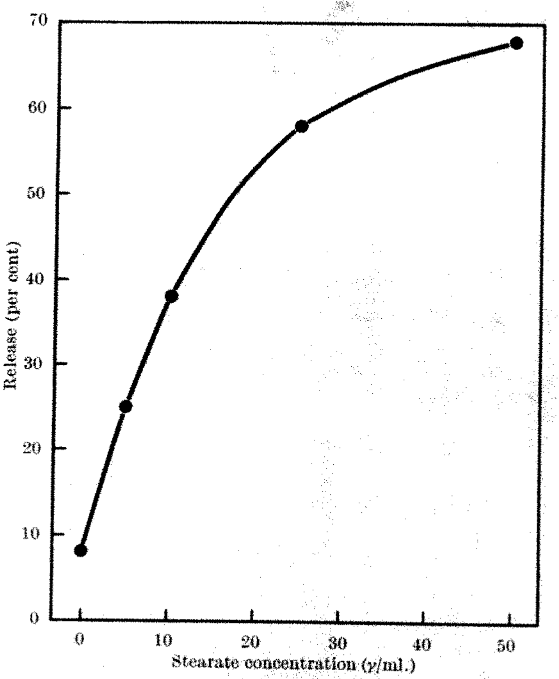

Fig. 1. Effect of various concentrations of stearic acid on release of platelet histamine

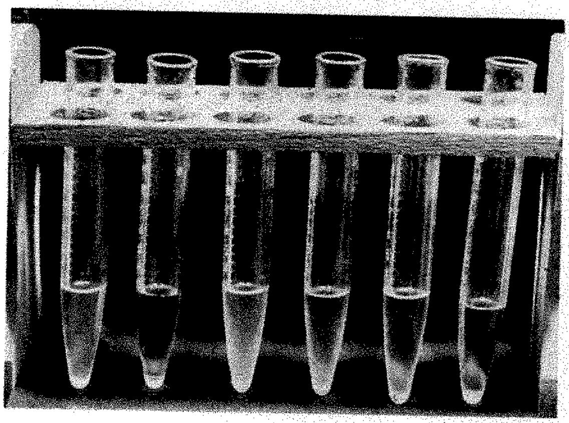

Fig. 2. Effect of stearic acid (25 μg/ml.) on rabbit platelets. Tubes were incubated and centrifuged as described in text. Left to right: (1) plasma—no stearate; (2) plasma + stearate—no calcium; (3) plasma + stearate; (4) plasma (50 per cent) + bovine serum albumin (50 per cent) + stearate; (5) plasma (25 per cent) + bovine serum albumin (75 per cent) + stearate; (6) bovine serum albumin + stearate. All tubes contained heparin (80 μg/ml.) and (except for No. 2) excess calcium ion. Figures for histamine release were: (1) 10, (2) 5, (3) 60, (4) 38, (5) 25, (6) 8 per cent

As shown in Table 1, a marked release of platelet histamine occurred in tubes to which small quantities of stearic, arachidic, or behenic acids were added, while relatively little or no release occurred with lower molecular weight saturated fatty acids or with unsaturated fatty acids, even at much higher concentrations, indicating a considerable degree of specificity in the mechanism. Fig. 1 illustrates the effect of various concentrations of stearic acid. As shown in Table 1, no histamine release occurred in the absence of calcium ion or in tubes kept in the cold (5° C). The involvement of a plasma factor is suggested by the finding that stearic acid did not act on washed platelets suspended in buffered bovine serum albumin solution (Table 1). Fig. 2 illustrates the effect of stearic acid on platelets suspended in various combinations of plasma and bovine serum albumin solution. In the presence of plasma, stearate, and calcium ion, most of the platelets have adhered to the vessel wall, but platelet damage, as estimated visually or by histamine release, is minimal in the absence of any one of these factors.

The platelet damage described here occurs even in the presence of sufficient heparin to block the action of thrombin on fibrinogen or on platelets. The fatty acid effect thus may act through an early stage of the coagulation mechanism, one not affected by heparin. The mechanism possibly involves the action of Hageman factor, thought to be responsible for the effects of fatty acids on whole blood coagulation[6,7,14]. The heparin-insensitive mechanism of this type of platelet damage may be of importance in the ætiology of white thrombus formation and hypercoagulability. The experimental system described in this communication could provide a technique for the study of certain early coagulation steps.

IMMUNOLOGY

Hæmolytic Complement and Serum Bactericidin

In a previous communication[1], serum bactericidin was related to a clotting factor extracted from fibrin. Several properties of this bactericidin are known to be shared by hæmolytic complement, such as inactivation by heating at 56° C for 30 min and removal by filtration through Seitz filter pads. Complement, like bactericidin, is absent from uncoagulated cell-free plasma[2]. Further investigations comparing the two serum activities were undertaken.

Both guinea pig and human sera served as sources of complement. Experiments were set up as follows. To fresh serum dilutions made up in 0·2 ml. of 0·9 per cent sodium chloride were added 0·2 ml. of 0·75 per cent sheep erythrocyte suspensions. Such cells had to be sensitized with immune hæmolysin when guinea pig serum was used, whereas with human serum this was not necessary. Tubes were incubated in a 37° C water bath for 1 h and read for complete hæmolysis. The smallest amount for this reaction or unit of complement was 0·005–0·01 ml. of guinea pig serum or 0·01–0·02 ml. of human serum. The difference between the action of guinea pig and human serum was explained by the finding that human serum normally contained both complement and sheep hæmolysin. Heating at 56° C for 30 min destroyed complement but left behind antibody which would bring about sheep cell lysis with guinea pig serum. The antibody could not be removed by repeated washings of the sensitized cells with saline. Its titre was determined by lysis with guinea pig serum (2 units of complement) as well as agglutination with anti-human globulin. Identical results were obtained. With most sera the minimal reactive dose was 0·005 ml. Normal human serum also contains sheep red blood cell agglutinins but of a much lower titre. A high titre of such agglutinins, as present in the sera of patients suffering from infectious mononucleosis, did not affect the hæmolysin titre.

No difference in the action of human and guinea pig complement was observed. Neither one was able to bring about the lysis of human Rh-positive cells sensitized with low-titred antibody, which strongly reacted with anti-human globulin. Like bactericidin, both were inactivated by lytic factor and heparin[1]. Only 0·01 ml. of potent lytic factor preparation was required to block the action of 2 units of complement. The reaction was immediate. It could be reversed by the addition of excess complement. Barium sulphate in 10 or 25 mg quantities absorbed in 10 min all complement from 0·1 ml. of human or guinea pig serum but did not affect serum bactericidin. Both complements also differed from bactericidin in thermostability at temperatures below 56° C, as reported previously[1].

Sera of a number of patients suffering from a variety of infectious and organic diseases were analysed for complement and sheep hæmolysin. Considerable reduction in either one factor or both was noted in many instances, but no consistent pattern emerged. High bactericidin-levels often coincided with reduced complement activity. Guinea pig serum, though rich in complement, had no bactericidin.

From the results of this investigation as well as previous studies[1,3] it would seem that clotting factor extracted from fibrin, *C* reactive protein, serum bactericidin, and hæmolytic complement share a chemical grouping that arises immediately prior to or during fibrin formation. Indirect evidence[4] points to a steroid glucuronide. It would also appear most likely that their differences in physico-chemical and physiological properties are due to association with different proteins.

Specificity of Isoantisera against Leukæmic and Thymic Lymphocytes

This communication concerns the specificity of isoantisera prepared against leukæmic and against thymic lymphocytes of *AKR* mice, as determined by immune cytolysis[1-3]. Discovery of a strong antigen associated with the thymic lymphocytes of *AKR* mice is also reported. A preliminary report has been made[4].

For immune cytolysis of *L*4946 leukæmic lymphocytes of *AKR* mice, the small-scale assay system previously described in detail[2] was used. The only change was use of 100,000 cells per assay tube. Essentially the same cytolysis system was used for thymic lymphocytes, except that absorbed hamster serum at a final concentration of 10 per cent was used as source of complement[3].

Isoantisera were prepared by injection of leukæmic and of thymic lymphocytes of *AKR* mice into mice of strains *C57BL*/6 and *C3HeB*/*Fe*(ref. 3). The cytolytic potencies of each of the four isoantisera were determined against *L*4946 leukæmic cells and against thymic lymphocytes (Table 1). Cytolytic potency is expressed as 100/cytolytic titre, where the cytolytic titre is the final concentration of isoantiserum (per cent) giving 50 per cent cytolysis of cells present in an assay tube. Specificity is expressed as the ratio of cytolytic potencies[5]; it refers to specificity against cell types, and has no direct bearing on the presence or absence of specific tumour antigens.

The relatively high potency of *C57BL*/6 isoantisera for cytolysis of *L*4946 leukæmia (Table 1, *A*) correlates well with the complete resistance of *C57BL*/6 mice to intraperitoneal transplantation of *L*4946 cells. The low potency of *C3HeB*/*Fe* isoantisera for cytolysis of *L*4946

Table 1. Specificity of Isoantisera against Leukæmic and Thymic Lymphocytes

Isoantisera prepared against	Cytolytic potency for cytolysis of *L*4946 leukæmia (*AKR*)	Thymic lymphocytes (*AKR*)	Specificity against *L*4946 leukæmia
A. Isoantisera prepared in *C57BL*/6 mice.			
*L*4946 leukæmia	78	4	19·5
Thymic lymphocytes	24	450	0·053
Specificity against *L*4946 leukæmia	3·2	0·0089	366
B. Isoantisera prepared in *C3HeB*/*Fe* mice.			
*L*4946 leukæmia	4	340	0·012
Thymic lymphocytes	3	450	0·0067
Specificity against *L*4946 leukæmia	1·33	0·76	1·8

leukæmia (Table 1, *B*) also correlates well with the semi-sensitive state of *C3HeB/Fe* mice to implantation of the *L*4946 tumour, the LD_{50} being 200,000 cells. In contrast, the LD_{50} of *L*4946 cells injected intraperitoneally into *AKR* mice, in which this tumour originated, is approximately 11 cells[6]; so far we have been unable to demonstrate cytolytic antibody in this situation.

The isoantiserum prepared in *C57BL/6* mice against *L*4946 leukæmia (top line, Table 1, *A*) showed a 78/4 or 19·5-fold higher specificity in its reaction against *L*4946 cells relative to its reaction against thymic lymphocytes. In contrast, the *C57BL/6* isoantiserum to thymic lymphocytes (second line, Table 1, *A*) showed a specificity of 0·053. The ratio of the specificities of these paired isoantisera (*C57BL/6* anti-*L*4946 leukæmia and *C57BL/6* anti-thymic lymphocytes), as tested against the same paired cell types (*L*4946 leukæmia and thymic lymphocytes), was 19·5/0·053 or 366. The overall specificity of 366 for the two isoantisera prepared in the resistant *C57BL/6* mice (Table 1, *A*) contrasts strongly with the overall specificity of 1·8 for the two isoantisera prepared in the semi-sensitive *C3HeB/Fe* mice (Table 1, *B*). This difference is mainly due to the unexpected reverse in specificity of the *C3HeB/Fe* isoantiserum to *L*4946 cells (top line, Table 1, *B*), as compared to the specificity of the *C57BL/6* isoantiserum to *L*4946 cells (top line, Table 1, *A*).

The allele H-2^b present in *C57BL/6* mice differs from the H-2^k or H-$2^{k'}$ allele of *AKR* mice, while *C3HeB/Fe* mice possess the same allele as *AKR* mice[7-9]. Moreover, tumour cells isologous to a given mouse strain carry antigens corresponding to the H-2 allele of that strain[7,8]. For these reasons, isoantisera prepared in *C57BL/6* mice are relatively potent against *L*4946 cells which carry antigens corresponding to the H-2^k or H-$2^{k'}$ allele of *AKR* mice, while the isoantisera prepared in *C3HeB/Fe* mice and also tested against *L*4946 cells are barely active.

Presence of one or more strong antigens on the surface of *AKR* thymic lymphocytes is revealed by the strong cytolytic potencies shown against these cells by isoantisera prepared in *C3HeB/Fe* mice (Table 1, *B*), which were obtained despite compatibility in the H-2^k or H-$2^{k'}$ allele. Detailed information regarding these antigens can be deduced from the results given here. This will be published elsewhere when further experiments have been completed.

PATHOLOGY

Sampling of Cell Material from Human Tumours by Aspiration Biopsy

CELL material which is aspirated from human carcinomas through a fine needle consists largely of plugs of epithelial cells with admixture of interstitial fluid and variable amounts of blood. In earlier investigations[1-3], the epithelial component was isolated by centrifugation for quantitative enzymatic analysis. The activity of dipeptidase and of acid and alkaline phosphatase enzymes was determined in cells aspirated from mammary and prostatic carcinomas. These values were compared with results from analyses of epithelial plugs aspirated from benign mammary and prostatic lesions.

Since patients experience relatively little discomfort from aspiration biopsy with a fine needle, repeated biopsies are readily tolerated. The method should therefore be useful for examining the biological behaviour of tumour cell populations at different stages of the disease. This communication reports use of aspiration biopsy for examining the viability of cancer cell populations during radiotherapy.

A Luer–Lock syringe with a special handle[4] which allows a one-hand grip was used together with a stainless steel needle approximately 8 cm long and 0·7 mm in outer diameter (22 gauge). Use of this fine needle minimizes admixture of blood. Biopsy is performed as follows. The skin is washed with antiseptic solution and the tumour is fixed with one hand in a favourable position for needle biopsy. The needle is then introduced into the tumour area. In order to obtain sufficient material, especially from fibrotic tumours, the needle must be moved back and forth in the tumour four or five times. When the specimen has been aspirated, the pressure in the syringe is allowed to equalize before the needle is withdrawn from the tumour area. The material in the needle is carefully expressed into 0·2 ml. of sterile Simms's balanced salt solution in a 2-ml. centrifuge tube. A cell suspension is prepared by gentle pipetting with a sterile Pasteur pipette. Aliquots are taken for cell counts in a Bürker hæmocytometer chamber and for vitality tests, using the membrane permeability for eosin *Y* or lissamin green dyes as indicators of death of the cells[5]. The remainder of the suspension is sedimented by centrifugation at 20*g* in a refrigerated centrifuge at 4° C and resuspended in tissue culture medium for short-term tissue culture investigations (results to be published later).

Fig. 1 shows the percentage of permeable cells in cell populations aspirated from two tumours on consecutive days during radiation therapy. A conventional X-ray apparatus (200 kV) was used and the skin doses were recorded. The filled circles indicate death of cells in aspirate from a lymph node metastasis (diam. about 1 cm) of a poorly differentiated squamous carcinoma. The open circles denote cell death in aspirate from a tonsillar lymphoblastic lymphoma (diam. about 3 cm).

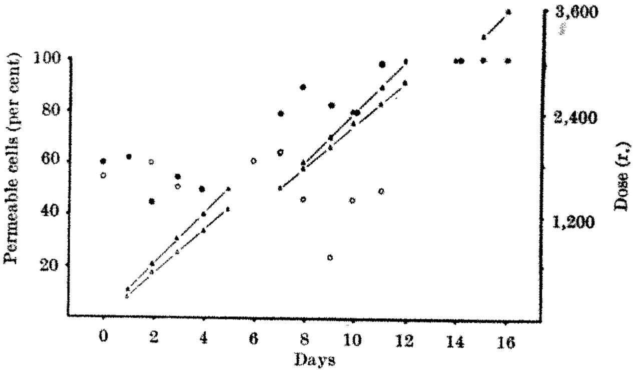

Fig. 1. Percentage of permeable cells in tumour populations aspirated on consecutive days of radiotherapy. ●, Lymph-node metastasis from squamous carcinoma; ○, lymphoblastic lymphoma; triangles, irradiation dosage

Clinically the metastatic squamous carcinoma proved to be fairly resistant to irradiation and persisted after treatment, whereas the lymphoma was radiosensitive and disappeared on the eleventh day.

In apparent contrast, Fig. 1 shows that death of cells in aspirate from squamous cell carcinoma increased during radiotherapy, the maximum being reached during the last days of treatment. No measurable increase of death of cells was found in the radiosensitive lymphoma, even on the eleventh day, when the tumour had almost completely disappeared.

The results hitherto obtained do not indicate if the findings in this latter tumour were attributable to selective removal of damaged cells from the tumour site during irradiation, before death of cells could be registered by means of dye permeability tests. However, it seems pertinent to mention that cells aspirated from tumours which clinically are regarded as radiosensitive (for example, lymphoblastic lymphomas, seminomas, or some low-differentiated carcinomas or sarcomas) display in smear preparations or suspensions marked decrease of mutual adhesiveness and behave as individual free cells. Contrary behaviour is shown by highly differentiated carcinomas and sarcomas. The possibility must therefore be taken into account that during radiotherapy the cell populations of clinically radiosensitive tumours may become mobilized as a result of low mutual adhesiveness[6] before death of the cells can be demonstrated by dye tests.

BIOLOGY

Silurian Echinoid Pedicellariæ from New South Wales

So far pedicellariæ are unknown in echinoids older than Carboniferous. The Silurian echinoid with which pedicellariæ occur has been recorded by Sherrard[1], and is now catalogued as *F*8554 in the University of New England Palæontological Collection. It was collected from Vallance's Hill, Portion 177, Par. Namina, some 12 miles south-east of Yass, New South Wales, from rocks regarded as Ludlovian in age.

The echinoid is the mould of an imbricate lepidocentroid in which the corona has disintegrated leaving an accumulation of isolated plates, radioles, maxillæ and (?) teeth. Although both secondary limonitic staining and the coarseness of the enclosing matrix to some extent obscure finer detail, the remains of eight pedicellariæ are visible among the debris.

The pedicellariæ (Fig. 1) are all small, 0·34–0·4 mm in height, with the base reaching a maximum diameter of 0·16 mm. They possess narrow elongated blades more than two-thirds their height. All are three-valved, typical tridentate pedicellariæ. No details of apophyses can be seen, nor can any stalks be identified.

Knowledge of Palæozoic echinoid pedicellariæ is confined almost solely to the studies of Geis[2], who described isolated pedicellariæ collected from Carboniferous strata of Texas, Illinois and Missouri. Jackson[3] also has recorded a single pedicellaria associated with a specimen of *Meekechinus elegans* Jackson from the Permian of Kansas. Geis found not only globiferous and tridentate types, but also ophicephalous pedicellariæ, which Mortensen[4] attributed to the Lepidocentroida by analogy with those of living echinothuriids. In passing it must be noted that Durham and Melville[5] were unaware of the occurrence of Palæozoic ophicephalous pedicellariæ when they proposed an echinoid classification in which the sub-classes were based virtually on the presence or absence of these[6].

The seeming absence of ophicephalous pedicellariæ in the Silurian lepidocentroid reported here, is, perhaps, to be expected. Their absence in living cidaroids suggests that they were as yet undeveloped in lepidocentroids when the cidaroids arose from this order, probably in the Devonian. Regnéll[7] has described some isolated radioles from the Upper Silurian of Gotland as *Silurocidaris clavata*. These, however, cannot be taken as indicating the Silurian occurrence of the Cidaroida, for they lack the microstructure characteristic of representatives of this order.

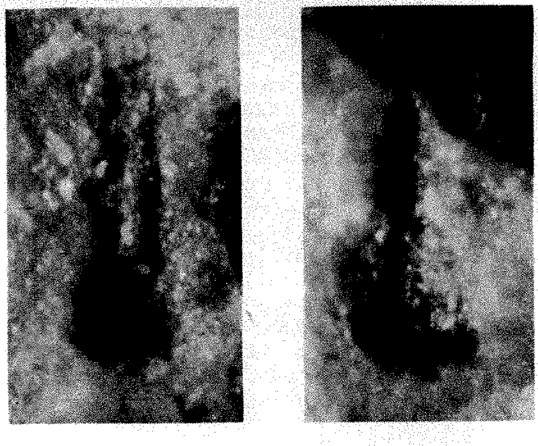

Fig. 1. Unretouched photographs of moulds of two tridentate pedicellariæ from the Silurian of New South Wales (× 100)

Döderlein[8] has deduced from the examination of pedicellariæ of living echinoids that the tridentate type is the primitive parental form from which other types have been differentiated. While an argument based on such premises lacks sure foundation, support for Döderlein's conclusion is now provided by the oldest echinoid pedicellariæ from the fossil record.

This communication establishes the early origin of simple tridentate pedicellariæ within the Echinoidea, and suggests that the possession of pedicellariæ may be a necessary attribute of this echinoderm class.

Glucose-6-phosphate Dehydrogenase and Potassium Concentration in Sheep Erythrocytes

THE relationship of glucose metabolism to electrolyte-levels in erythrocytes has been the subject of numerous investigations.

Evans and King[1] established that the potassium concentration (K^+) in sheep erythrocytes was under genetic control and could be greatly altered by the presence of one or another of a pair of alleles at one locus, the gene for high potassium being recessive to that for low potassium. The Australian Merino belongs predominantly to the low-potassium group and its erythrocytes have potassium-levels even lower than those of the low potassium groups in British breeds[2]. New-born lambs of all breeds examined have high erythrocyte potassium-levels, which decrease gradually and reach adult values when the animals are about 2 months old[3].

Wright *et al.*[4], investigating glucose metabolism in young lambs, found that as potassium-levels decreased with the age of the animal, so the rate of uptake of oxygen of their erythrocytes in the presence of glucose also became lower, but anaerobic glycolysis did not show any similar trend.

Significantly higher uptake of oxygen, $^{14}CO_2$ and lactate production were observed with erythrocytes from high-potassium Southdown sheep when they were compared with low potassium Merinos[5].

In earlier experiments[6] on Peppin Merinos erythrocyte glucose-6-phosphate dehydrogenase (G-6-PD) activity has been found to be very low, about 5 per cent of normal human red cell values. Subsequent tests on Merino and British cross-bred animals, however, yielded somewhat higher values. It seemed of interest, therefore, to investigate the relationship between (K^+) and glucose-6-phosphate dehydrogenase activities in the erythrocytes of different breeds.

The present tests were done on animals of different sexes and ages chosen at random from: (1) a closed flock of Southdown sheep; (2) inbred families of Peppin Merinos. The experimental techniques used for the estimation of potassium[3] and glucose-6-phosphate dehydrogenase[6] in erythrocytes were described earlier. Experimental details and results are given in Table 1.

Table 1. CORRELATION BETWEEN ERYTHROCYTE POTASSIUM CONCENTRATION AND GLUCOSE-6-PHOSPHATE DEHYDROGENASE ACTIVITY

Breed	Potassium type	No. of animals	(K^+) (m.equiv./l. red blood cell)		G-6-PD (Δ $O.D._{340}$/min/ml. red blood cell at 20° C)*		Correlation coefficient
			Mean	Standard deviation	Mean	Standard deviation	
Southdown	low	36	18·84	4·50	0·328	0·082	0·480†
Southdown	high	19	78·86	10·38	0·329	0·102	0·323 N.S.
Merino	low	56	9·68	2·41	0·248	0·068	0·437‡

* G-6-PD activity was estimated spectrophotometrically by the rate of NADP reduction in a system containing glycylglycine buffer *p*H 7·6, 40 mM; $MgCl_2$, 16·7 mM; NADP, 77 μM; G-6-PD, 8·3 mM; hæmolysate, 0·2 ml.; water to 3·0 ml. final volume.

† $P < 0·01$.

‡ $P < 0·001$.

The correlation coefficients calculated for (K^+) and G-6-PD activity are significant in the low-potassium groups of both the Southdown and the Merino sheep ($P < 0·01$, and $P < 0·001$, respectively). The correlation in the high-potassium Southdown group is not statistically significant.

The levels of G-6-PD activity were very similar in the two potassium groups of the Southdown animals. The erythrocytes of Merino sheep, however, seemed to have a lower level of this enzyme than those of the British breed. A Student's *t* test performed on the enzyme values obtained from all 55 Southdown and 56 Merino sheep showed the difference to be significant at the 0·1 per cent level.

These results differ from those of Budtz-Olsen *et al.*[7], who recently failed to demonstrate G-6-PD activity in both high- and low-potassium sheep erythrocytes and concluded that sheep were deficient in this enzyme. The methods used for the determination of enzymatic activities were, however, different from those used in our experiments.

I thank Mrs. J. Williams for the statistical analysis of the experimental data.

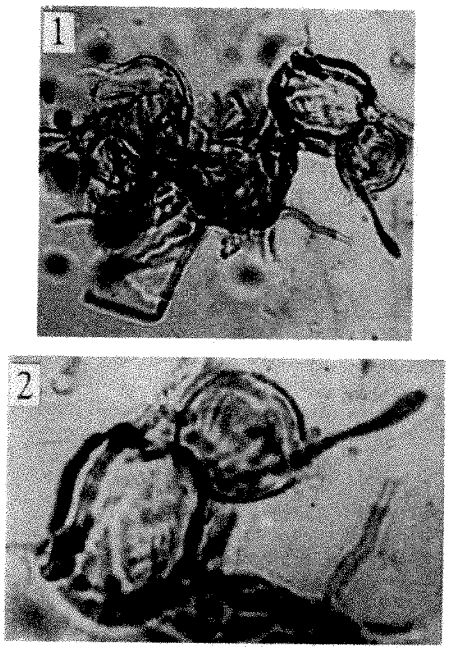
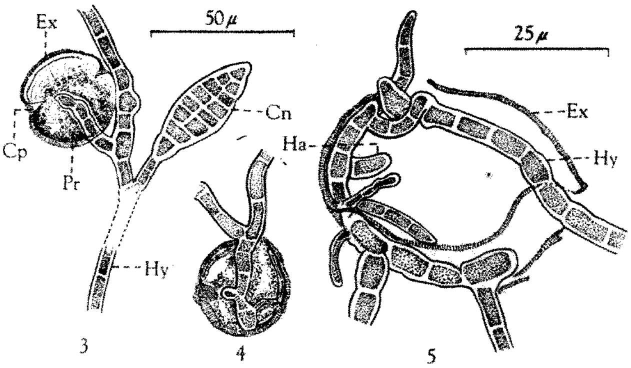
Fungal Infection on the Pollen Grains of *Schizanthus pinnatus* Ruiz and Pav.

ALTHOUGH fungal infections of the floral heads have often been observed in a number of plants, the nature of such infections on the pollen grains has usually escaped attention. The examination of the fungal relations of pollen grains is a new field of research, and may be deemed to be of importance in considerations of pollen viability and the dissemination of parasitic fungi.

Fungal infected floral heads of *Schizanthus pinnatus* (Solanaceae) were collected from the nursery of the National Botanic Gardens, Lucknow, in March, 1963. The infected flowers were crushed in lacto-phenol, warmed over a flame, and stained with cotton blue, for microscopic examination. Pollen grains of *Schizanthus* are provided with three germinal furrows, and with highly vacuolated protoplasmic contents. The infection of these pollen grains (Figs. 1–5) is caused by *Alternaria* sp., in various ways. The hyphæ enter the pollen at the furrows, ramify in the protoplasm, and sometimes pass out through the other furrows. The region of the hyphæ inside the pollen grains ('intrapollinous hyphæ' as opposed to 'extrapollinous hyphæ') produce,



Figs. 1 and 2. Photomicrographs showing the fungal (*Alternaria*) infection on the pollen of *Schizanthus pinnata* (Fig. 1, × 285; Fig. 2, × 570)



Figs. 3–5. Line diagrams of Figs. 1 and 2. *Cp*, Colpus; *Cn*, conidia; *Ex*, exine of pollen; *Ha*, haustoria; *Hy*, hyphæ; *Pr*, protoplasm of pollen

'haustoria' which possibly helps the fungus to absorb food materials from the pollen.

The 'intrapollinous' hyphæ remain either vegetative or form conidia and lie either along the pollen wall or at the centre of the grain. The fungal infection seems to cause the dissolution of the protoplasm either partially or completely. Similar infections have been observed in the pollen of *Cocos nucifera* and also other cultivated plants.

We thank Prof. K. N. Kaul, director of the National Botanic Gardens, Lucknow, for his advice.

Embryos derived from Callus Tissue Cultures of the Wild Carrot

INDEPENDENT regeneration of root or shoot primordia is common in higher plants. However, the simultaneous, integrated development of both primordia from a single small mass of meristematic cells is found almost exclusively in ovular embryos. We have observed the development of structures bearing both these primordia, from callus tissue cultures of the wild carrot, *Daucus carota* L. These structures closely resemble *in situ* pro-embryos and embryos both morphologically and in their pattern of development.

The callus was obtained by aseptically culturing root tissue on a semi-solid medium designed by Caplin and Steward[2]. It was sub-cultured through several transfers prior to use. Embryos were obtained by transferring single 4–6 cm pieces of callus to a liquid version of the culture medium and rotating these in an apparatus similar to that described by Steward *et al.*[3]. Ten days after transfer, some cultures had produced 50–100 of the structures pictured in Fig. 1. All stages of development, from compact nearly spherical bodies 0·2 mm in diameter to those with projections resembling cotyledonary nodes and radicles, were observed at this time. Subsequent development of these pro-embryo-like structures is pictured in Fig. 2. Green cotyledon-like appendages and typical roots have formed. If these plantlets were removed from the liquid nutritive medium at this stage and transferred to a moist agar substrate containing only the mineral components of the culture medium, development continued along normal seedling patterns and young wild carrot plants were produced.

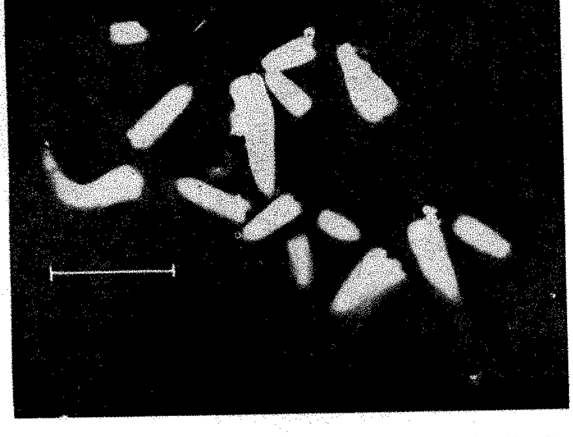

Fig. 1. Embryo-like structures taken from a ten-day-old liquid culture of wild carrot callus. Cotyledonary-node-like projections are present at one end of nearly all structures. The two largest structures each have a well-developed root tip. Scale, 1 mm

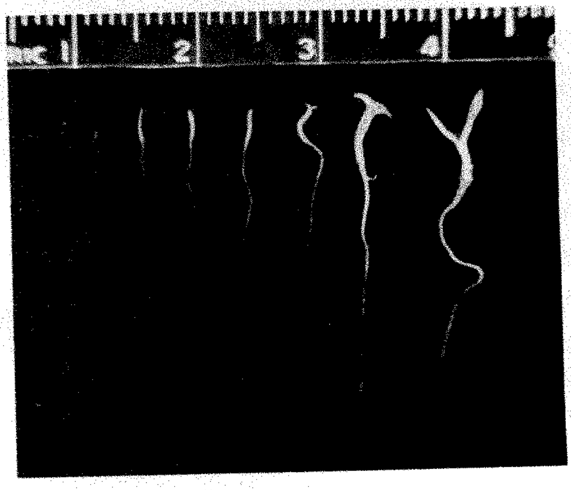

Fig. 2. Wild carrot plantlets which have developed from the structures shown in Fig. 1 after 2–3 weeks' further culture. Scale units, cm

The origin of these embryo-like structures is uncertain. They appeared freely suspended in the culture medium at the earliest stage at which they could be distinguished from the debris. They may have been formed at the surface of the callus mass or from clumps of free-cells which were commonly observed in these cultures. Their development is distinctly different from the plantlet formation described by Steward *et al.* in cultures of the commercial carrot[1]. These authors reported that first, minute tissue masses were formed in cell aggregates of freely-suspended cells. When these 'nodules' reached a certain size, inner cells became lignified and 'tracheid-like' and became enclosed by a sheath of 'cambium-like elements'. Root primordia formed in the cambial region. Shoot primordia did not appear until rooted 'nodules' were transferred to stationary agar media.

In our cultures, the smallest recognizable organized structure (about 0·1 mm diameter) consisted of densely packed small meristematic cells. Even these small cell masses appeared to be polarized, with the long axis of the cells oriented in one direction. No lignified vascular elements and no cambial sheath were formed. As the size of these structures increased they became cylindrical (Fig. 1) with long axis parallel to the long axis of the cells. Root primordia appeared at one end of the elongated pro-embryo-like structure while green cotyledon-like appendages developed simultaneously at the opposite end. Normal appearing roots, with a root cap, root hairs and occasional lateral rootlets were then formed By the time the roots were several cm long, the region corresponding to the hypocotyl of a seedling was approximately 1 cm long and strongly red-pigmented as is often true of the hypocotyl of seedlings of this species. Extensive development of the shoot apex and true leaves was not observed in rotating liquid cultures but appeared in all plantlets soon after transfer to stationary cultures.

The basic difference between the phenomenon reported here and that reported by Steward *et al.*[1] seems to be in the time of development of the polarizing forces which are thought to direct differentiation and axial development of the root and shoot meristems. In our cultures this polarity seemed to exist in the earliest stages. This leads to a very orderly development in which root and shoot poles developed simultaneously and in a manner similar to that of normal embryogenesis. In the case studied by Steward *et al.*[1], the organization of root primordia was delayed until a sizable mass of cells was formed by relatively disorganized growth. Steward[4], in fact, stresses the role of isolation of the inner cells of the 'nodules' from the nutrient medium as an important step in the initiation of orderly growth. The initiation and subsequent development of the root primordia were more typical of branch roots which are pericyclic in origin than it was of the radicle-primary root sequence of embryos. Shoot development apparently did not occur until rooted 'nodules' were subjected to the unilateral influence of gravity.

From the results of this work it would seem that the essential conditions for embryogenesis can be duplicated *in vitro*. The opportunity, provided by these tissue cultures, to examine the early stages of the organization of co-ordinated root-shoot systems may eventually permit the identification and elucidation of the controlling forces of embryogenesis.

Production of Pectic Enzymes by *Rhizoctonia solani* and Orchid Endophytes

Rhizoctonia solani has frequently been isolated from roots of the purple marsh orchid, *Orchis purpurella*, with which it may form a normal mycorrhizal symbiosis. Such endophytic strains and others isolated as pathogens from diseased crop plants often show symbiosis to *O. purpurella* protocorms in culture tests[1,2]. In the absence of any knowledge of the pectolytic potentiality of orchid endophytes a development of this investigation has been a comparative examination of the production of pectic enzymes by various *Rhizoctonia* strains *in vitro*.

The fungi used included pathogenic *R. solani* strains *Rs* 6 from potato and *Rs* 10 from rice (respectively parasitic and symbiotic to *O. purpurella* protocorms) and two typical orchid symbionts *R. repens* (*Rr*) from *O. purpurella* and *R. goodyerae-repentis* (*Rgr*) from *Goodyera repens*. Cultures were grown at *p*H 5·6 in static liquid media containing 1 per cent glucose or apple pectin as carbon source, 0·35 per cent casein hydrolysate, 0·05 per cent yeast extract, 0·1 per cent KH_2PO_4, 0·05 per cent $MgSo_4 7H_2O$ and trace elements. With all the strains tested, growth and sclerotial formation followed a similar pattern on the two media, pectin being only slightly less good a carbon source than glucose.

Culture filtrates were collected daily and assayed at predetermined *p*H optima for the enzymes endopolygalacturonase (PG)[3], endopolymethylgalacturonase (PMG)[3] and protopectinase. PG and PMG activity was determined viscometrically and expressed in arbitrary enzyme units per volume of culture filtrate using a modified form of the method of Roboz, Barratt and Tatum[4]. Protopectinase activity was expressed as a maceration index using Brown's method[5].

Pectic enzyme production was negligible on glucose, but comparatively large amounts were secreted throughout the growth period on pectin media. Typical results for actively growing cultures on pectin are given in Table 1.

Table 1. PECTIC ENZYME ACTIVITY OF CULTURE FILTRATES OF ACTIVELY GROWING *Rhizoctonia* STRAINS ON A PECTIN MEDIUM

Strain symbol	*Rs* 6	*Rs* 10	*Rr*	*Rgr*
Age of culture (days)	4	4	7*	4
Mycelium dry wt. (mg)	119	90	67	109
PG activity (units)	15·8	41·5	427·6	5·0
PMG activity (units)	1·7	5·4	42·7	1·2
Maceration index	6·3	3·9	6·1	3·7

*Growth-rate of *R. repens* was lower than that of other strains.

It can be seen that all the strains have a potentiality for the secretion of each of the pectic enzymes tested, in quantities unrelated to their symbiotic or parasitic character. In particular, the pectic enzyme potential of *R. repens* is surprisingly high. It has not yet been possible to investigate enzyme production by orchid endophytes *in vivo*, but it seems unlikely that parasitic and symbiotic activity can be discriminated on the basis of pectic enzyme production alone. The symbiotic host endophyte complex must incorporate factors controlling the production of pectic enzymes which otherwise might give rise to a pathogenic condition. It is suggested that these factors arise only as the result of the interaction of the metabolic systems of the two partners.

So far as is known, this is the first demonstration of pectic enzyme production by symbiotic mycorrhizal fungi.

MICROBIOLOGY

β-D-1,6-Glucanase in *Streptomyces*

According to Reese *et al.*[1], β-D-1,6-glucan rarely occurs in Nature, yet many fungi are able to produce an enzyme capable of hydrolysing it. Production of β-D-1,6-glucanase by *Streptomyces* has not been reported.

Previously[2,3] we reported that a newly isolated micro-organism produced lutease (β-1,6-glucan-6 glucanohydrolase) when grown in a Czapek medium containing peptone and higher-molecular-weight luteose instead of sucrose. This latter substance is a β-D-1,6-glucan prepared from mucilage which was produced from glucose by *Penicillium aculeatum* Raper and Fennell var. *apiculatum* Abe strain No. 2282 isolated by us from soil[4].

Since the details of taxonomic position of lutease-producing micro-organism were as yet uncertain, although the strain seemed to belong to *Streptomyces* species, morphological and cultural characteristics of the strain were examined. From the characteristics, that is, straight aerial hyphæ (with smooth surface spore), water-green aerial mycelium, medium to strong proteolytic action, *Streptomyces* strain No. *OP*–4–5 was identified as belonging to *Streptomyces griseus*.

Tests were made to search for lutease production in *Streptomyces* species. Among the 89 species, 92 strains, of *Streptomyces* tested, *Streptomyces griseus* N.I.H.J.13, *Streptomyces griseus* N.I.H.J.107, *Streptomyces parvus* N.I.H.J.115, and *Streptomyces niveoruber* N.I.H.J.413, produced lutease more or less by previous culture for 48 h at 30° C in a Czapek medium containing peptone and higher-molecular-weight luteose instead of sucrose on a shaker. The lutease production of these 4 strains was defined by lutease activity assayed at each culture time. Results are shown in Figs. 1 and 2. Two strains of

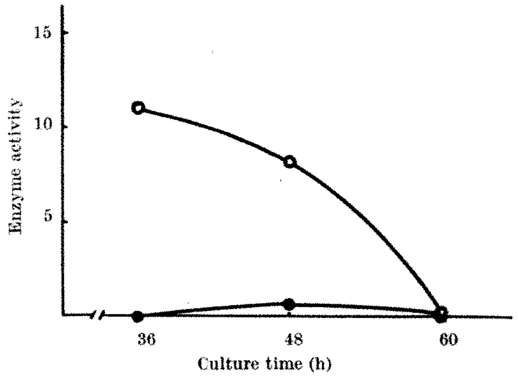

Fig. 1. Production of lutease by *Streptomyces griseus* N.I.H.J.13, and *Streptomyces griseus* N.I.H.J.107. ○, *S. griseus* N.I.H.J.13; ●, *S. griseus* N.I.H.J.107. Each strain was cultured in Czapek medium containing 0·2 per cent peptone and 0·5 per cent higher-molecular weight luteose instead of sucrose at 30° C on a shaker. The assay method of lutease activity (ref. 2) was used in the same way

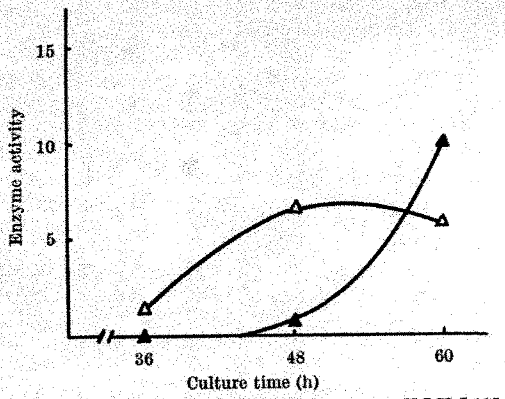

Fig. 2. Production of lutease by *Streptomyces parvus* N.I.H.J.115, and *Streptomyces niveoruber* N.I.H.J.413. △, *S. parvus* N.I.H.J.115; ▲, *S. niveoruber* N.I.H.J.413

Streptomyces griseus tested produced lutease, but the production by *Streptomyces griseus* N.I.H.J.107, was very low. Lutease activity produced by *Streptomyces griseus* strain No. *OP*–4–5 was 25·7 after culture for 36 h culture under the same conditions. It may be that *Streptomyces griseus* generally produces lutease when grown in a medium containing higher-molecular-weight luteose. According to Ettlinger *et al.*[5], *Streptomyces parvus* also belongs to *Streptomyces griseus* series. Although the 4 strains produced lutease, the amount was smaller than that of the enzyme produced by *Streptomyces griseus* strain No. *OP*–4–5 which was isolated by us.

We thank Dr. H. Umezawa and Dr. Y. Okami, of the National Institute of Health, Tokyo, for supplying *Streptomyces* species and for their advice.

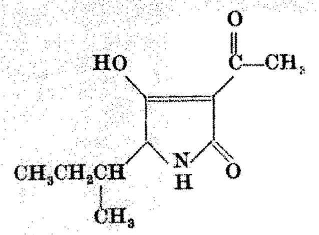
VIROLOGY

Antiviral Activity of Tenuazonic Acid

TENUAZONIC acid (I) was first isolated by Rosett *et al.*[1] from culture filtrates of various strains of *Alternaria tenuis*. The recent report[2] of antitumour activity of tenuazonic acid prompts us to report our results with this mould metabolite. During an antiviral screening programme culture filtrates of an *Aspergillus* were found to inhibit the cytopathic effect of measles virus in *HEp*2 (Moore) cell cultures (and to exhibit antibacterial activity referable to penicillins). An antiviral compound which later was shown to be tenuazonic acid was isolated from these filtrates. Isolation was assisted by measles and poliovirus plaque tests.

The *Aspergillus*, strain *F*1404, had been isolated from a Venezuelan soil sample and fermented aerobically at 26° C for 4–5 days in a medium containing glucose, soy-bean meal, brewers' yeast, and sodium chloride. Crude tenuazonic acid was first obtained from such culture filtrates by 'Darco' adsorption, followed by elution with aqueous acetone and *n*-butanol extraction of the concentrated eluate. Later the crystalline copper salt and the pure liquid acid were isolated following the procedure of Rosett *et al.*[1] The chemical and physical properties of our acid and its derivatives were shown to be virtually identical with those reported by the English group[1,3] and with those of an authentic sample synthesized from ethyl *L*-isoleucinate and diketene using the method developed by Lacey[4].



I

Tenuazonic acid as the sodium salt inhibited the cytopathic effect of a wide spectrum of viruses. In addition to the original measles activity, the compound showed an antiviral effect in the range of 500 to 100 μg/ml. against enteroviruses (poliovirus *MEF*-1, *ECHO*-9, Coxsackie B_1), respiratory viruses (*para*influenza-3 (*HA*-1), Salisbury *HGP*), vaccinia, herpes simplex *HF*, and '*B*' virus. The compound was inactive in tissue culture against polyoma virus (Stewart and Eddy) and in the mouse against Asian influenza (*Jap.* 305), rabies (*CVS*), and Friend leukæmia. Sodium isotenuazonate (prepared by alkaline isomerization of the parent compound) was inactive against poliovirus but proved to be approximately as active as sodium tenuazonate against *ECHO*-9, *para*influenza, vaccinia, herpes simplex, and measles viruses.

Table 1. SODIUM TENUAZONATE VERSUS POLIOVIRUS *MEF*-1 IN AGAR DIFFUSION

Concentration (μg/ml.)	Zone diameter (mm) Activity	Zone diameter (mm) Toxicity
5,000	50	20
3,570	44	20

Table 1 shows the results of a polio agar diffusion test with sodium tenuazonate. The antibiotic was placed on filter disks on agar overlay and the zones were measured. A good dose response can be seen. Table 2 shows the concentration of sodium tenuazonate required to reduce the number of plaques formed by a representative group of viruses by at least 50 per cent.

Table 2. ABILITY OF SODIUM TENUAZONATE TO INHIBIT VIRUS PLAQUE PRODUCTION UNDER AGAR OVERLAY

Virus	μg/ml.* showing at least 50 per cent plaque reduction
Measles (Enders)	500
Vaccinia	500
Herpes simplex (*HF*)	160
ECHO-9	500
'B' virus	500

* Tested at half-log dilutions of 5–0·05 mg/ml.

Single doses of sodium tenuazonate, administered to dose-groups of 25 or 30 18–20-g *ICR* male mice, gave LD_{50} values of 125 mg/kg ± 10 (*S.E.*, Miller-Tainter) intravenously, 150 ± 10 intraperitoneally, 145 ± 20 subcutaneously, and 225 ± 20 orally. Cynomolgus monkeys tolerated a single oral dose of 50 mg/kg; doses of 100, 150, and 300 mg/kg *PO* gave survivors/treated ratios of 4/6, 2/6, and 1/6, respectively. Antiviral activity in monkeys has not been studied.

Sodium tenuazonate was found to be essentially inactive against bacteria (31 strains), yeasts (48 strains), and *Trichomonas vaginalis in vitro*. Against the 200-F strain of *Entamoeba histolytica* it proved to be markedly active *in vitro*, but only slightly active by mouth in cæcally infected rats.

Inclusion Bodies in *Dahlia* infected with Dahlia Mosaic Virus

THE formation of inclusion bodies of various types in virus-infected plant tissue is not infrequent. Such inclusion bodies are located either in the cytoplasm or, less commonly, in the nucleus[1].

In a previous paper[2], it was noted that the inclusion bodies formed in leaf epidermal cells of *Dahlia variabilis* Cav. infected with dahlia mosaic virus were located in the cytoplasm. Recently, examination of epidermal tissue from immature leaves has shown the presence in the nuclei of inclusion bodies of a type exactly similar to that found in the cytoplasm (Fig. 1). Furthermore, stages have been observed which strongly suggest that the inclusion body, after formation in the nucleus, is extruded into the cytoplasm (Figs. 2 and 3).

The inclusion body at this stage is 2–7μ in diameter, spherical, and apparently composed of an outer membrane enclosing a matrix in which are many granular bodies. It is possible that the membranous portion is not confined to the outer surface but may take the form of a reticulum in which the granules are located.

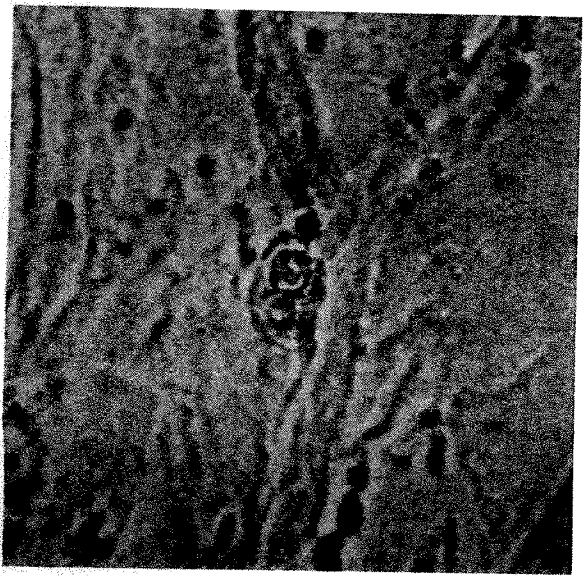

Fig. 1. Nucleus enclosing a large inclusion body and smaller nucleolus (× 1,000)

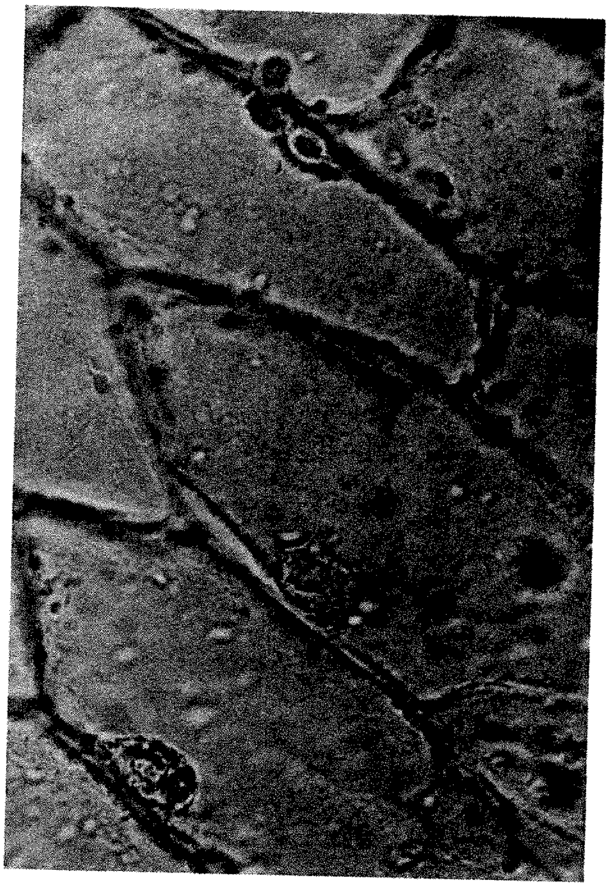

Fig. 2. Inclusion bodies in (bottom) or near (top) the nucleus (× 1,000)

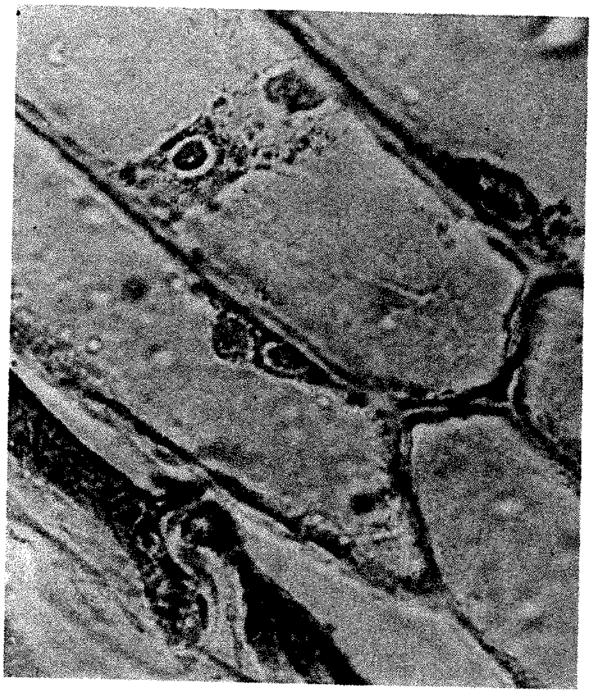

Fig. 3. Inclusion bodies apparently emerging from nuclei (× 1,000)

The granules stain positively for ribonucleic acid and protein, while the membrane stains with Nile blue and may therefore contain phospholipid. Present indications are that the virus aggregates or replicates at several sites in the nucleus, probably corresponding to the granules.

These early stages in development are at present under investigation and may provide a useful indication of the mechanism of virus replication in the plant.

CYTOLOGY

Negatively Stained Lipoprotein Membranes

IN a recent communication Finean and Rumsby[1] have cast doubt on the reliability of the electron microscopic image obtained from negatively stained preparations of lipoprotein membrane structures (myelin, mitochondria, microsomes and red cell ghosts). Although we agree with their remarks about the need for caution in interpreting such electron micrographs, it is felt that further comment is necessary concerning some of the published literature[2,3] mentioned by them.

During the examination of sub-cellular components[2] a comparison was made between: (*a*) unfixed negatively stained preparations; (*b*) preparations fixed with either formaldehyde or osmium tetroxide, followed by negative staining; and (*c*) conventional thin sections[4,5]. Owing to the low osmolarity of the 1 and 2 per cent phosphotungstate used for negative staining, it was found to be necessary with structures sensitive to the osmotic pressure of the surrounding medium (for example, nerve ending particles, mitochondria) to fix the particles before negative staining in order to prevent obvious disruption. Liver mitochondria are particularly sensitive. With osmotically insensitive structures (for example, myelin fragments) similar results were obtained with fixed and unfixed material. However, exposure of unfixed material to the hypotonic phosphotungstate was kept as brief as possible. Under these conditions negatively stained preparations were found to possess structural features directly comparable with those of positively stained sectioned material as is clearly illustrated in the published micrographs[2].

We consider that inferences drawn from the X-ray diffraction study of air-dried material in the absence of a suitable negative staining agent do not necessarily apply to material dried in the presence of a negative stain. As with positive staining, the mechanism of negative staining is not fully understood, but it is probable that the electron dense material sets in a rigid 'glass' and dries more rapidly than does the biological material in the absence of the stain. This may well prevent some of the changes seen in material air-dried in the absence of negative staining from occurring.

Turning to the question of biological and artificial membranes studied by several authors[3,6], it has been suggested by Finean and Rumsby that the patterns observed after treatment with saponin are a result of changes occurring during the final stages of drying. As indirect evidence that this is not so is the observation that the birefringence of a lecithin–cholesterol dispersion in water is rapidly lost by the addition of a dilute (1 per cent) saponin solution, thus indicating a loss of the lamellar structure in the myelinics. Bangham and Horne reported at a recent meeting of the British Biophysical Society that the same basic structures could be seen in lecithin–cholesterol preparations treated with saponin after treatment with buffered osmium and then air-dried. It was suggested that although dehydration effects may still be present, the separation of lipid components to form the same basic patterns under these conditions was unlikely.

The observations of Lucy and Glauert[7], on the increase in length of the helical components with time in mixtures of lecithin, cholesterol and saponin, lend support to the view that these structures are produced in the liquid phase.

X-RAY diffraction studies of the air drying of myelin have included experiments in which myelin fractions from brain were dried in the presence of phosphotungstate. It is clear that this material does contain layering which electron microscopy of thin sections shows to be similar to that of the normal preparation, but it also includes additional layered systems which are significantly different. The drying of such specimens was probably appreciably slower than that achieved in the preparation of negatively stained specimens for electron microscopy, but the possibility of the existence of more than one type of layering in the latter preparations is clearly indicated.

Our suggestion concerning the remarkably regular hexagonal system seen in negatively stained preparations of saponin-treated cell membranes, lecithin–cholesterol dispersions, and cholesterol monolayers was that this particular geometrical arrangement might have been formed during the final stages of dehydration. The observation that the birefringence of lipid droplets is decreased by the addition of saponin certainly indicates an interaction in the hydrated state but not necessarily a loss of lamellar structure nor the formation of hexagonal or helical systems. Comparisons of the swelling of brain lipid pellets in distilled water and in saponin solutions (up to 50 per cent saponin) have shown very similar sequences of changes in X-ray diffraction patterns, all patterns so far being readily interpretable in terms of a layered structure. Similar diffraction sequences have also been observed using sodium cholate, sodium deoxycholate, or sodium dodecyl sulphate, all of which will dramatically reduce the birefringence of lipid droplets in the way that saponin does, but which have not yet been shown to form hexagonal or helical systems. It would seem to us that the state of hydration at which such systems are formed remains unknown.

GENETICS

Sex Ratios under Natural Selection

SEVERAL workers[1,2] have shown the numerical equality of two sexes (that is, a 1 : 1 sex ratio) to be selectively favoured in relation to the parental effort involved in the rearing of offsprings to maturity. More recently, Kalmus and Smith[3] have argued in support of the adaptive superiority of this ratio on the basis of such considerations as those of hybridity, recombination potential and the level of inbreeding as influenced by sex ratio variations. However, their arguments are not valid in general and at best seem to apply only to the monogamous species. In fact, widely deviant sex ratios are reported to occur in the natural populations of both polygamodiœcious and gynodiœcious species[4,5], and Lewis[5] has suggested that sex ratio adjustments frequently through a preponderance of females help ensure reproductive economy combined with the maintenance of certain hybridity optima in such species. In a few theoretical examples analysed by Shaw[6], such adaptive changes were examined in the presence of certain specific sex-ratio factors. In this note a model of differential selection for an autosomal recessive in the two sexes is utilized to show that maximum levels of heterozygosity (say 0·50 where gene frequencies $p, q = \frac{1}{2}$) could be attained with variable sex ratios, a result in disagreement with the view of Kalmus and Smith[3].

Consider, for example, a large random mating population with the following adaptive values at an autosomal locus:

	Genotype		
	AA	Aa	aa
in females	1	1	$1 + s$
in males	1	1	$1 - t\ (s, t > 0)$

Then, for $s > t > s/1 + 2s$, there is stable equilibrium with heterozygosity:

$$H = \frac{(s-t+2)\ (s-t)\ [s+t-\sqrt{(s-t+2)\ (s-t)}]}{\frac{1}{2}\ (s+t)^2}$$

and sex ratio (♀ : ♂) $= \frac{s}{t}$

Thus, for a constant sex ratio, say k, and $H_\infty \doteq 0{\cdot}50$, t is uniquely determined by putting $\frac{dH}{dt} = 0$, which gives:

$$t = \frac{8\ (k-1)}{(1+k)^2 - 4(k-1)^2}$$

Table 1 gives some numerical examples to show that as sex ratio departs from 1 : 1, selection has to become increasingly intense in order to give $H = 0{\cdot}50$ at equilibrium.

Table 1

Sex ratio (k)	1·0	1·1	1·2	1·3	1·4	1·5
t	0	0·18	0·33	0·49	0·62	0·76

A similar study at a sex-linked locus shows that differential selection can establish deviant sex ratios in a population with its hybridity levels even higher than those expected under no selection. Likewise with a model of cytoplasmic sex-ratio factor by Watson[7], it is easily shown that in the case of gynodiœcious that carry in effect male sterility governed by cytoplasmic factors, sex ratio variations do not affect the amount of heterozygosity.

The recombination potential of any population or species as a whole need not always be lower in case of unequal sex numbers although the effective population size is indeed maximum with a 1 : 1 sex ratio. In fact, a relative excess of homogametic sex, which is perhaps often true[5], should result in a greater recombination potential in species like *Drosophila* with no crossing-over in the males. As regards some amount of inbreeding resulting from an unequal sex ratio, it might be that an intermediate rather than maximum amount of outbreeding would be adaptively better in view of a compromise between the requirements of immediate fitness and long-term flexibility[5,8]. Thus, there appears to be no *a priori* reason to assume an adaptive value associated with a 1 : 1 sex ratio as a general rule, and natural selection of various forms can, in fact, regulate this important factor too, like many others such as breeding habit, population number, mode of dispersion or even karyotypic features of a genetic system[9].

Somatic Reduction of Chromosome Number in a *Ribes* Hybrid following Treatment with *para*-Fluorophenylalanine

The *Ribes* breeding programme at East Malling involves considerable use of widely different species as donor parents. From some of these species, genes of potential economic value are being transferred to cultivated varieties of currant and gooseberry (all of which are diploid, $2n = 16$). In many cases the inter-species F_1's are completely sterile so that, to regain fertility, it has been necessary to make allotetraploids by colchicine treatment. In transferring genes from gooseberry (*R. grossularia*; *G* genome) to black-currant (*R. nigrum*; *B* genome) and vice versa, a technique of back-crossing to commercial diploid varieties via the triploids *BBG* and *BGG* respectively has met with considerable success[1–3]. Nevertheless, with a 2–3-year cycle between seed sowing and flowering, any short cut to the production from alloploids of fertile or partially fertile diploid plants having a minimal genic content from the donor species would offer considerable advantages.

A number of substances have recently been shown to be capable of inducing chromosome loss in fungi[4–6] and in *Allium*[7–10]. Several of these chemicals are being tested in the hope that some of them may have a similar effect on *Ribes* hybrids and thus be capable of inducing the formation of diploid sectors, having a limited content of donor genome, in *BBGG* and similar alloploid plants. Results are reported here from the use of one of these substances, *para*-fluorophenylalanine (*p*FPA), in a pilot experiment.

Aqueous solutions of *p*FPA of 1/200, 1/500, 1/1,000 and 1/10,000 were used, the material being dissolved in 0·1 N sodium hydroxide before dilution; a trace of 'Triton *X*-100' was added as a wetter. Four methods of application were used: (1) injection into young succulent tissue; (2) absorption by means of a fine cotton wick threaded through young stems just below the growing point; (3) absorption by placing the growing point in the solution; (4) absorption by placing leafy decapitated shoots in polythene bags wetted with the solution.

In all, 47 growing points of *BBGG*, *BBBG*, *BGG* and *BGGG* plants were treated during the period July 4–12, 1962. Apart from the death of some shoot-tips and the production of necrotic areas in some others, no marked symptoms were evident in 1962. In September 1962, single-bud cuttings were propagated from a number of shoots that had developed near the points of treatment. In spring 1963, abnormal stunted growth was noted in three of the cuttings from a *BBGG* ($2n = 32$) plant that had been treated with 1/200 *p*FPA by method (4), and the foliage of one of these was markedly crumpled and mottled (Fig. 1).

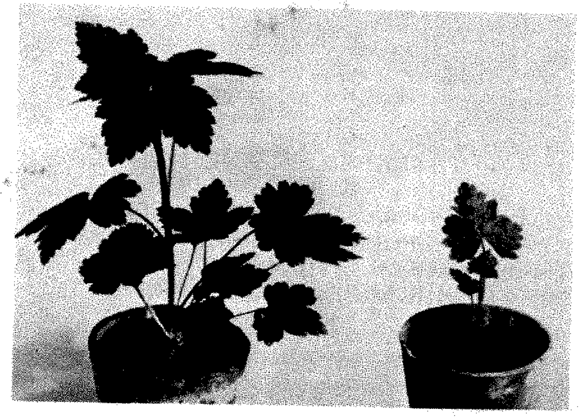

Fig. 1. Normal and abnormal growth of single-bud cuttings of a *BBGG Ribes* hybrid following treatment with *p*FPA

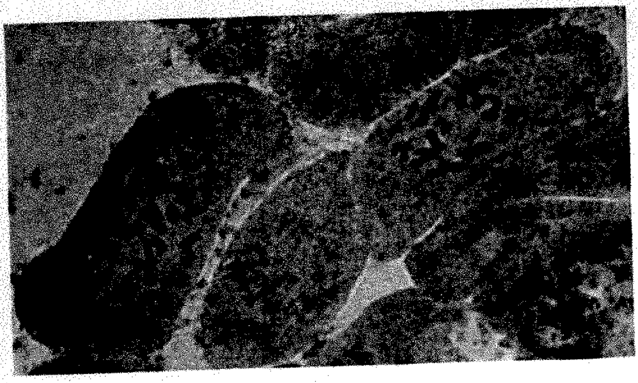

Fig. 2. Root tip cells, from the abnormal cutting shown in Fig. 1, with 20 and 32 chromosomes

Cytological examinations of root tip squashes from these three cuttings and from one that appeared normal were made in spring 1963. Cells having reduced chromosome numbers were found in all four. Of 30 root tips examined, 8 showed a low proportion of cells having chromosome numbers ranging from 8 to 24, including 3 cells having the diploid number $2n = 16$. Fig. 2 shows adjacent cells with 20 chromosomes and the normal number of 32 respectively. No cells with reduced chromosome numbers were seen in root tips of untreated cuttings from the same *BBGG* parent.

For plant breeding purposes, a technique capable of inducing the formation of homogeneous sectors of diploid tissue would be required. The extremely low proportion of diploid cells found in root tips following *p*FPA treatment, and the fact that all three abnormal shoots rapidly reverted to apparent normality, indicate that the technique described here will need considerable modification. Analogy with our experience of colchicine treatment of *Ribes* hybrids, where the growing points of very young seedlings are considerably more sensitive than are shoots of mature plants, suggests that sensitivity to *p*FPA will also be greater in young seedlings. The treatment of such seedlings with *p*FPA will be attempted next season.

VETERINARY SCIENCE

Experimental Scrapie in Goats: a Modification of Incubation Period and Clinical Response following Pre-treatment with Normal Goat Brain

SCRAPIE is a naturally occurring, experimentally transmissible disease of sheep, the causal agent of which has not been identified. The disease has been produced experimentally in goats[1], in which species the incubation period ranges from 7 to 23 months[2]. Attention has been directed to similarities between the scrapie agent and the agent responsible for allergic encephalomyelitis, and although these two diseases are quite unlike pathologically, it has been suggested that similarities in pathogenesis may exist[3].

It was decided, therefore, to attempt the 'sensitization' of goats with a large intraperitoneal inoculation of normal goat brain, and later to expose the animals to an intracerebral test dose of scrapie goat brain.

The results of 2 experiments indicated that goats pre-treated with normal goat brain reacted more rapidly and more violently to the test inoculum than did untreated control animals.

The goats used were cross-bred animals from the Compton flock, reared in a scrapie-free environment. Normal brain inocula were prepared from a homogenate held at −18° C of 2 brains from clinically healthy goats of the Compton flock. In the first experiment, the normal brain inoculum was 100 ml. intraperitoneally of a 10 per cent suspension in physiological saline; 5 goats were inoculated at birth, and 3 at 15 days of age. In the second experiment, 3 newly born goats each received 100 ml. of a 10 per cent saline suspension of normal brain intraperitoneally, and 4 were given the same volume by the same route but in the form of 10 × 10 ml. inoculations at weekly intervals. Material for this series of inoculations was drawn each week from a pool of 10 per cent brain suspension held at 4° C.

The intracerebral test dose of 1·0 ml. of the supernatant of a lightly centrifuged 10 per cent suspension in physiological saline of scrapie goat brain of the scratching type[4] was given to all animals 10 weeks after the single 100-ml. preparatory intraperitoneal inoculation of normal brain, or (in the second experiment) 1 week after the final 10 ml. preparatory dose. The scrapie brain used in the first experiment was from a pool of 8 homogenized brains that had been held at −18° C for 3 months. In the second experiment, a pool of 3 different homogenized scrapie goat brains held at −18° C for 2 months was used.

The results of the 2 experiments are given in Figs. 1 and 2, from which it will be seen that, in both experiments, the incubation period for the occurrence of clinical scrapie was significantly longer in the 5 untreated goats than in the 15 pre-treated animals ($P = 0{\cdot}001$). In the first experiment there was no significant difference between the goats pre-treated at birth and those pre-treated

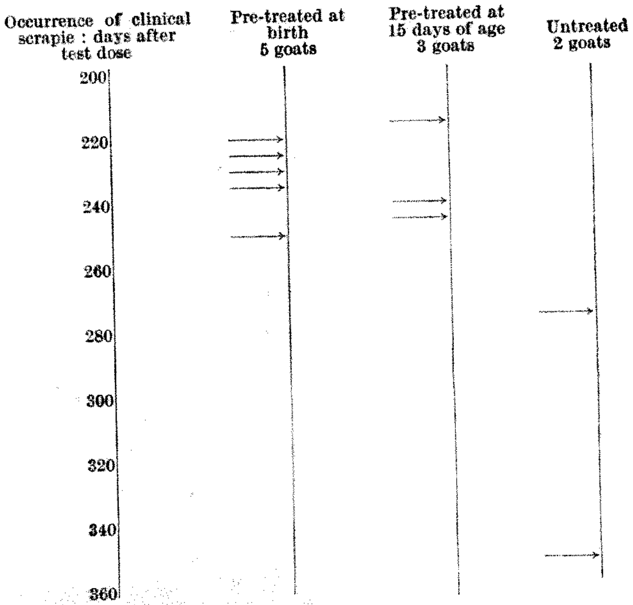

Fig. 1. First experiment. The occurrence of clinical scrapie in goats (*a*) pre-treated by intraperitoneal inoculation of 100 ml. of a 10 per cent suspension of normal goat brain at birth, or at 15 days of age (*b*) untreated. The intracerebral test dose was given ten weeks after pre-treatment

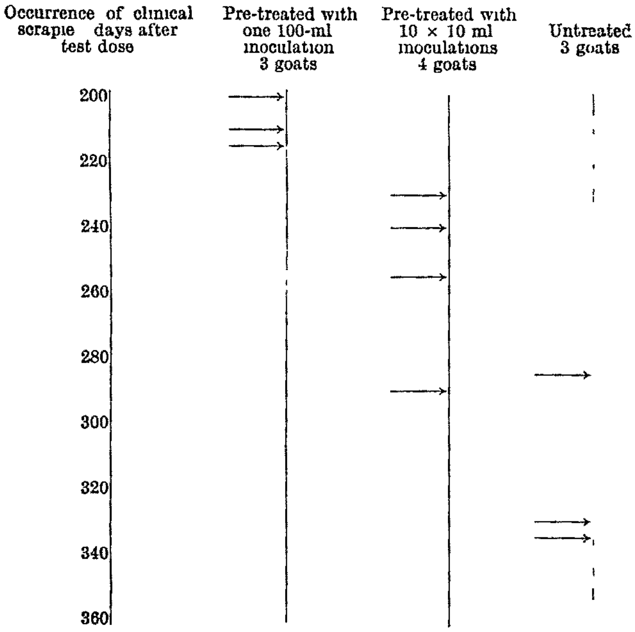

Fig 2 Second experiment The occurrence of clinical scrapie in goats (*a*) pre-treated by intraperitoneal inoculation of 100 ml of a 10 per cent suspension of normal goat brain at birth, or of 10 × 10 ml inoculations at weekly intervals from birth (*b*) untreated The intracerebral test dose was given ten weeks after the single 100-ml pre-treatment inoculation, or one week after the final 10-ml inoculation

at 15 days of age In the second experiment, the apparent slight difference between the group of 3 animals pre-treated with a single 100 ml dose at birth, and the group of 4 animals pre-treated from birth with 10 inoculations each of 10 ml at weekly intervals, was not significant ($P = 0\ 057$)

With one exception, the incubation periods for all animals in both experiments were within the 7–23 month range previously reported, the exceptional animal (Fig 2) developed clinical disease at 6 75 months, which is the shortest incubation period that we have noted in more than 350 cases of experimental scrapie in goats

In addition to the difference in incubation periods between untreated and pre-treated goats, there was a clearly marked difference in the severity of the clinical disease In the pre-treated animals the disease appeared suddenly, and scratching at the base of the neck was so severe that in 10 of the 15 animals there was bleeding followed by scab formation By contrast, in the 5 untreated animals the disease developed slowly, and scratching was much less violent

In both experiments, the intracerebral test dose was a suspension of scrapie goat brain It is not clear, therefore, whether the scrapie agent *per se* was affected by treatment, or whether the brain material in which the agent was held was the important element in the reaction Further experiments on this point are in progress

Zlotnik and Rennie[5,6] have recently considered the part that immunological tolerance may play in modifying the response of mice to a test inoculation of scrapie sheep brain In one series of observations they considered it possible that immunologically tolerant mice might have been rendered resistant to a scrapie test dose given by the subcutaneous route, but in later experiments they recorded that mice that were presumed to be tolerant to normal sheep tissue developed scrapie more or less at the same time as untreated control mice

The mechanism of the apparently enhanced clinical response of pre-treated goats is obscure Speculation on its nature would be unprofitable without further experimentation. However, from a practical point of view, pre-treatment with normal brain might be a useful technique for enhancing the clinical response of goats (and possibly, also, of other susceptible species) to experimental scrapie

SOIL SCIENCE

Interaction between Calcium Carbonates and Bentonite Suspensions

CALCIUM carbonate in soil is generally assumed to behave like pure calcite Equations relating calcium carbonate solubility to carbon dioxide pressure have been given, though their application to calcareous soils has not yet been tested thoroughly[1,2] Thus, usually only the system $CaCO_3$–CO_2–H_2O is considered, neglecting a possible interaction between the carbonates and other soil components[1–3]

Recently we found[4] that although the self-diffusion rate of calcium-45 into ground fractions of pure dolomite and calcite, as well as into unground calcium carbonate precipitate, was in accordance with expectations, the observed diffusion into comparable fractions of a commercial lime (*EMKAL*), consisting of ground marl, stopped after several hours As a possible explanation for this phenomenon might be an interaction between the calcite and, for example, silicate containing water in the marl deposit, it seemed warranted to investigate the behaviour of pure calcite in suspensions of soil clays

For this purpose suspensions of the fraction smaller than 5μ were prepared by grinding large-size crystals of dolomite and calcite The same fraction was separated from the commercial lime Also prepared was a suspension of calcium bentonite, consisting of particles smaller than 2μ of Wyoming bentonite saturated with calcium by repeated washing with 0 5 N calcium chloride and subsequent removal of excess salts All suspensions were made up so as to contain about 0 009 N calcium chloride.

Next the amount of calcium exchangeable against calcium-45 was determined as a function of time for all suspensions prepared and for mixtures of known composition of calcium bentonite with one of the foregoing carbonates Details of the procedure used are given in ref 4

If there were no interaction between the bentonite and the carbonates, obviously the total amount of calcium isotopically exchangeable against calcium-45 in a given time period in the mixed system should sum up to the calculated contribution of the two components, that is, clay and carbonate As is shown in Table 1, this is true for the mixture clay-*EMKAL*, but not for the mixtures of bentonite and the pure calcite In the latter case the self-diffusion of calcium-45 was impaired to a degree related to the ratio clay calcite

The reason for this phenomenon could be either the direct adsorption of clay on the carbonite particles (thus impeding the diffusion of calcium-45 into the crystals), or the interaction between the carbonate particles and molecular decomposition products of the clay—presumably silicates

In order to test the second possibility the foregoing experiments were repeated, this time replacing the bentonite by its dialysate or by a dilute solution of sodium silicate Although the exact composition of the dialysate was not determined, it is known that silicates were present.

Table 1

System			Isotopically exchangeable calcium microequivalents				
			Calculated contribution on basis of pure materials				
Carbonate	Time of shaking (h)	Bentonite/calcite (g/g)	Carbonate	Bentonite	Carbonate + bentonite	Experimental results of the mixture	Differences between calculated and experimental results
Calcite 1*	70	0.4	3.8	48.1	51.9	45.6	− 6.3
,,	192	0.4	7.3	55.2	62.5	55.1	− 7.4
Calcite 2*	98	0.06	225	16	241	202	− 39
,,	98	0.14	203	45	248	163	− 85
,,	98	0.27	181	106	287	141	− 146
EMKAL	70	0.29	9.4	48.7	58.1	59.8	+ 1.7

* Two degrees of grinding

As is shown in Table 2, the dialysate and the sodium silicate exhibited the same impeding action on the self-diffusion of calcium-45 into carbonates as the clay itself.

From this one can conclude that the observed decrease in the diffusion rate of calcium-45 into carbonates on contact with clays is due to the interaction between the surface of the calcium salts and dissolved compounds, presumably silicates, causing a surface coating of the carbonate particles with calcium silicate. With this explanation one has to assume that interaction with clays or other compounds has already occurred on the surface of the calcite particles of the commercial lime *EMKAL*, which therefore exhibited no further interaction with additional amounts of clay.

The question arises now as to the self-diffusion of calcium-45 into carbonates of calcareous soils. The nature of this process might be indicative with respect to the properties of the carbonate surface in these soils.

In a preliminary experiment, one Israeli calcareous soil containing 39 per cent of calcium carbonate was tested. Solutions labelled with calcium-45 were added to suspensions of the soil and the radioactivity of the supernatant was measured after different periods of shaking. The results show that there was a fast isotopic exchange in the first 2–3 h, after which there was no more exchange for more than a thousand hours, in contrast to the ever-continuing diffusion in similar experiments with pure calcite, dolomite and calcium carbonate precipitates[4].

This indicates that there was practically no self-diffusion of calcium-45 into the carbonates in the tested soil. On the basis of estimated surface area of the carbonates in the soil and assuming a diffusion constant of the order of magnitude of that of calcite[4], it could be shown that self-diffusion of calcium-45 would have been easily detected. One may suggest, therefore, that the carbonate particles in this soil were coated with compounds which did not allow or at least reduced considerably, the self-diffusion of calcium-45. This may also explain the observation[5] that calcium of the limestone did not interfere to any important degree with the isotopic exchange of calcium-45 in calcareous soils. It is interesting to note that the presence of some type of coating of carbonate particles has been suggested before by other workers[6].

Table 2

System		Radioisotopically exchangeable calcium (μequiv/g)		
Carbonate	Added solution	Time of shaking (h)	Calculated on basis of pure carbonate	Experimental results
Calcite 2	Dialysate 1*	98	> 580	44
	Dialysate 2†	98	> 200	25
Dolomite	Dialysate 2†	50	> 290	75
$CaCO_3$ (Merk Reagent)	Dialysate 2†	144	46	11
		462	> 80	35
	Sodium silicate	144	72	21
		462	> 120	21

Evidence against Relationships between Root Cation Exchange Capacity and Cation Uptake by Plants

DICOTYLEDONOUS plants usually contain a larger proportion of divalent to monovalent cations than monocotyledons. The cation exchange capacity of the roots of dicotyledons is generally larger than that of monocotyledons[1] and many results, starting with Mattson's[2], have been published indicating a relationship between root cation exchange capacity and differential uptake of divalent and monovalent cations. Huffaker and Wallace[3] explained the good relationships they obtained between cation exchange capacity of roots and concentrations of potassium, calcium and magnesium of several plants, grown in soil and sand, on the basis of Donnan distribution. Other workers[4–7] have shown that the cation exchange capacity of plant roots grown in soil-less cultures is not constant but can be altered by changing the composition of the nutrient solutions, in particular, larger cation exchange capacity values have been associated with increased levels of nitrogen. Recently it was reported that the sum of the cations in plants on poor soils was positively correlated with the root cation exchange capacity of the plants[8].

An experiment we made with Italian ryegrass (*Lolium multiflorum*) did not support any of the foregoing relationships but showed that (1) the differential uptake of mono- and di-valent cations was not related to root cation exchange capacity, (2) root cation exchange capacity was constant and did not vary with increased nitrogen in the grass, (3) root cation exchange capacity was not correlated with the sum of the cations in the grass.

Italian ryegrass was grown from seed in a clay loam soil in the greenhouse for 9 weeks during October–December. Daylight was supplemented with 400-W *HPMV* fluorescent lamps to give approximately 200 cal cm^{-2} day^{-1} during an 18-h day. The soil was kept at three constant

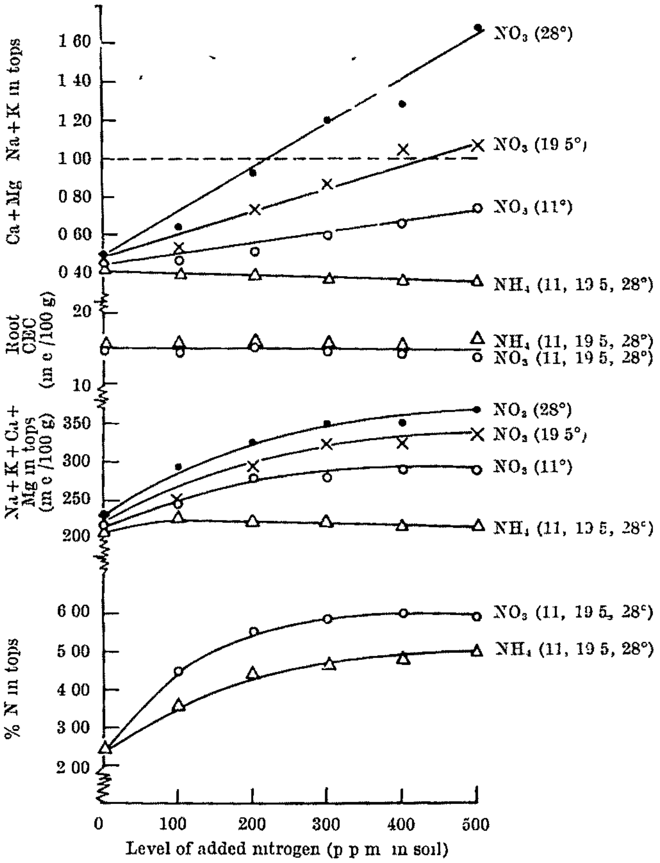

Fig 1 Effect of soil temperature, different levels of NO_3—N and NH_4—N on Ca + Mg Na + K ratio, sum of the cations, percentage nitrogen, and root cation exchange capacity (CEC) of Italian ryegrass

temperatures, 11°, 19 5°, 28°, in large water tanks, and uniform air temperatures were maintained in the foliage with circulating fans Six levels each of NO_3-N or NH_4-N (0-500 p p m) along with a uniform dressing of potassium, calcium, magnesium, phosphorus and sulphur were thoroughly mixed into the soil 'N-serve'[9] (2-chloro-6-(trichloromethyl pyridene)) was applied to the soil at 10 p p m to inhibit nitrification where NH_4-N was used

The figure gives measurements, on an oven-dry basis, of per cent nitrogen, sum of the cations (Na + K + Ca + Mg in m equiv /100 g) and the ratio of divalent to monovalent cations (Ca + Mg Na + K both in m equiv /100 g) in the tops of the plants and cation exchange capacity[10] (m equiv /100 g) of the roots The mineral contents of the roots were not measured, but it is doubtful whether including them with the mineral contents of the tops would have altered the results, root weights were always much less than those of the tops and at 28° and with much NO_3-N were only 10 per cent of total dry matter Averages were used when differences were small The results showed

(1) The ryegrass (a monocotyledon with small root cation exchange capacity), supplied with much NO_3-N and grown at high soil temperatures had a cation composition resembling that of a dicotyledon, that is, it absorbed more divalent than monovalent cations (Ca + Mg Na + K > 1) At low soil temperature and at all levels of NO_3-N the plants had more monovalent than divalent cations although the Ca + Mg Na + K ratio did increase with increasing NO_3-N Where NH_4-N was given, the divalent to monovalent cation ratio remained small at all soil temperatures and at all levels of NH_4-N

(2) The cation exchange capacity of the roots was not altered by soil temperature or by level or form of nitrogen, even though the percentage of nitrogen in the tops became greater with increasing levels of nitrogen, percentage nitrogen was always larger with NO_3-N than with NH_4-N

(3) The sum of the cations in the grass tops was not correlated with the cation exchange capacity of the roots, it did increase, however, with soil temperature and percentage nitrogen and was greater with NO_3-N than with NH_4-N, as found by Cunningham[11]

PSYCHOLOGY

Evidence for a Physiological Explanation of the Waterfall Phenomenon and Figural After-effects

IN the rabbit's retina ganglion cells have recently been found which signal the direction of motion of objects moving in the visual field[1,2] These cells give brief responses at 'on' and 'off' to lights falling in their receptive fields and they give vigorous responses to moving spots, but only when these are moved in certain directions through their fields Motion in the 'preferred' direction gives the maximum discharge, while motion in the opposite, 'null', direction, causes no response The 'preferred' direction differs in different units thus which of a set of cells are active conveys information as to the direction of motion of objects in the visual field The frequency of the discharge depends greatly on speed and direction of motion, but is only slightly influenced by the intensity of the moving stimulus spot Furthermore, the discharge occurs for the same direction of motion with a black spot as with a white spot This behaviour is what one might expect in units of which the function is to abstract direction of motion from the pattern of light falling on the retina

While performing experiments on these units we made some observations on the effects of long-continued exposure to moving stimuli These observations are incomplete, but they are sufficient to suggest a physiological basis for the after-effects of sustained excitation by motion Since the observations will not be followed up in the near future they are briefly reported here

The activity of single units was recorded from electrodes inserted into the retina of the unopened rabbit's eye A directionally selective unit was found, its receptive field located, and the preferred direction determined To excite it, we rotated a large black disk carrying an irregular pattern of pieces of paper The disk was much larger than the receptive field, and the direction of motion of the part coinciding with the receptive field could be changed by shifting the axis of rotation of the disk Fig 1 shows what happens during and immediately after periods of exposure to motion in the preferred and null directions lasting 1 min The number of impulses in each second is plotted vertically, time horizontally For the first 15 sec the disk was stationary and the unit showed the normal, irregular, maintained discharge At the arrow, in the top graph, motion in the preferred direction was started The angular velocity at the eye was about 15°/sec The impulse frequency immediately rose to about 60/sec, but declined to about 25/sec during the first 15–20 sec. During the next 40 sec it fell only slightly further. Motion was stopped 57 sec after it had started, and the impulse frequency dropped abruptly to zero—below the maintained level preceding the stimulus. During the following 0·5 min it climbed slowly back to the level of the initial maintained discharge.

In the lower graph, the same sequence was repeated on the same unit, but this time the motion was in the null direction. There was no significant change in impulse frequency during the period of stimulation, nor during the period following it. (The peak just before the motion stopped should be disregarded, for it was caused by unintentional lateral movement of the disk while preparing to stop it spinning.) We were expecting to find some reduction in the maintained discharge during the motion in the null direction, and possibly some rebound excitation following it, for it is possible to inhibit the maintained discharge of such a unit by careful movements of single spots of light in the null direction. But in this experiment new spots were continually entering the field, and old ones leaving it: possibly the resulting 'on' and 'off' effects prevented a reduction in the maintained discharge. At all events we never recorded a clear-cut reduction in experiments of this type, nor did we ever observe definite rebound excitation in the period following stimulation.

We have seen similar changes in a number of units, and believe that the behaviour shown in Fig. 1 is typical for the units which signal direction of motion. In one case we maintained stimulation for 3 min without greatly changing the magnitude or duration of the after-effects. In another we stimulated for 0·5 min, and thought that the effects were less pronounced.

For reasons to be given in the following communication, it seems unlikely that similar effects occur at a retinal level in man. However, in the rabbit's retina we have a specimen movement analysing mechanism, and it is reasonable to ask if the observed changes fit in with the subjective after-effects of movement. Similar changes to those described here may well occur in lateral geniculate or cortex of man.

The initial adaptation of the discharge fits in well with the decline in the sensation of movement which is noticeable during the first 0·25 min of observation. A similar decline in vividness of inspection figures has been described in experiments on figural after-effects and Gibson-type illusions[3].

The after-effects themselves may be explicable by the reduction in maintained discharge in the period following excitation. In the figure itself, upper and lower graphs were obtained from a single unit by reversing the direction of motion, but one must remember that there is a large population of directionally selective units, some of which will have their null direction the same as the preferred direction of this particular cell. It is reasonable to presume that such a cell would behave as in the lower graph while the cell actually being examined behaves as in the upper graph. Considering these two cells, one sees that before the stimulus their maintained discharges would be roughly equal. During the stimulus the one, the preferred direction of which coincided with the direction of movement, would be more active than the other, while in the period immediately following the stimulus the other one, which normally signals motion in the reverse direction to that of the preceding stimulus, would be the more active and might give rise to the sensation of reverse movement. Thus the after-effects of motion may result from the temporary imbalance of the maintained discharges of cells responsive to motion in opposite directions. Our results suggest that the imbalance is caused by a reduction in discharge of the units that have been excited rather than by rebound excitation of other units.

The duration of the suppression of the maintained activity seems to coincide with the duration of the shorter-lived after-effects, such as the waterfall phenomenon itself, and the curved line illusion. Some figural after-effects are reported to be much longer-lasting, though in these cases the period of exposure to the stimulus has also been longer than we have used. Similarly the duration of exposure to movement required to cause suppression seems to agree with that required to cause the after-effect, though on this point our evidence is very incomplete.

The agreement of time-scales is encouraging, and there are two details of the subjective effects which seem to provide additional support. First, the magnitude of the after-effect is always limited, thus reverse motion is always rather slow. If the imbalance is caused by suppression of the maintained discharge this feature would be expected, for the rate of the suppressed unit cannot drop below zero, and the maintained level of discharge of the unstimulated unit is not high. Second, Wohlegemuth (1911) reported that exposure to motion first in one direction, then in the other, led to a state where neither direction of motion can induce an after-effect. This is readily explained if the initial exposure to alternating directions of motion suppresses the maintained discharge of both units, so that imbalance by suppression is no longer possible. Imbalance by increasing the discharge would still occur during exposure to moving stimuli, thus explaining why the subject is not rendered insensitive to motion by the treatment.

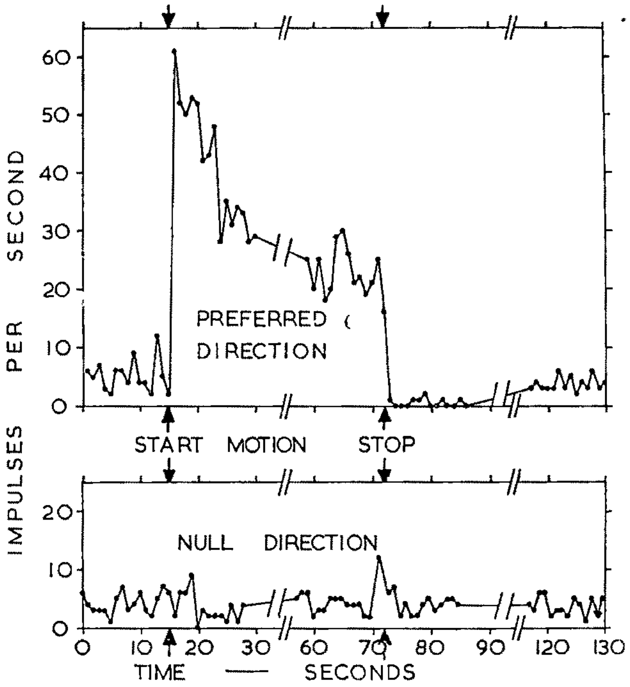

Fig. 1. Effects of stimulating a directionally selective unit for 1 min by motion in the preferred and null directions. Impulses/sec are plotted vertically, time horizontally. The maintained activity is suppressed following 1 min of excitation by motion in the preferred direction. Motion in the null direction has no significant effect, the peak at 70 sec being an artefact

Though the evidence is new, this explanation for after-effects is not, and is substantially the same as that advanced by Exner and modified by Wohlegemuth (1911). Originally it was framed in terms of 'tonus', 'drainage', and 'fatigue', but it does not depend on these notions and their idea can easily be translated as temporary suppression of the maintained discharge. Further, many of the after-effects of motion can be paralleled by the after-effects of exposure to contours, curved lines and tilted lines, as shown by Gibson[4], and Kohler and Wallach[5] (see also McEwen's review[3], and various authors[6]). It is plausible to suggest that suppression of the maintained discharge lies behind many of these effects, but notice that there are two requirements for such an explanation to hold up. First, the units concerned must have a maintained discharge; secondly, they must be arranged in reciprocally active pairs, so that the suppression of one unit can lead to subjective effects similar to those caused by increased activity in the other of the pair

Finally, it is interesting to ask if the argument can be used in reverse If after-effects are due to the imbalance of maintained activity of units specifically excited by features of the inspection figures, can one deduce the nature of the units which analyse sensory data from the nature of the after-effects which are readily produced ?

Inter-ocular Transfer of Movement After-effects during Pressure Blinding of the Stimulated Eye

THERE is evidence that pressure blinding abolishes all activity of the ganglion cells of the retina[1] It has been suggested[2] that the after-effect of exposing an eye to a moving stimulus (the waterfall illusion, see preceding communication) may be caused by the reduction of maintained discharge of the directionally sensitive retinal ganglion cells which were stimulated during the period of inspection, leaving the maintained activity of those which would signal the reverse motion unbalanced. If this is correct, then pressure blinding the eye during the period immediately following stimulation should abolish the effect Unfortunately, one is not clearly aware of the movement illusion if there are no objects that one can see as moving, and pressure blinding prevents seeing. One therefore has to perform the test on the illusion transferred to objects seen with the other eye Incidentally, it is interesting to note that the existence of this transfer has often been taken as convincing evidence for the central origin of the after-effects, but the transfer would be explicable on the hypothesis that it is due to suppression of maintained discharge even if this occurred only in the retina

The test was performed as follows A subject observed monocularly a rotating object which was either a spiral, or an irregular pattern of black marks on a white ground After 30 sec he applied pressure with his finger, trying not to disturb fixation, until complete fading had occurred (usually about 15 sec) The rotation was then stopped and the pressure-blinded eye covered, but the pressure was maintained The subject opened his other eye, observed the stationary disk, and reported on the appearance of movement

We ourselves and two other subjects were all able to get very clear transfer of the after-effect in spite of complete pressure blinding of the pre-exposed eye The completeness of pressure blinding was checked after the illusion had been observed No similar effects occurred when the eye was pressure blinded without the exposure to movement We compared the after-effect transferred from a pressure-blinded eye with that transferred from an eye for which the effect of pressure had been mimicked by dimming, and finally extinguishing, the light illuminating the rotating disk The after-effect from the pressure-blinded eye seemed as vivid, and lasted about as long as that from the control

The result shows that subjective movement after-effects are not caused by suppression of the maintained discharge of directionally selective ganglion cells in the retina of man The only escape from this conclusion would be if directionally selective units were unaffected by pressure blinding, or possibly if after-effects occurred both retinally and centrally. The observation does not decide which part or parts of the hypothesis are wrong It is not known whether human, primate, or monkey retinæ have directionally selective units, and it is certainly quite likely that in these species the analysis of direction of movement of objects in the visual field occurs at a higher level in the nervous pathway If that is so, then suppression of geniculate or cortical maintained activity remains a plausible explanation of the waterfall phenomenon.

Scaling and Personal Questionnaires

STEVENS'S[1] classification of types of scaling according to their group structure appears insufficient, since a higher ordered metric[2,3] and an interval scaling both belong to the same group, namely, the linear group (an interval scaling according to Stevens and a higher ordered metric scaling because the only function $f(x)$ such that for all a, b, c, d, if $|a-b| > |c-d|$ then $|f(a)-f(b)| > |f(c)-f(d)|$ is a linear function), yet they contain different amounts of information

The following alternative definition and classification are suggested A scaling of a set of n objects on a single dimension is the unique specification of a certain relationship (varying with the type of scaling) between pairs of elements, the elements being either ordinates of objects or functions thereof (depending on the type of scaling) (For example, an ordinal scaling specifies, for all pairs of objects, which has the greater ordinate an interval scaling specifies the ratio between all pairs of differences between the ordinates of objects, the ordinates themselves are in all cases generally not known) Scalings may consequently be classified according to relationship and according to elements this two-way scheme is illustrated in Table 1 with four of the commonest types of scaling

Table 1 TWO-WAY CLASSIFICATION OF FOUR TYPES OF SCALING

Elements	Relationship Direction of inequality	 Value of ratio	
Ordinates	$A >< B$? Ordinal	$A/B =$? Ratio	For all A, B
Differences between ordinates	$AB >< \overline{CD}$? h o m	$\overline{AB}/\overline{CD} =$? Interval	For all A, B, C, D where possibly $B = C$

A, B, C, D are ordinates of objects

A general direct method suggested by the foregoing definition (particular cases of which are well known) of obtaining a psycho-physical scaling, along a subjective dimension, of a set of objects by a single subject, is to present him with each of the possible appropriate subsets of objects, pairs (ordinal and ratio scalings) or pairs of pairs (higher ordered metric and interval) and ask him to specify the relationship, to make a judgement of greater or less (ordinal and higher ordered metric) or to estimate the ratio (interval and ratio) In the case of higher ordered metric and interval scalings, however, the number of pairs of pairs of objects, $3\binom{n+1}{4}$, rapidly becomes unmanageable with increasing n, and simpler techniques are available (ranking for higher ordered metric and interval estimation[4] for interval)

The general method gives more than enough information for assigning scale values to objects The case of ordinal scaling has been dealt with by Kendall and Babington Smith[5], higher ordered metric scaling by Coombs[2] and Siegel[3], Torgerson[6] gives a least squares estimation procedure for ratio scaling, and there is an obvious adaptation of this procedure to interval estimation The redundant information may be used to test reliability (internal consistency)

A common feature of the various internal consistency tests given in the literature is that they examine all appropriate sets of three responses to verify that certain necessary relationships hold between them Thus, if a subject estimates that $E/F = r$ and $F/G = s$, then he should also estimate that $E/G = rs$ (where E F, G are elements) although some allowance will be made for imperfect estimation, and, a special case of this, if he judges that $E > F$ and $F > G$, then he should also judge that $E > G$ (There are also certain 'internal' relationships that should hold for higher ordered metric and interval scaling for the latter, if the subject judges that $\bar{AB} = d$ and $\bar{BC} = e$ where $A < B < C$ then he should also judge that $\bar{AC} = d + e$, for the former similar but more complicated relationships should obtain)

These methods may be used, *inter alia*, to scale features of the symptomatology of an individual psychiatric patient (for example, sets of situations which a phobic finds frightening), the objects usually being represented by cards bearing descriptions of the features preferably in the patient's own words A particularly interesting case occurs when the objects are different degrees of intensity of a particular symptom (for example, *A*, 'I feel very depressed'; *B*. 'I feel rather depressed', *C*, 'I feel only a little depressed', *D* 'I do not feel depressed at all') After they have been scaled by the patient, that is, after he has specified all the relationships involving them, and if the scaling can be assumed to be sufficiently permanent, then the patient's position on the continuum can on different occasions be introduced as an extra object, and by asking him to specify all relationships involving it and the other objects a scale value can be assigned to it for each occasion these further specifications will thus constitute administrations of a personal questionnaire which will measure fluctuations in the intensity of the symptom For each administration, as a different conclusion of the initial scaling, the usual internal consistency checks will be available

To each type of scaling will correspond a type of personal questionnaire the first type to be described, and almost the only one which has so far been used at all extensively, is Shapiro's[7], which suggested the present generalization, and which is a partial higher order metric type with $n = 3$ (It has been found possible to generalize this to the case where $n \geq 4$) It is not always necessary that the initial scaling should be of the same type as the questionnaire scaling For example, Shapiro's type uses an initial ordinal scaling, and, surprisingly, the interval and ratio types do not need any initial scaling There are a number of such mixed types, of which those involving higher order metric scaling are the most intricate

MISCELLANEOUS

Detecting Fingerprints on Paper

DURING the continuation of an investigation[1] into the factors affecting the resistance of paper to attack by atmospheric pollution, we found that fingerprints were affecting our results Further investigation suggested that a method for detecting fingerprints on paper could be developed Fuller details are to be published shortly, but in essence the method consisted of exposing the sample of paper to radioactive sulphur dioxide at a concentration of about 10 p p m , followed by autoradiography Sulphur dioxide was picked up preferentially in the regions contaminated by the fingers, and this caused a greater darkening of the X-ray film An example of one of the prints obtained is shown in Fig 1 The specific activity of the sulphur dioxide was about 1 mc /m mole, the time of exposure about 12 h and the time for autoradiography one week

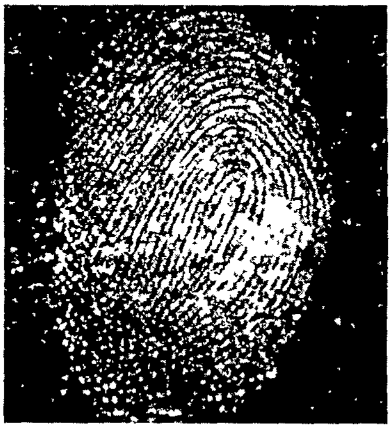

Fig 1

Since sulphur dioxide also combines with paper especially with the more impure grades, it did not appear to be ideal for this work and formaldehyde carbon-14 was therefore tried[3] The sample was exposed for 30 min to the vapour from ^{14}C-paraformaldehyde of specific activity 86 3 µc /mg at room temperature and left in contact with X-ray film for 15 h When developed the film showed a strong outline of the paper, but a weak and sketchy image of the print There was clearly too much general reaction between the formaldehyde and constituents of the paper to permit the fingerprint to develop

Both the methods at present used[2] for the detection of fingerprints on paper depend on the production of a colour, so that the method described here offers an advantage for use with coloured papers Research is called for to determine if there are other compounds more suitable for providing a convenient and sensitive method of detection using the same principle[3]

Institute of Metals (at 17 Belgrave Square, London, S W 1) at 7 p.m Dr C A Clark 'Some Recent Developments in Magnetic Alloys"

Friday, January 3

British Mycological Society (in the Department of Mechanical Engineering (E 1 Building), City and Guilds College, Exhibition Road, London, S W 7), at 10 45 a m —General Papers

Saturday, January 4

London County Council (at the Horniman Museum, Forest Hill, London, S E 23), at 3 30 p m —Dr Mary E Gillham "Wild Life in Australia' (Coloured Slides) *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Librarian (with an honours degree, professional qualifications as a librarian, and responsible experience in a specialist library of high standing) —The Academic Registrar, Brunel College, Woodlands Avenue, London W 3 (January 8)

University Lecturer (preferably with qualifications in medicine and biochemistry) in Biochemistry—T D Kellaway, Secretary of the Appointments Committee, Department of Pathology, The University, Tennis Court Road, Cambridge (January 9)

Assistant Lecturers (2) in the Department of Chemistry—The Secretary, Battersea College of Technology, Battersea Park Road, London S W 11 (January 10)

Lecturer/Assistant Lecturer (preferably with qualifications in analysis) in the Department of Mathematics, University of Ghana—The Registrar, University of Ghana, P O Box 25, Legon, Accra, or The Assistant Registrar (Overseas), University of Ghana, 15 Gordon Square, London, W C 1 (January 10)

Lecturer (preferably with an active interest in some aspect of experimental botany] in Botany—The Registrar, Queen Mary College (University of London), Mile End Road, London, E 1 (January 10)

Lecturer (with experience in high energy nuclear physics) in Physics and a Lecturer (with an interest and experience in magnetic resonance) in Physics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E 1 (January 10)

Principal Scientific Officer (with a good honours degree and considerable postgraduate research, and preferably with practical experience of quantitative methods of population estimation, with experience of more than one taxonomic group, and an appreciation of statistics) in the Toxic Chemicals and Wildlife Section, Monk's Wood Experimental Station, Huntingdon, to direct work on insect populations—The Nature Conservancy (E), 19 Belgrave Square, London, S W 1 (January 10)

Research Fellow (with a first degree in biochemistry, chemistry or botany and research experience in biology) in Plant Biochemistry in the Department of Botany—The Registrar, Queen Mary College (University of London), Mile End Road, London, E 1 (January 10)

Lecturer (physicist or physical chemist, qualified in physics or physical chemistry and an interest in the application of physical techniques to biology and particularly macromolecules or electron microscopy) in the Department of Botany—The Secretary, University College, Gower Street, London, W C 1 (January 14)

Chair tenable in the School of Applied Science and Engineering Science—The Registrar, University of Sussex, Stanmer House, Stanmer, Brighton, Sussex (January 15)

Lecturer in Experimental Physics—The Registrar (Room 22, O R B) The University, Reading (January 15)

Lecturer or Assistant Lecturer in Applied Mathematics in the Department of Mathematics in the Faculty of Science—The Registrar The University, Manchester 13 (January 15)

Lecturer (with a degree in veterinary science or an appropriate degree in science) in Veterinary Anatomy at the University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London S W 1 (London and Brisbane, January 17)

Chair of Agricultural Chemistry and Head of the Department of Agricultural Chemistry and Soil Science at the University of Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 18)

Chair of Geology at Bedford College—The Academic Registrar, University of London, Senate House, London, W C 1 (January 30)

Associate Professor (with a higher degree and preferably a specialist in the field of power engineering) in the School of Electrical Engineering, University of New South Wales—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and The Appointments Section, University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (January 31)

Chair of Fluid Mechanics in the Department of Mechanical Engineering, University of the Witwatersrand, Johannesburg, South Africa—The Secretary Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (South Africa and London January 31)

Chairs of Mathematics—The Secretary, The University, Aberdeen (January 31)

Lecturer (dental, medical or science graduate, with bacteriological experience) in Dental Bacteriology, Turner Dental School—The Registrar, The University, Manchester 13 (January 31)

Lecturer (Grade II) in Pure Mathematics—The Registrar, The University, Senate House, Bristol 2 (January 31)

Turner and Newall Research Fellow for research in Engineering, Inorganic Chemistry or Physics (or possibly in an allied science)—The Registrar, University Registry, Clarendon Building, Oxford (February 8)

Assistant Professor in Anatomy—The Chairman, Department of Anatomy, University of Saskatchewan, Saskatoon, Sask , Canada

Assistant Professor of Theoretical Physics, to teach upper division physics courses—C E Wulfman, Chairman, Department of Physics, University of the Pacific, Stockton, California U S A

Grassland Investigator (single, between 25–35 years of age, with an honours degree in agriculture or an appropriate science and a minimum of three years experimental experience) with the Government of the Falkland Islands, to investigate, experiment and report on the best methods of developing and improving grasslands—The Director of Recruitment, Department of Technical Co-operation Eland House, Stag Place, London, S W 1, quoting Ref T/RC 213/48/01

Head (with a university degree, preferably in the physical sciences, a recognized diploma in librarianship, several years experience in a similar post, a very good knowledge of French and English, and preferably some knowledge of other European languages) of the Scientific Information Service and Librarian—The Head of Personnel, European Organization for Nuclear Research (CERN), Geneva 23, Switzerland, quoting Ref DD-SIS

Lecturer and an Assistant Professor in the Department of Philosophy—The Dean, Faculty of Arts and Science, University of Manitoba Winnipeg 19, Manitoba, Canada

Research Assistant (with a degree in biology and an interest in histochemistry), to work on problems of peripheral nerve disorders—Dr J B Cavanagh, Pathology Department, Guy's Hospital Medical School, London Bridge, London S E 1

Research Assistant (with a good honours degree in any branch of technology and some research experience), to take day-to-day charge of a research project on the mechanical properties of metals and non-metals—Dr R D Hoyle, Mechanical Engineering Department, Imperial College of Science and Technology, London, S W 7

Research Fellow (with a good degree or equivalent in any branch of science or engineering, a logical outlook and preferably some knowledge of statistics and research experience) in Information Science in the Department of Management and Social Sciences, for a four-year investigation of principles of information storage and retrieval—The Secretary Northampton College of Advanced Technology, St John Street London, E C 1

Senior Grade Biochemist in the Biochemistry Department—Dr D N Raine, Children's Hospital, Ladywood Road, Birmingham 16

Senior Lecturer (with experience in academic or industrial research and in teaching or direction of projects) in Physics—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N 7

Senior Zoologist (with an honours degree in zoology or equivalent and research or other experience in zoology) in the Veterinary Department Government of Kenya, for investigations into the treatment of trypanosomiasis research work in immunity both in the laboratory and in the field and to give advice on drug regimes in the various areas of the country—The Director of Recruitment, Department of Technical Co-operation, Eland House, Stag Place, London, S W 1, quoting Ref C1/RC 217/80/011

MICROMANIPULATORS

if you use a
MICROSCOPE
you need a
SINGER
FULLY PATENTED
MICROMANIPULATOR

Singer micromanipulators are used in most laboratories all over the world Three types available

Mk I Low power for magnifications ×1 to ×200

Mk II For magnifications ×1 to ×500

Mk III High power for magnifications ×100 to ×1,000 *plus*

The most advanced instruments for micromanipulation As described by Barer and Saunders-Singer with further improvements

Full details and demonstrations upon request to

SINGER INSTRUMENT CO. LTD.,
Fountain Court, 83 London St,
Reading, Berkshire, England

APPOINTMENTS VACANT

REPUBLIC OF THE SUDAN
MINISTRY OF AGRICULTURE
AGRICULTURAL RESEARCH DIVISION

Applications are invited from those suitably qualified to fill a vacancy for Senior Statistician and Statistician in the Gezira Agricultural Research Station at Wad Medani

Qualifications Honours degree in Mathematics or Statistics with postgraduate qualifications in Mathematical and Experimental Statistics

Experience Senior Statistician (post a)—considerable experience in the Design and Analysis of Experiments is essential Experience of research in more than one branch of Biometry is desirable, and knowledge of sample Surveys would be an advantage

Statistician (post b)—experience of research and application of Biometric methods is desirable

Duties The Senior Statistician would be in charge of the Statistical Unit at the Gezira Research Station and is responsible for the design and analysis of the more complicated experiments, the planning of surveys, etc He will be expected to advise other units on experimental techniques and on data analysis and processing The Statistician will be responsible for the projects and investigations allocated to him by the Senior Statistician

Terms Appointment will be on Short Term Contract for a period of five years in the salary range—Post a £S 1,225 to £S 2,210 with bonus, or £S 1 306 to £S 2 360 without bonus Post b—£S 1,225 to £S 1,900 with bonus or £S 1,306 to £S 2,026 without bonus (£S 1 = £1 0s 6d) The starting rate will be fixed according to age, qualifications and experience In the case of special qualifications a rate of pay higher than the maximum may be considered A cost of living allowance of approximately £S 187 per annum and outfit allowance of £S 50 is also payable At present there is no income tax in the Sudan Home leave accrues at the rate of seven days per month, with free air passage Government housing is provided at low rentals, or if not available a housing allowance will be granted A system of hire of basic furniture is being introduced

Requests for further details and application forms should be made to Appointments Section, Embassy of the Republic of the Sudan 3 Cleveland Row, St James's, London, S W 1 quoting reference 7-4/432 a or b Closing date January 15, 1964

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF ZOOLOGY

Applications are invited for a post of Research Assistant, sponsored by the United States Public Health Service, to undertake taxonomic and ecological work in the aquatic Oligocheata Candidates should hold a degree in zoology and should have an interest in ecology, freshwater biology or pollution studies The salary scale will be £750 by £25 to £850 per annum The possibility of working for a higher degree is not excluded Laboratory and field work will be involved

Applications, stating age, academic qualifications and experience, together with the names of two referees, should be received not later than January 10 1964, by the Registrar, the University, Liverpool 3, quoting reference number CV/482/N

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF PHYSICS

Temporary Contract Assistant required to construct and test electronic equipment for satellite instrumentation Candidates should have had experience with transistorized circuitry Salary up to £900 per annum according to age and qualifications Period of appointment two years

Applications in writing, giving details of age education and experience and the names of two referees should be sent to the Secretary and Registrar, the University Southampton, as soon as possible

STC

SELENIUM RECTIFIERS

University Graduates and Engineers with H N C are required to work on new products in our Selenium Rectifier development programme Vacancies exist in

PROCESS DEVELOPMENT
ELECTRICAL EVALUATION
APPLICATIONS

Experience with selenium or other semiconductors is desirable but not essential Rented (non-tied) accommodation is available for successful applicants

Apply to The Personnel Manager,

Standard Telephones and Cables Limited
SEMICONDUCTOR DIVISION—RECTIFIERS
Edinburgh Way, Harlow, Essex

BACTERIOLOGIST

UNILEVER RESEARCH LABORATORY, Colworth House, invites applications from bacteriologists for an appointment in a team investigating the intestinal flora of young farm animals

Please write for an application form to

THE STAFF OFFICER (FRR/245A), UNILEVER RESEARCH LABORATORY, COLWORTH HOUSE, SHARNBROOK, BEDFORD

UNILEVER RESEARCH

DARTMOUTH MEDICAL SCHOOL

Experienced electron microscopy technician or graduate assistant required for research on immunologic aspects of placental morphogenesis and homograft mechanisms Starting salary $4,000 to $6,000 dependent on qualifications and experience

Further particulars may be obtained from Dr M Galton, Department of Pathology, Dartmouth Medical School, Hanover, N H 03755, U S A

THE NATURE CONSERVANCY REQUIRE a Principal Scientific Officer for work in the Toxic Chemicals and Wildlife Section, Monks' Wood Experimental Station, Huntingdon, to direct work on insect populations Qualifications a good honours degree and considerable postgraduate research Preference will be given to applicants with practical experience of quantitative methods of population estimation with experience of more than one taxonomic group and with an appreciation of statistics Starting salary on scale £1 894 to £2 646 Superannuation F S S U —Applications, giving full details of age education, experience National Service, Natural History interests and other relevant information, with names/addresses of two referees to The Nature Conservancy (E), 19 Belgrave Square London S W 1, by January 10, 1964

GOVERNMENT OF THE FALKLAND ISLANDS

Grassland Investigator required to investigate experiment and report on the best methods of developing and improving grasslands Candidates must be between 25 to 35 years of age single, hold an honours degree in agriculture or an appropriate science and have a minimum of three years experimental experience Appointment on contract for one tour of three years Inclusive salary scale £1,600 to £2,000 a year Free passages Free medical and dental treatment

Apply, stating full name and giving brief particulars of qualifications to Director of Recruitment, Department of Technical Co-operation Eland House, Stag Place, London, S W 1, quoting C1/RC 213/48/01

UNIVERSITY OF SASKATCHEWAN
DEPARTMENT OF ANATOMY

Applications are invited for the position of Assistant Professor in Anatomy Salary range $7,000 to $9,300 according to experience Ample opportunities for research in various fields Good research facilities

Apply to chairman of the Department of Anatomy, Saskatoon, Sask , Canada

Optimum quality costs less when you specify

Continuous development of Isopad products enables us to say, confidently, that they are unequalled in quality of construction and long life, yet often cost less. Our catalogue lists the complete range and gives information about how to order. Please write for your copy.

Isomantle

LABORATORY HEATING EQUIPMENT

Recent Developments:

1) Both standard and popular Multisize ISOMANTLES are now made with built-in Energy Regulator.

2) Isopad EXTRACTION UNITS can have a Temperature Indicator for each position.

3) The new range of HEATING TAPES FOR LABORATORIES includes moisture proof and high temperature types.

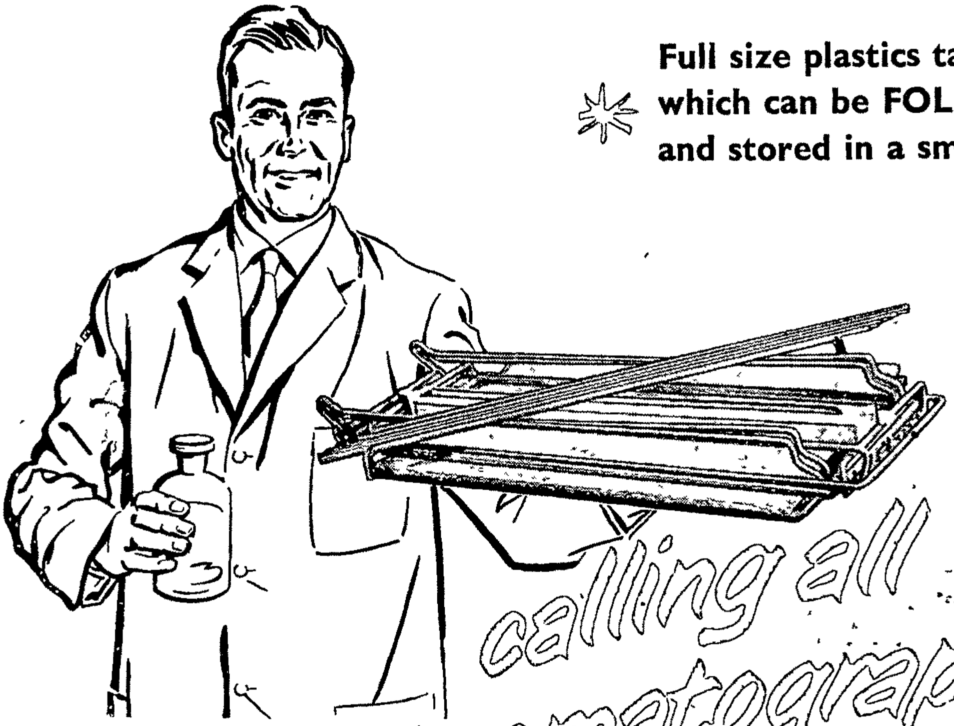
Full size plastics tanks which can be FOLDED UP and stored in a small space.



calling all chromatographers

with news of Chromatobags

It is frequently necessary to exclude wood and metals from paper chromatography apparatus, and all-glass equipment is consequently widely used, but glass is fragile.

NOW CONSIDER THE ADVANTAGES OF CHROMATOBAGS

- Inexpensive to transport
- No cleaning problems—unbreakable transparent containers are disposable when contaminated
- Quick-strip framework Convenient for folding up and storing in small space
- Airtight—resistant to all common solvents
- Complete accessibility to chromatograms
- Specially suitable for work with radioactive isotopes or highly toxic chemicals

HOW CHROMATOBAGS ARE USED

A Gallenkamp 'Chromatobag' consists of a readily demountable plastics coated framework which supports the solvent trough and the guide rods for the paper strips or sheets A tough flexible plastics bag draws up over this frame to form a 'tank' and the enclosure is rendered airtight by clipping the neck of the bag To replenish the trough or remove the chromatograms, the bag is opened and, if necessary, slipped down over the framework The bags are transparent so that the strips can be inspected when the bag is closed The design does not necessitate any special chromatography techniques, but rather simplifies procedure by enabling the user to reach wet chromatograms from the side instead of from the top 'Chromatobags' can be used equally satisfactorily for descending, ascending or two-dimensional work using paper strips or sheets. When the bags become old, soiled or contaminated they can be replaced very easily and their destruction presents no problem
